FAMILY HELPED BY AMATEURS

SON STRICKEN IN GERMANY

(Reprinted from the Williamsport Sun-Gazette) Mr. and Mrs. William J. Shannon recently learned that kindness can extend for thousands of miles.

On Sept. 1, the Shannons got a cable from their son, John, saying he was ill in Heidelberg Polyclinic Hospital, Heidelberg, Germany. He had been on vacation in Europe. He is head of the music dept. at Wyoming Seminary, near Wilkes-Barre.

Mrs. Shannon called the hospital, but was told that no John Shannon was listed.

"We were really worried," recalled Mrs. Shannon. "John wouldn't have cabled unless he was seriously ill."

The Shannons tried to contact their son by cablegram but with no success.

Finally they went to the Red Cross, but that attempt also failed. The Red Cross suggested however, that Mr. and Mrs. Shannon try to contact Germany by ham radio.

Mrs. Shannon's brother, Robert Stout W3NEN, put them in touch with Donell Godfrey K3QFW, the past president of the West Branch Amateur Radio Club.

"Mr. Godfrey is the hero of this story," said Mrs. Shannon." He's the one who helped us get into contact with someone who knew about our son."

On his radio, Don contacted Guenther Herzog in Hemer, Germany, about 250 miles from Heidelberg.

Fortunately, Herzog had a friend who was on the staff at the Heidelberg Hospital. Herzog learned that John Shannon was indeed in the hospital and seriously ill with a strange type of virus.

"They aren't sure what type of virus John has," his mother continued, "but one doctor in Austria said he could have gotten it from eating bad meat or ice cream."

Herzog offered his home to John when he leaves the hospital if he needs rest before returning home.

The Shannon's eldest daughter, Carol, an airline stewardess, flew to Germany to see her brother. "The doctors said that seeing her was the best medicine," the mother said.

Carol called her parents last night and told them John was much better. She plans to bring him home soon. It will probably be a while, however, until he returns to teaching.

Mrs. Shannon was much relieved today after the trying experience. "It seems like a small world," she said, "when people like Mr. Godfrey and Mr. Herzog will go out of their way to help you."

JOHN GORE SCHOLARSHIP AWARDED

Alan Scott WB2TCZ, of Paint Post, New York, was this year's recipient of the John Gore Memorial Scholarship. Judged to be the most scholarly and deserving of applicants nationwide, on September 23rd, Scott was awarded the $500 scholarship. John Gore was an outstanding past president of the Foundation for Amateur Radio, a group of twenty-seven radio clubs in the Washington, D.C. area.

Alan Scott is an electrical engineering student at the University of Cincinnati, has been on the Dean's list several times, and participates in a co-op program with the Naval Research and Development Center in Carderock, Md.

Information about this scholarship will be available in *73* in a few months.

Swiss Scouts In JAMBOREE

Recent participants in the Jamboree On The Air held in October.

Lele HB9AMY, in the San Gottardo, Lugano -TI- Scout Section, allows local scouts to talk with other scouts in other parts of the world.

Contest Announced

The Potomac Area VHF Society Challenge Competition consists of a contest with any club that dares to compete in the January VHF Sweepstakes. Take your club aggregate score, divide by number of members, multiply by percentage of members participating. Clubs must have six or more members and have been in existence since 1/1/71. At least fifty per cent of the members must have been in the club before 7/1/71. Honor system will be used in computing scores. Highest scoring club by this system, other than PAVHFS, will receive an engraved trophy. Any club scoring higher than contest sponsor will receive a handsome certificate. All mail handled by K3LNZ.

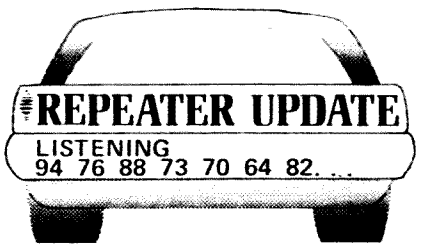
IN WORCESTER, MASSACHUSETTS:

FM SYMPOSIUM FEB. 12th

A full-fledged hassle and exposition is in the works for mid-February in the Worcester (Mass.) area. If you have any interest in FM, two meters, ham fist-fights, looks at the newest developments in ham gear, and such, you might consider braving the wintry winds of central Massachusetts and heading for a full day of enervation at the First New England FM Symposium.



The need for some sort of general conflab of the 40-plus repeater groups in New England reached the level where even 73, which has taken little note of this new-fangled flash-in-the-pan FM fad, felt constrained to follow the lead of its publishing compatriots and make a fast buck while the pickin's are thick.

The Symposium will attempt to get the 40 groups face to face in the hope that a frequency coordinating board can be named to plot the progress of repeater allocations in New England. Arguments will be heard on closed vs open repeaters, television and RTTY repeaters, touchtone vs tone burst entry and control, big vs little repeaters, repeater tie-ins, and plans will be discussed for expanding repeater operations to other bands such as 75m, 40m, 20m, 10m, 6m, and even 220 and up!

Watch the February issue of 73 for final details on place and program. The program will start at 10 am and last through until late that night. Talk-in will be through any of the dozen or so nearby repeaters or on 94 direct. Listen 19-79 WA1KGO, 37-97 WA1KRJ, 25-76 K1MNS, 34-94 K1AIU, 34-94 WA1KGR, 25-79 WA1KGZ, 22-82 W1HWK, 28-88 K1AOI, 01-64 WA1KGS, 04-91 K1FFK, 10-70 WA1KFZ, etc.

NEW FREQUENCY SYNTHESIZER IN THE WORKS

Vanguard Labs is hard at work on their frequency synthesizer for FM and you should see announcements soon for a transmitter model with output on 6, 12 and 18 MHz for two meter transceivers and hitting every 10 kHz for around $100. This one will operate over a ±10° C temperature range. André will have one for −10 to +70° C for around $150.

EDITORIAL BY WAYNE GREEN

Ten Meter FM Link

A call from W7DXX got the juices boiling for a ten meter link channel between FM repeaters around the country, or even around the world. As a result I have ordered a little ten meter FM rig which we will be setting up in conjunction with WA1KGO to send and receive on 29.68 MHz with tone access from the 19–79 two meter service.

When six meters opens up I have a great time through W1ALE in Concord, N.H., which has a 52.525 MHz function connected to its 46–94 operation. Ten should be even more fun since it opens a lot more than six does.

Say, I'll bet all those swingers down on 3999 kHz would really dig a link to that channel through your repeater! How about it? It would wake 'em up for sure. When you do it please be sure to make careful notes of the ensuing bedlam and send them to *73* for the newspages.

In the meanwhile, how about getting set up on 10m so we can have some news of mobiles in Munich talking via 2m–10m repeater to Oregon?

Expanding the Tech Band

The FCC has been sitting on several proposals to expand the Tech frequency allocations on two meters. If, for some reason which is really not too apparent, the FCC is reluctant to let the Techs use all of 2m, perhaps they would buy an expansion of the band. This could be tried if an individual or group would petition the FCC to expand the Tech privileges to, say, 144.5 through 148 MHz. This would still leave 500 kHz for the higher class licensees, which is far more than adequate for the amount of activity on the band at present . . . or that has been on the band during the last 20 years . . . or that we can envison on the band in the foreseeable future unless some development comes along which is not imagined yet.

The progress of FM would be eased with such an expansion. What do *you* think?

Ideas

The Morse Memory unit in the December issue got us to thinking, when this is used for repeater ID, all that storage capacity is not really needed . . . so why not use some of the left over IC function for a timing circuit or two? Most repeaters need a timer to permit a one to three second lag for the squelch tail and another to time the repeater off the air if a continuous signal comes in for three minutes.

And how about someone coming up with a simple LED numerical readout for FM channels which is controlled by the crystal switch? You wouldn't need a counter, just a means of coding the readout when the particular crystal is installed. It would be a lot better than just channel numbers, right? Two numbers for the transmit channel and two for the receive would do it. Well?

220 Repeaters

Little has been done with 220 FM as yet and the pattern of repeater channelization is in a state of flux. I would like to offer the pages of 73 as a forum for discussion of possible channel plans. As a starter you might consult the chart on page 100 of the April issue of 73 which listed the 220 proposed channel frequencies.

One of the deficiencies of the two meter FM development, from my point of view, was the use of the commercial scheme of using just one channel for both transmit and receive, thus enforcing the usual type of radio contact where one person at a time can talk. Duplex, where both parties can talk at once, would be more fun and, unless there are serious problems of available frequencies, would seem beneficial. So naturally I suggest that we give strong consideration to setting up 220 for duplex operation.

If we set up our repeaters on 220 spaced 3 MHz, we should be able to receive while transmitting without any serious problems. Okay for one channel. So I propose that we start at 220.02/223.02 for the first pair, and then run a duplex pair for that repeater on 220.06/223.06. In use we would transmit on 220.02 and receive on 223.06 for one pair and transmit on 220.06 and receive on 223.02 for the second pair, transmitting and receiving simultaneously for full duplex operation. If 220 repeaters proliferate anything like 146 repeaters, the crystal expense could be almost prohibitive, running double that of two meter channels. I suspect that synthesizers will be with us shortly and will provide a low-cost solution to that difficulty.

If you have any experience or educated opinions on repeater channel standards for 220 please consider this a request for your expertise.

Coming Special Issues

We are hard at work on our usual spectacular March Surplus Issue of 73. If you have any last minute surplus conversions (relatively simple ones) this is the time to send them in. And what else would you like to see in a surplus issue? Let me know. I'll try to have the biggest collection of surplus ads I can muster.

April will again be special FM Month. I would appreciate getting as many FM circuits as possible for inclusion in this issue. Please make the circuits as complete as possible so only a little text is required for them. Send in tone code, decode, COR, PL, touchtone, control, timers, identifiers, logging devices, antennas, or whatever you think you might have that others would like to know about and have not seen. I'll have a complete crystal selection chart for all commercial rigs in the issue. And I'll try and bring you a complete rundown on all available FM ham transceivers, amplifiers, and such.

Beyond April we are working hard on special features in later issues on portable and mobile equipment, antennas and towers, VHF/UHF, DX, IC/solid state . . . and plenty etc.

FM Expansion Proposal

The FM channels between 146–147 MHz are pretty well occupied in the New England area and are filling up rapidly in several other population centers. The question that arises is where next?

Since there is no FCC regulation prohibiting the repeating of a Tech licensee into a higher class license segment of the bands providing the licensee of the repeater is appropriately licensed, the expansion of repeater outputs into the 147 MHz range is possible. But where do we put the input?

In practical application, most of the AM and other non-FM activity on two meters occupies the lower half MHz of the 144 and 145 MHz segments of the band. It seems to me that it would be practical for FM repeaters to start using the other half MHz bands, with their input from the 145.5 to 146.0 band and output in the 144.5–145.0 band, separated exactly 1 MHz. Remember that the 600 kHz separation used in the 146 MHz band was a compromise for operators who wanted to transmit on both input and output frequencies (146.34 and 146.94) without having to retune their rig. If you can give up the need

to use the repeater output as a simplex channel you are freed from the 600 kHz restriction.

If we had it all to do over I just wonder if we might not opt for an even wider spacing between input and output so full duplex would be possible? A 2 MHz spacing would permit this and enable us to indulge in a completely different type of contact. Well, I guess it is too late to cry over spilt milk on two meters, but we certainly should keep this lesson in mind when we start populating 220.

What do *you* think?

Proposed FM Repeater Channels

FM News

C. T. Power, who makes the Tempo amplifiers being marketed by Henry, will be out shortly with a little FM two meter amplifier for under $100 (namely $99.50) which will take the average 10 watt transmitter and boost it to 40 watts out. This should be a popular item since an extra 6 dB from most mobile rigs could extend the range substantially. Their 220 transceiver, announced recently, is seriously back ordered, proving that a U.S. made 220 transceiver at $180 was definitely needed. Their repeater version of the rig should be along soon and we're going to do everything we can to encourage every repeater group in the country to add a 220 MHz repeater to their present setup in the hope that a quick population explosion in that band might tilt the table in our favor when it comes to consideration of the dreaded EIA proposal to carve up that band for the CBers.

As if all that weren't enough, C. T. Power is also hard at work on a 450 MHz transceiver. They already have a beauty of a solid state 450 amplifier which turns 4 watts into 30 watts and sells for $210. If they can keep up with the commercial demand for that one perhaps we will be seeing some on our 450 repeaters. They also have a two meter transceiver and a repeater package well along. The transceiver will have 11 channels plus a vfo and is planned to sell for about $255! 15 watts. The repeater will have its own 12 volt supply and use a car battery in case commercial power is interrupted, with its power supply keeping the battery in full charge.

GATHERINGS

Wheaton Community Radio Amateurs (WCRA) will hold its tenth annual Mid-Winter Swap and Shop on Sunday, Feb. 20 at DuPage County Fair Grounds, Wheaton, Ill.; 8:00 a.m.–5:00 p.m. $1 advance, $1.50 at door. Refreshments and parking. SASE to WCRA, P.O. Box QSL, Wheaton IL 60187 for info.

California

Southern California DX Club plays host to the 23rd annual California DX Conference on January 22 and 23 at the Del Webb Towne House in Fresno. Beginning and experienced DXers are invited to attend. Speakers include 3CØAN, ZA5C, VK9NP, and 3B9DK. Talk, cocktail party, steak dinner, DX breakfast on Sunday are some of the events of the conference. Signal/One CX7A pre-registration prize. Send check for $14.50 to SCDXC Treas. Jack Hollander WB6UDC, 13531 Malena Dr., Tustin CA 92680. Include SASE. Pre-registration ends Jan. 7.

Indiana

The Lake County ARC's nineteenth annual banquet on February 12 will be held at a different location this year. It will be at the Scherwood Club in Schereville, Indiana. Map is on back of the five dollar tickets which can be obtained from Herb Brier W9EGQ, Ticket Chairman, 385 Johnson St., Gary IN 46402, or from other members. No tickets at door.

Arkansas QSO Party

From 2200z Sat. Jan 22 to 0400z Mon. Jan 24. Ark stations score 1 pt per contact times number of States, Provinces and countries worked. Non-Ark stations 5 pts per Ark contact. Stations may be worked once on each band and with each mode. Certificates for highest scorer in each State, Province and foreign country with 100 pts or more. Exchange QSO number and signal report plus State or country. Suggested freqs are 3560, 7060, 14060, 21060, 28060, 3960, 7260, 14300, 21360, 28560; 3735, 7175, 21110. Logs before Feb 21 to North Arkansas Amateur Radio Society, Rt. 1, Green Forest, AR 72638.

Contests

Second World SSTV Contest, sponsored by *cq elettronica magazine*. This contest is to promote increased interest in SSTV as used by radio amateurs. Contest period is Feb. 5, 1972, 1500–2200Z, and Feb. 13, 0700–1400Z. All bands may be used, and the exchange is picture and number of the message.

Two-way contacts score one point (total points is number of individual stations contacted), no extra points for contacting same station on different bands. There is a multiplier of 10 points per continent and 5 points per country (ARRL list). Score is computed by multiplying exchange points times multipliers. All logs to be submitted must contain date, time (GMT), band, call, message numbers sent and received, and points.

Send logs to Prof. Franco Fanti, via A. Dallolio 19, 40139, Bologna, Italy. First prize is a year's subscription to *cq ellettronica*; second and third prizes are 6 month subscriptions. There is a special SWL prize.

The Milliwatt: National Journal of QRPP once again will sponsor a QRPP NET for 1971-72, commencing operation on November 15, 1971. The QRPP NET will utilize the QRP ARC I calling frequencies of 7040 kHz and 14065 kHz. Regular NET times are: 7040 kHz – 0830 EST Wednesday; 14065 kHz – 1100 EST Saturday and 1800 EST Sunday. Procedure: check-ins will call CQ QRPP NET and make contacts individually; there will be no regular NCS, as we will allow conditions and activity to determine operation of the NET. In addition to the regular NET times, stations are requested to monitor the NET frequencies for possible calls at the following times: 7040 kHz – Sunday, Monday and Wednesday at 2100, 2200, and 2300 EST; 14065 – Sunday, Tuesday, and Thursday at 0900 and 1845 EST. Monitoring stations are requested to tune ±2 kHz, and should be reminded that calling stations, running at the milliwatt power level, will probably be weak, and hence rf gains should be turned up. We request stations making contact on the NET to report them to *The Milliwatt* c/o Adrian Weiss, 117 Central St. #F-10, Acton MA 01720.

Also, *The Milliwatt* sponsors two awards for QRP DX operation. One is for low power contact with twenty-five or more countries, and the other is for very low power (under 1W) contacts. For full details, contact Adrian Weiss at the above address and include a SASE, or check a copy of *The Milliwatt*.

Guest Editorial

Wells Chapin W8GI

The introduction to the fiftieth anniversary publication of the Institute of Radio Engineers proceedings started thusly: "The life of a man or organization has been aptly compared to the sequence of lights and shades during one day on earth. In the early morning, long shadows lie to the West as the sun rises. Then these shadows shorten as the day advances until no shadows are visible in the noonday blaze of light. And later, the shadows lengthen as the sunlight wanes, and twilight and night approach."

These words were written during a critical period of the life of two very fine professional organizations, the Institute of Radio Engineers (IRE) and the American Institute of Electrical Engineers (AIEE). Both organizations were facing real problems and both competed in many instances for the same men. The managers of these groups – being professional men – recognized the dynamic changes swarming around them and planned ahead. They could see that both groups were headed for trouble unless something was done. They acted, merged, and formed the present Institute of Electrical Electronics Engineers (IEEE), which is now a very fine, respected and prosperous organization.

Herein lies a parallel – the ARRL is in the shadows of the afternoon and faces the darkness of the night, and the same type of problems that the IRE AIEE faced. It is amazing to look at the parallels. In amateur radio we have CW vs phone, DX vs ragchewers, traffic men vs non-traffic men, one band vs the other, one modulation vs the other, miscellaneous organizations and their separate goals, ad infinitum. Yet all these men are amateurs and should be brothers. Just as the IRE and AIEE did, the ARRL faces many of the same type of problems, including financial difficulties. So what do we do about it?

It is interesting to compare the problems of IRE and AIEE to those of the League and at the same time look at the different approach to their solution. First of all, the IRE put their problems on the table. They were freely admitted and written up in the Proceedings, both pro and con. The Proceedings did a magnificent job of defining the problem, presenting both sides. They did a real management job and followed this up with action and a factual reporting job. When a merger was suggested, they presented the pros and cons and sold the idea. That is why the IEEE is a solid, respected organization. They knew how to keep their members happy; they calmed dissention through the printed word. Why not take a serious look at the IEEE and take advantage of their experience in successfully solving the same sort of problems we amateurs face.

The IEEE now has two magazines for its members. One is very technical, the other is more broad brush and appeals to those who do not care for the highly technical. They have 34 technical groups, each with a different interest, and each have local chapter meetings. Each group has a small paper-type of publication for its members which covers their particular interests. The IEEE has regional and local chapters. According to a 1970 article in their *Spectrum* magazine, the IEEE has 169,059 members, not unlike that of the League numbers or at least what the League numbers should be. They have different classes of memberships, including Fellow Senior Members, Members, and Student Members.

The roster of the IEEE has thousands of amateurs. One famous, highly respected name that appears in the roster is that of our former ARRL president, Mr. George Bailey. In the past the ARRL has had some wonderful, highly respected, very competent men as president – for instance, Herbert Hoover, Jr. Now let's ask why these men resigned the presidency of the ARRL? All you have to do is read the Constitution and by-laws to find the answer. As you read, you find that the president is for all intents and purposes, powerless to act. Therein lies a basic problem. Therefore let's take a look at our antiquated Constitution and by-laws and bring them in tune with the times and give our president some real authority and responsibility. Let's have a paid president who works at the job. Other sections of the Constitution eliminate some real talent, because they prohibit a person to be a director who has an interest in manufacturing of electronic equipment, or a person associated with a radio magazine. There are other sections just as unwieldy and outmoded as these. How about a committee to report on bringing our Constitution and by-laws in tune with the times?

Let's look at a name change to better reflect the purpose we have of selling amateur radio. Then pattern local chapters of amateur radio groups just like the IEEE. For instance, why not call our League the Institute of Amateur Radio, and then instead of a flock of clubs with various names and aims we could have, for instance, the Detroit Chapter of the Institute of Amateur Radio, and under that subhead have the Detroit DX group of the IOAR, the Two Meter group and FM, the CW group, and so forth, and then have Michigan Regional State groups. Here in Detroit we have a social occasion each year for the regional IEEE members. Why not envision all amateur radio groups under one name? A name projects one's aim or purpose. Who knows what the ARRL means but an ARRL member? Let's get public relations conscious and organization conscious. Look at the power of the auto workers and the various other unions. In union there is strength!

Now let's take at look at the League. Only one side of the story appears in QST and that is highly biased. You never read what a director stands for. Even our directors cannot get the other side of the picture printed. Why can't the ARRL lay the problems on the table and then solve them and sell the solution to all – repeat, all – amateurs and not just League members, and at the same time show the importance of all amateurs belonging to the League. It just is not healthy to have dissension in the ranks of the ARRL dividing the approximately 80,000 members. At the same time, we tell 200,000 other non-member amateurs what is good for them, and we supposedly represent their views in the League presentations to the FCC, when in fact they haven't been represented at all and what's worse – they don't know what is going on because they don't get QST and don't even have the chance to read the biased views presented.

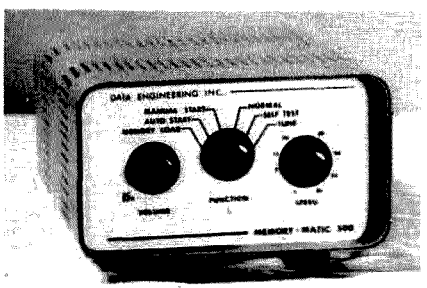
Why do we resist change? Those who resist change generally suffer the consequences. While we are sitting around operating as we did fifty years ago, a communications revolution, population explosion, and dramatic world changes are swarming around us. The ARRL seems to doggedly resist change, and in addition sweeps the problems under the carpet when they should be laid out to view. We should ask the help of some of our very competent amateurs who are not League members in solving our problems. Read the *Who's Who of Amateur Radio* and you will find thousands of names that would add prestige to our organization in addition to bringing real talent to revitalize the League.

What ideas do you have? Write your director, demand action, and send a copy to *73*. Let's revitalize amateur radio and make it the healthy, respected entity it used to be.

. . .W8GI

Mr. Chapin has some interesting constructive ideas regarding the League which need airing. 73 welcomes such comments from any reader, pro or con the League and any other matter of vital interest to all amateurs.

NEW PRODUCTS

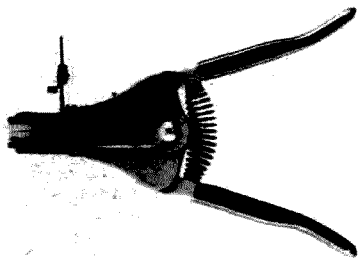


CW KEYER and MORSE MEMORY UNITS

Data Engineering Inc. has come out with a pair of keyers that may just revolutionize the whole keyer field.

The Space-Matic 21 keyer is designed to work with any key or paddle, but in particular with the Data Engineering solid state electronic key. When both dot and dash paddles are touched the keyer alternates dots and dashes. The spacing between dots, dashes, characters and words are automatic and fixed in length, assuring the most beautiful CW you've ever sent.

The keyer has sidetone built in and a reed relay to key the transmitter.



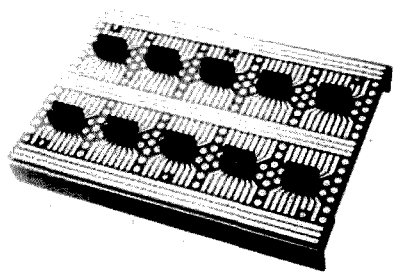
The Memory-Matic 500 has all of the same features of the above plus a 500 bit memory which will handle about 50 characters. Imagine what a difference this can make in a contest! You can put in the signal report, section and date to be sent to each contact automatically, so all you have to add is the call and time by hand and you are on to the next contact.

Two meter repeater owners may like using this for identification, as may remote base users on the VHF and UHF bands.

When you are loading the memory with a CQ call or a contest exchange, a side tone lets you know when the memory is near full by rising in pitch. A steady tone indicates it is full. The message in the memory can be sent back at any time at any speed from 3.5 to 85 wpm. Will we be hearing even sideband stations being identified every ten minutes with a short burst of weak tone from these memories? Will RTTY operators flip one of these in to give the CW identification required?

Prices are very reasonable for these two devices. The Space-Matic 21 keyer is $89.50 and the Memory-Matic 500 is $198.50. Write to *Data Engineering Inc., Box 1245, Springfield VA 22151* for specification sheets.

Automatic Wire Stripper and Cutter



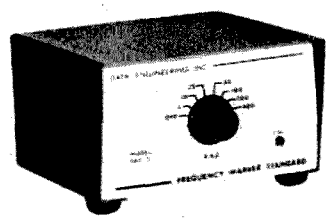
Radio Shack is offering a new Automatic Wire Stripper and Cutter in their line of Archer tools which they say strips #24 to #12 gauge wire perfectly in a second.

To operate the wire stripper you simply insert the wire, squeeze the insulated handles and release. Insulation is removed cleanly and completely without nicking or breaking wire. A strip gauge guides the wire to the correct portion of the blade and assures a uniform stripped length every time.

The Archer Automatic Wire Stripper and Cutter is priced at $4.95.

Archer tools and accessories are available exclusively through Radio Shack's more than 1100 stores in 49 states and Canada, or by mail.

PROTOTYPE BOARDS



Experimenters, rejoice! Maratron *(Box 777, Dallas TX 75221)* has come up with just what you are looking for. Prototyping boards designed for transistor and IC circuits. They have patterns for 4 lead transistors, DIP IC's, and TO-5 IC's of 8 and 10 leads. Dot patterns available for using discrete components, too. And all boards are reusable. Write and say 73 sent you.

Security Catalog

Amateurs interested in working up a nice little second income could do a lot worse than getting into the security business. There are few offices or stores, or even homes for that matter, where some security system might not be needed. Wouldn't your wife sleep better if your home were protected against intrusion and fire? One of the big problems for anyone wishing to get into this fast-growing field has been one of getting information as to available equipment. *The Mountain West Alarm Supply Co., 4215 North 16th Street, Phoenix AZ 85016* has a free catalog (64 pages) of the latest security gadgets and, armed with this book, you can go into business for yourself. Please mention 73 when you send for that catalog, okay? And please remember where you got the idea to do this when you are rich. Don't be a fair weather friend.

FREQUENCY MARKER DELUXE

100 kHz markers have been around for a long time, but they are inadequate to meet the demands for band edge marking and calibration with today's split up ham bands. How many operators know for sure exactly where the 3825 band edge really is? Or 14275?

Large scale integrated circuits make a low cost (relatively) frequency marker possible today which starts at 400 kHz, splits that to 200 kHz, 100 kHz, 50 . . . 25 . . . 10 . . . and even 5 kHz! Data Engineering Inc. has announced just such a unit and is marketing it for $32.95 complete with built-in battery holder and a five year guarantee. The marker, less cabinet and stuff is available wired, tested and calibrated for $22.95 . . . or even in kit form for a lowly $19.95. It runs from four penlight cells. The uncabineted one should be fine to build into your receiver if you can figure where to borrow a few mils of 6 volts. The square wave output of the marker rings out clearly even above 150 MHz, so it can be used for zeroing in those FM crystals. The calibrate screw driver control on the front panel is for touching it up against WWV.

Spec sheets are available from *Data Engineering, Box 1245, Springfield VA 22151.*

NEW TONE BURST ENCODERS ARE DIRECT POWERED

The Ross and White Company has announced two new Tone Burst Encoders that are powered directly from FM, 2 meter transceiver power sources in transmitting repeater access signals.

Keyed by closing the transmitter microphone switch from the 12 volt dc keyed source, the Encoder generates a half second tone burst which modulates the transceiver and automatically activates the tone allowing activation of tone access.

Two models are available. The two tone model TE-2 sells for $39.95 and the five tone model sells for $49.95 postage paid. Both are sold on a 10 day trial, money back guarantee basis.

Installation of the TE-2 and TE-5 is relatively simple using the complete instructions provided for your make and model of transceiver. The battery powered models will continue to be available for hams preferring that arrangement.

For full data including specifications, write direct to the *Ross and White Company, 50 West Dundee Road, Wheeling IL 60090.*

Motorola's HEP Introduces LEDs

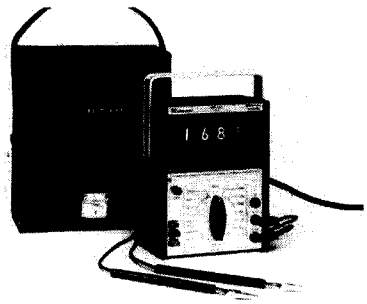
Light emitting diodes are now available to the hobbyist-experimenter through Motorola's HEP semiconductor line, with the introduction of four new light-emitting diodes, three visible red and one infrared device (P2000, P2001, P2003 and P2002). These devices are ideal for digital clocks, frequency counters burglar alrms, panel lights and on/off indicators. The devices are available now at authorized HEP suppliers nationwide.

NEW 2M FM TRANSCEIVER

A built-in tone burst encoder is featured in the new Ross and White 2 meter FM transceiver Model RW-Bnd now available from the Ross & White Co., Electronics, 50 West Dundee Rd., Wheeling IL 60090. The built-in tone burst encoder provides quick and easy access into tone activated repeaters now becoming common across the country. Three tone selections are provided. All tones are factory preset to commonly used frequencies but can be easily reset.

A front panel power selector switch lets you choose power output for 0.1, 1.0, and 10W. Another switch allows 12 channel capability. For those who do not wish the tone burst function, the rig is available without it, and the encoder may be added later as an accessory. The RW-Bnd comes with mike, mounting bracket, and four channel combinations installed.

MEMORY IC'S



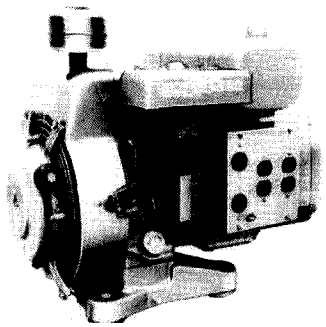
Repeater control and CW keyers with pre-recorded message circuits are advised to investigate Intel Corp.'s sixty-four bit memory and binary decoder IC's. These are random access or addressable memories. Series 3101-3104 memory and 3205/3404 decoders; info via *Intel, 3065 Bowers Ave., Santa Clara CA 95051.*

NEW SWL RECEIVER

Heath of Benton Harbor has come up with a new SWL receiver, the SW-717. It covers BC through 30 MHz, has a built-in speaker, and tunable bfo to copy CW or SSB. It looks good for the Novice or as a second receiver for the occasional SWL in all of us. Write to *Heath* in *Benton Harbor MI 49022.*

DIGITAL MULTIMETER

Triplett, after all these years of being first in the meter biz, has come out with a digital v-o-m! Billed as a 2¾ digit meter, the last figure tells you whether the number is above or below five. The price is 2¾ centibucks, which makes it a little high for the average ham shack and probably of more interest for lab or service shop use where the time saved by using this meter could eventually pay for it. *Triplett, Bluffton OH 45817* will be delighted to tell you all about it and ecstatic if you buy a few dozen.



1W FM TRANSMITTER

Avcom has come out with just the thing for those who want to go FM but cannot afford to. The FM-201 is a miniature 1W transmitter that can be mounted inside any of the high-band monitor receivers to make an instant transceiver for under $200. Or if walkie-talkie is your bag, any of the portable high-band receivers and this rig will make a hand-held unit for under $100. Multi-channel operation is possible; and with the 10W power amplifier, a handy walkie and mobile combination is easily within the reach of most hams' finances. Contact *Avcom at P.O. Box 29153, Columbus OH 43229.*

RECTIFIER INFORMATION

Hams working in RTTY, FM, and those experimenting with logic may find a new Motorola silicon controlled rectifier useful in low power switching, detection and sensing, and control functions. These units draw very little current from the circuit and are less than one tenth inch in diameter. Write to the *Technical Information Center, Motorola, Inc., Semiconductor Products Div., Box 20924, Phoenix AZ 85036* and ask for info on their Micro-T MCR051 through 054 series.

3 kW Generator

A new air-cooled, 3 kW gasoline–driven electric generating set was announced by the Onan Corporation.

Available in both manual start and remote start models, the new model 3.0NB provides 3 kW of 120/240V, 60 Hz, single-phase, 4-wire electric power at 1800 rpm. All models are reconnectible to deliver rated output at three different voltages 120V, 2-wire; 240V, 2-wire, or 120/240V, 3-wire – permitting the user to employ equipment of different voltage requirements through a simple wiring change.

An important feature of Onan's new Model 3.0NB is the single-manufacturer construction throughout. The air-cooled engine, revolving armature generator and (when used as a standby unit) the matching automatic load transfer control are all designed, built and tested by Onan to operate together as a single-integrated system. *Onan Division of Onan Corporation, 1400 73rd Avenue, N.E., Minneapolis MN 55432.*

What with the emphasis on upgrading one's license due to incentive licensing structure, it behooves the amateur to learn, not memorize, his electrical theory. When test time comes and the Man is staring at you and the temperature in the room creeps to 120°, your memory can fail,but not if you really know what you are talking about. You can read books or attend classes, but there is a lot to be said for practical experience, too.

One way to get this experience is to operate your station, but twisting knobs and watching meters bob around only goes so far. If you want to know how to operate your rig, read the instruction manual which should have come with it. If you want to know how your rig operates, read the instruction manual section entitled "Theory of Operation." It's easy to quickly read a few paragraphs, but try this way instead. It will take longer, but it is better for anyone who wants to learn.

Disconnect the rig and open it up, but leave the ground wire connected. Use all safety precautions. Now with the manual in front of you, read the section slowly and where it says plate tank coil, find it in the rig and touch it. Examine how it is placed. Is it parallel to any other coils, or perpendicular? Is it shielded or in the open? Notice parts placement in the rig and also how they are placed on the schematic. To become familiar with these pictures will make the FCC tests easier and also you will be able to read any of the amateur magazines with greater enjoyment. Also look for the different components mentioned in the theory section of the manual. If C6 is a bypass capacitor, what is it bypassing? What is bypassing? Why bypass at all? Any terms that are unfamiliar or vague should be looked up in a handbook or other references. Even after looking at your own rig a few times and perhaps a few others, and then reading the pages of this or other magazines, you might recognize a section of the schematic. It may be an oscillator stage, or an i-f. In time, the different sections become connected in your mind and you will know what the author has in mind. Of course, you should read his comments about the theory of operation of his unit, also.

For many – Novices and Generals alike – this can open a whole new dimension in our hobby. An awareness of what takes place behind the brushed aluminum panel is valuable not only for assistance in passing the next higher ticket, but it adds enjoyment and comprehension of the journals. Never overlook construction articles or articles of electrical theory. These are what the hobby is made of. As you become more familiar with the theory, you might want to try a small construction project. Nothing fancy, perhaps a field strength meter (meter, diode, and a choke). When it turns out right, the next project might be a little more complicated, like a one transistor code practice oscillator. Maybe you can even design one yourself. Then maybe a small QRP transmitter. Speaking for myself, I was a ham for over ten years and never built more than two kits. Then, about a year ago, I built an antenna. Then a CPO and monitor. Then a field strength meter. Then a QRP transmitter. There really is nothing that can compare with the feeling of satisfaction that comes from communicating with someone on a rig that you built yourself. It is a warm glow that spreads up from the gut to a dizzy sensation in the head. It happened to me on my first QSO with a 100 mW transmitter. I'm getting the bug to build and I know what I'm building, and why it works.

When you face the examiner the next time, you'll walk in with confidence, knowing you have the knowledge at your fingertips. After all, you've been working with this material for some time and you have made electronics a part of your life, not just another pastime.

I have finally given in to my carnal desires and am begging for a chance to read 30 untouched issues of 73. I had to decide whether I wanted the Gunsmoke or the Extra Class Study Guide. I guess I like fun more than work. Seriously, I used the Advanced Class Study Guide and passed with only a week of study. This fact did not change my views on the horrible nightmare of incentive licensing, however.

As I now have a new call, W7INH, I feel like an old timer and can now give out my opinions with the rest of them. WB9FIN in the Oct. issue mentioned only a few of the rotten acts which take place on 20 meters. I used to think 40 AM in the early sixties was mayhem. I cannot even speculate why hams' manners have deteriorated so much lately. I could not afford SSB equipment and was inactive until recently and the change in operating habits is startling, to say the least.

Everyone seems to promote their own interests these days, so I have a few proposals':

1. I cannot afford a tower or a beam as I am now paying back all my law school debts so all beams and quads should be outlawed.
2. My transceiver only runs 200 watts PEP so that should be the power limit.
3. I did not notice the code "hump" of ten words per minute but I am rusty now so the 20 wpm requirement for the Extra must go.
4. I am too dumb and too busy to homebrew my equipment so all questions on the exams concerning theory except those on antennas and feed lines should be removed. (For some reason I understand SWR.)
5. As I just finished three years of law school, most questions on the exam should be from pertinent FCC and international regulations. I think I could pass the Extra exam and be on someone's honor roll if this were done.

Steve Guelde W7INH ex K8RSX
Cheyenne WY

As a professional language educator, I want to congratulate Gilbert Ford on his excellent article, "Say Coo, Say Coo, Day Eckees." (September, Page 107). It is well written, good content-wise, and – hopefully – useful. May I, too, encourage amateurs to try even a few words of another language. It pays handsomely in friendship if you'll just try.

Philip D. Smith W3DZR
West Chester State College PA

This is a comment and suggestion about your proposed "handbook" format. It is basically an exellent idea. It seems to me that many advertisements are almost useless. They say someone is selling such and such, give a price and address and perhaps a sales pitch. On the other hand I suspect most hams and experimenters have some difficulty obtaining technical data on components. Do you suppose that the component manufacturers or suppliers could be persuaded to devote some of their advertising space to data sheet type stuff. For example, the ad in the October issue listing a bunch of semiconductors is useful to someone shopping around for the cheapest price on,

Continued on page 10

LETTERS CONT.

say, a FET for a VHF front end, but I would rather see, and might sooner be tempted to buy, an ad with data on a single device or family, with prices and an address at the end.

Bill Rutiser
Brandywine MD

Good idea!

DEPARTMENT OF AMPLIFICATION

I want to thank you for the nice write-up you did on our alarm. One thing you didn't mention in the article which is important, is that our system (when used with your car's horn) causes the horn to pulsate in a "beep-beep-beep" fashion so that it cannot be mistaken for a stuck horn. It may seem like a small detail, but we feel it's a very important one.

Walter Scudder Jr.
Technical Product Development. Co.
Nutley NJ.

I just finished reading Gilbert Ford's article in the November issue, "Let's Revise the Morse Code." He makes a very good case, but we all know it will never happen. However, some rather interesting conclusions can be drawn from Figures 2 and 3 (bit length of letters and frequency of occurrence). Just nine letters (E-T-I-A-N-S-R-D-H) constitute 65% of all letters used according to the "frequency of occurrence" (Fig.3). These same letters have a bit length of 10 or less. Mr. Ford makes the valid point that the "momentary speed burst effect' is the ultimate limiting factor in anyone's ability to copy code. Any ham who can copy 13 wpm already has the ability to copy these nine letters at better than 20 wpm. It seems reasonable that every ham could copy over 20 wpm by concentrating practice on these nine letters until he could copy these at an average speed of 35 to 40 wpm.

Now, if we could get our friends at Newington to include 15 minutes of E-T-I-A-N-S-R-D-H at 40 wpm as a standard part of daily code practice we would soon all have "Extra" class licenses and the need for confusing "sub bands" would vanish!

Robert B. Baker WA7NCT
Billings MT

That Heathkit 15 MHz counter took me 5 hours at the most, and worked first time. Now my pupils won't believe any other kind of frequency meter. I'm not an experienced assembler – I'm a Physics teacher; I pick up the iron when I feel in need of therapy.

Bill Jarvis GM8APX, GM6AGF/T
Dall School
Perthshire, Scotland

Re the Washington tower case, page 5 October issue, I have sent along a modest amount to help in the case. It is important to all of us to cooperate in these tower cases as they arise, in order to establish as many favorable legal precedents as possible. They will be needed in the future, as public opinion against towers and poles increases. The power and telephone companies are already under increasing pressure to put their distribution lines underground. It is anticipated that cable TV will, in the near future, expand very rapidly, mostly because of the extended service it offers – 20 channels are quite likely. In time, as sets and antennas wear out, people will switch to cable TV. Eventually, the forests of TV antennas will disappear, and the pressure against the ham antenna will mount even more. (On the plus side, hopefully, the TVI problem will be eased.) Looking into the distant future, and barring catastrophe such as nuclear war, the TV frequencies will be commandeered for mobile use. Probably all non-mobile radio uses will be banned. But by that time, the hams' spectrum space will long since have been eroded.

John P. Kinzer KV4FY
Christiansted, St. Croix, USVI 00820

Thought you might be interested to know that my article, "Amateur Radio and the Handicapped," in the November issue was very well received.

I received personal letters from other disabled and non-disabled hams in California, Minnesota, and Arkansas and many comments from local amateurs.

It is not too often that articles like this or information for disabled operators appears in magazines like 73. I wonder how many amateurs know of the Handi-Ham System in Minnesota where amateur equipment is loaned free to those who need it, or the Handicap Net? How much of the transistorized and IC logic can be used for the blind, deaf, and physically disabled? There could be many interesting and quite worthwhile articles written in this area.

Ron Perry WA2CGA
Trustee W3CVT

Having just read the plight of WN30SI in November Letters section, I decided I'd better not take *any* chances. Renew my subscription, take my money, and leave me in peace. (Could you get word to the Subscription Department about returning the rest of my family and my receiver, please?)

All kidding aside, I really enjoy 73. I just hate to see you dump it on some unsuspecting person. From where I sit, the reason 73 is successful (and it is) is that none of the people connected with 73 have lost the "common touch." Congratulations on that and the best of luck in your new endeavors.

James Morrison WN9FRP
Geneva IL.

Rather than to fight non-business CB over 220 MHz, a much more practical solution is to establish a "Communicator" class ham – no test, or modest test, crystal control on assigned frequency, modest power, transmitter adjustment by other class ham or 2nd Phone. Rather than to open a Pandora's Box – to my mind it will stimulate other class ham growth, provide commercial incentives now lacking on 220, stimulate observance of radio regulation rather than to make the citizen a criminal as is now the case by multitudinous regulations, low power, and skip band temptation – certainly a hot potato for the FCC – with neither enough manpower or money to enforce the regulations.

We as hams need more of us when it comes to international frequency conventions, e.g. 1 or 2 million rather than ¼ million to provide public service in time of trouble or disaster.

John K. Lassig W5IOV
Houston TX.

I just received my long awaited November issue of 73, but, alas!! What happened to the mobile theft alarm mentioned under "FM" on the cover? Did I not read the fine print?

John H. Bauer W4AWM
Arlington VA.

Someone stole it.

Sorry to have neglected to renew my subscription. Certainly would not want to be without 73, it's tops. At my age (75) discretion may be the better part of valor, so a 1 year renewal will suffice. Have been hamming since 1911 and still enjoying it immensely with the help of 73. Long may it wave.

Edward J. Gallagher WIDD
Quincy MA.

FM PRO AND CON

I have received your information that my 73 magazine subscription ran out. Thanks. I received all issues and thanks on that. You run too much on your pet FM, FM Repeaters, and that cuss hog talk junk. You call it sideband. I would not have any of such junk in my shack. Only two issues of 73 had any ham dope on AM.

When you publish a lot of AM Trans. construction then I will sure subscribe.

Geo. Ball 9BFU
Omaha NB

I know you want to retire, but I must say it is a great relief to have you back at the helm of 73 once again. Now perhaps we can get out of the FM rut. Not that I'm not interested in FM, but too much of one thing bores me to death. I'm confident that 73 will continue to receive periodic renewal checks from this QTH. Although one of your subscribers from issue #1, I must say I nearly jumped ship this year.

Hopefully your annual surplus issue will once again have articles about surplus in it! Hopefully they will be written by those superstars of 73 such as Roy Pafenberg and LeRoy May. Ah, those were the good old days . . articles about RTTY, SSB, CW, antennas, new fangled domaflotchies and old circuits . . . and an occasional article about FM. Bring 'em back, Wayne.

Kenneth D. Grimm K5KBH/4
Sweet Briar VA

FM? What is that?

In regard to WA1LOT letter in Nov. 1971 issue let me say I agree with him fully. I would like to see a little less FM – more Bob Manning – and more YL candid shots.

Greg Bodker WN8IZM

While we have had hundreds upon hundreds of letters from readers who are having the time of their life as a result of reading about it in 73, we have yet to get a letter from anyone who has said we mislead them about the fun to be had on FM. We're with you on more Manning and more girls . . . heh, heh.

I wrote the article appearing on page 63 of the November issue of 73. Several persons have asked me, on the air, about a deletion on page 65 of the article. You might want to add an addenda in a future issue to the effect that on page 65 of Nov. issue, on the 7th line down from the top of the right colum, the addition of: *5 percent* to the right of the plus/minus sign.

The line should read, *"May 1968 QST but I found that a ±5%"*

Jim Talens K3MNJ
Philadelphia PA

Some time ago I promised a group of people that I would put together some information on a series of very economical decade counting/display modules. I didn't get the job done until quite recently, and by now the IC price war has made most of the information obsolete. I went ahead and printed the stuff anyway, partly just to make good on an old promise and partly because there may be some residual value for general education even if the circuits are now uneconomical to build.

As you are in that business, you will know it was no more expensive, once the printer was tooled up, to produce 1000 copies rather than the few I needed, and the net result is that I am swamped with excess copies of this publication, grandiosely entitled *Application Note #1*

If any of your readers would like a copy for whatever use they can make of it – I'm ready to send out copies upon receipt of a (preferably large) SASE. It seems necessary to ask that any respondents refer to this letter so I'll be sure to know what they want . . . every now and then I get a SASE with no indication of just what it is that the sender would like stuffed in.

T. R. Jackson W1DMU
Box 1, Corinth VT 05039

Looks good, TR, better print another thousand.

It is amazing to see that a manufacturer has come out with a rig for 220 to 225 MHz. Some 15 years ago I wrote to various companies who made VHF gear if they might build a rig for this band. They all said there was no demand for them. I say there's no more demand now either. Who the hell do they think they're kidding.

This only to make it easy for citizen banders if and when FCC approves or disapproves.

I know that you along with your enemy CQ are strictly for CB and a traitor to amateur radio. The subscription I get of 73 magazine, I received as a gift. I damned sure would not pay for it, or CQ magazine. QST is for amateurs and ARRL represents us. We would never have lost 11 meters except for you traitors.

M. Schreck Jr.
Kearny NJ

The unparalleled success of 2m FM has increased amateur interest in 220 tremendously and the use of that band is being held back only by the scarcity of equipment available. The recently announced C.T. Power transceiver for 220 at only $180 has started thousands of amateurs to thinking seriously about this band. Their upcoming repeater for that band could well be installed by many or even most of the 2m repeater groups, thereby providing countrywide 220 communication.

Your faith in ARRL is touching. But who, exactly, did put up a battle to save 11m? Was it ARRL? Or was it Wayne Green, then editor of CQ? Please do go to the trouble to ask any old timer who was there . . . anyone. Now, about CB, I can understand why CQ might be pushing for CB since their S-9 CB magazine is the keystone of their publishing empire, but what explains any interest in CB on my part?

The EIA 220 proposal (see March 73 for complete details) is extremely well financed and could easily go through, thus permanently taking away a good part of our band. My proposal seems like a good compromise and gives us an alternative. Remember that EIA has a strong Washington LOBBY and amateur radio has NO Washington lobby at all.

I note in your last issue that you have been getting a bit of backlash on the amount of FM info you have been running. I am not particularly interested in FM as yet but I rather enjoy reading up on what the gang is doing on a new facet of ham radio. At least it makes more interesting reading than "Station Activities" in QST!

Speaking of new facets of ham radio, I saw some *color pictures* that Bill DeWitt W2DD had sent and received by slow scan TV on 14mc. He used a field sequential system much like the old CBS system with six frames of each color. A story like that ought to jar some of the boys who figure that the state of the art has gotten away past the average ham.

Edson B. Snow W2UN
Rochester NY

Thank you, *thank you* for returning the 73 newspages to the horizontal where they can be read without tearing the magazine apart and incurring serious migraine. Usually interesting material was becoming quite a chore to read. As an inveterate article filer, I also appreciate your new system of beginning articles on a right-hand page – please continue.

Louise Frankenberg WA3LEQ
Pasadena MD.

I will probably be going to the University of North Carolina at Chapel Hill. Please print a request for me in the letters column for a ham to room with on campus. Thanks very much and keep up the good work.

Donald Lee Curtis WN4TMU
22 Craven St.
Asheville NC 28006

Thanks for the reader service and the large, easy-to-read print. Incidentally you discontinued the "sideways" printing just in time to restore my sanity and lower my blood pressure. I don't like C.Q. and QST print is too small, so I'm depending on 73.

Arthur Ideker W5CAM
Pine Bluff AR.

How about a complete Novice station – maybe in several 73 articles or perhaps a small booklet to follow the Study Guide? Have been building QST's QRP Rig myself, but wouldn't it be fun to build something in a complete package aimed directly at the young Novice? Maybe something that could be used as a club project. I'd be the first.

D. K. Howard
155 Crescent St.
East Bridgewater MA 02333

Let's hear from some builders about this. A club project is a great way to involve Novices.

How come you had nothing on the story behind the cover of Nov. '71 issue? Most hams (all single like me and most married) appreciate the finer things in life and wish to enjoy these pleasures to the fullest! FB on the mag. too.

Russ Kinner WA8ZID
Toledo OH

Many thanks for a good year's reading. Best regards to all at 73 and keep up the good work.

Doug ZL2AWF
Petone NZ

RTTY ART MADE EASY

"Peace Through Victory," originated for RTTY by Don WA6PIR, art by XYL Maxine.

Have you ever wished that you could make some of that RTTY art that you may have printed? Well, so did I at one time. It is a great deal easier than you might think.

We (the XYL Maxine and I) have found that there is much basic art work available from which RTTY pictures may be made. Cartoons, the comic strips, post cards, magazines, newspapers, centerfolds and photographs may all serve as bases for pictures. While these may not be the right size, an inexpensive child's pantagraph may be used to enlarge or reduce them. A portrait of Washington was made from the etching on the dollar bill. While it is not that important, if you have a little sketching talent, that will also help (or enlist your wife and friends as I did).

Having decided on the subject and having the basic art work the right size, run about four feet of paper out of your printer. Use the center portion of the paper for your sketch or carefully tape or glue (white glue works well) the drawing or photo to the paper. Trim the edges so that all is still the same width as originally. Now take out the paper from your printer and insert the four-foot sheet with the sketch on it so that it will be presented to you as it rolls through the machine. Carefully align the edges of the paper on the platen. Use your line feed to bring the top of the sketch into view. With a little practice, you will be able to tell just where any character will strike the paper.

"Hiram, a Bassett Hound Dawg," originated by Don WA6PIR, art by XYL Maxine.

"Fang, A Siamese Pussy Cat," originated by Don WA6PIR, art by XYL Maxine.

You are now ready to overtype the sketch, punching a tape as you go.

We have found that a small selection of characters is all that is really needed to produce either outlined or shaded pictures. While you may not agree with our selection, study the letters and other characters to learn their individual densities. For example, the M and W are the darkest, followed by the H or X and then by the I. Thereafter, you can use the upshifted characters such as the : or ; followed by the " or - or . and the like, depending upon where you want the print to fall. In this way, you may add the shading that you desire or leave certain areas blank like this:

MMHMHHIHII:I::.:... ...:.::I:IHIHHMHMM

going from dark to light and back to dark again. Keep up this process over the entire sketch. Remove the four-foot paper with the sketch from your printer and reinsert your paper stock. Now play out the tape that you have made and see what you have. You will probably be pleasantly surprised. From this point on, we generally take a red pen and indicate on the print where additions, corrections and any changes are to be made and rerun the tape (having folded the marked-up print and following it line by line, using the paper holder and line guide on the printer) to make the corrections, making a new tape at the same time. In most instances, we can now come up with a pretty good picture with a series of five or six corrected tapes.

When overtyping the sketch, it helps to have a strong light directed on the sketch in your machine. This is particularly true if the contrast of the sketch is poor, as it may be in color photos. Also, as you will not be able to see the part of the sketch below the ribbon, we usually take a pencil and outline the areas where the shading will change from one density to another. This way you may be able to get a more complete picture the first time through. While we do not do this, some of the guys have found it helps to make Xerox prints of the original sketches

"Miss Santa," believed to be by WA9CCP, obtained from W9PRO and relayed by WA6PIR.

or photos and to use those for the overtyping, as they eliminate some shading and provide a black and white sketch from which to work. Keep the detail of the original art work as large as you can and don't be afraid to experiment with different letters and techniques. Do clean up the tapes – we generally do this during the first run-through after the overtyping is finished to remove the extra characters and corrections made during the typing. To give you some idea of the time required to complete the pictures, we put in about 20 hours for one of the long playmates that run 30 minutes or so. Most of this is in making the corrections while rerunning the tape. Even after they are apparently finished, we hang them across the room to see how they will look from a distance and then make the final tape with the finishing touches.

Many of the machines in use today have non-overline features so we have quit using overlining. Stay within a 73 character line. Start and end the tape with a series of letters, a couple of carriage returns and about ten line feeds, as this will help the other guy if he is making a reperf tape at his end. Also, keep in mind those who have machines that downshift on space as well as those that do not do so. If you are upshifted and then space and wish another upshifted character, put in another figures character. Of course, the same applies when you want a letter following a space after an upshifted character. At the start of each line, we generally use two carriage returns, the line feed and two letters or figures depending upon how the line starts, to help ensure that the old and tired machines have time to get to the start of a new line. Again, make your tapes as short as possible by taking out any unneeded characters, extra letters, upshifts followed by downshifts and things like extra spaces or downshifts at the end of a line. Above all, be sure to put your credit line at the end, with the hope that others will follow your lead and keep it there.

So if RTTY pictures are your bag, how about trying your hand and making a few? We will not only be pleased to receive them but the eyes here are about to give out!!

The TT-63A as a Display Generator

James J. Wenskus, Jr. K2BEH
329 Ballad Ave.
Rochester, NY 14626

Teletype Repeater TT-63A/FGC is an inexpensive and widely available piece of surplus equipment. Although many amateurs have purchased this unit, problems in getting it into operation have resulted in most TT-63As gathering dust on a shelf or filling up useless space in relay racks. (It has a neat appearance and is fine for impressing neighbors or non-RTTY'ers.)

This article describes a novel use for the TT-63A as a Teletype character-synchronized sweep generator. The TT-63A recognizes a Teletype character as part of its basic function. This characteristic is used to generate a scope presentation in which the Teletype character is always perfectly synchronized, and time marks provided, at either keyboard or machine speeds. The basic concept is applicable to any other surplus Teletype equipment having this recognition capability. The "Selcal" could probably be used in a similar manner.

These modifications will cost less than $5, depending on the state of your junkbox, and shouldn't take more than a couple evenings to build.

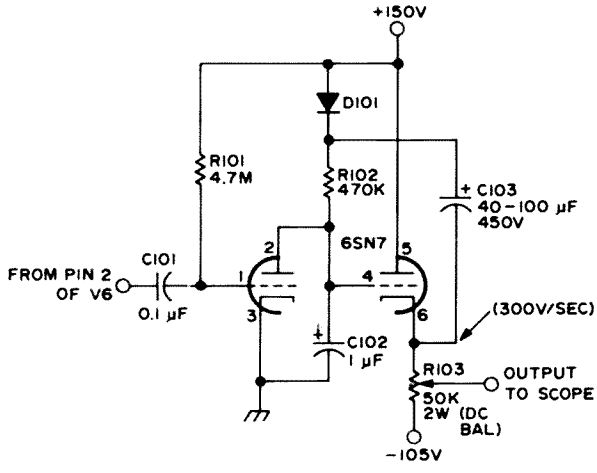

Fig. 1. The bootstrap sweep generator.

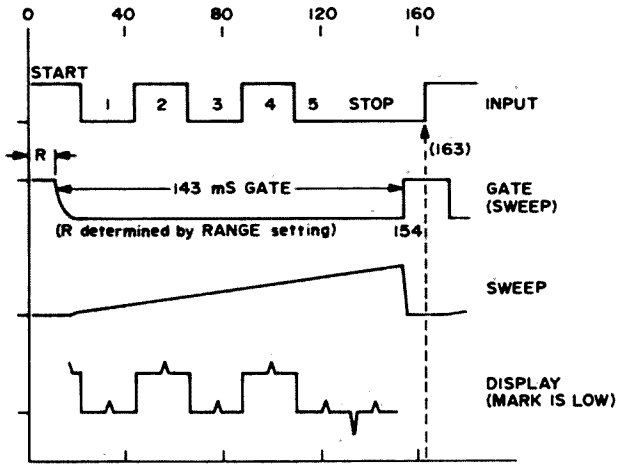

Fig. 2. Y waveforms and time relationships.

A few comments are in order. Attempting to convert this unit to a TU by adding a standard limiter-discriminator front end will not be particularly successful. This is due to two design peculiarities: The TT-63A is extremely susceptible to errors resulting from pulse splitting and the 1 ms sampling pulses coming in this hole. It needs a very good low-pass filter between the discriminator output and the trigger input. By the time you have added a truly effective low-pass filter, you will have probably duplicated half a TT/L without its benefits. Also, the chassis is too crowded for the required extra components. Another unfortunate characteristic is its performance at machine speeds when a "start" pulse is lost; the TT-63A prints several erroneous characters before timing synchronization can be regained. In adddition, if you are not using coax to your receiver, you may possibly pick up hash from the keying relay.

None of these problems will significantly affect its performance as a synchronized character display generator. Adding the simple circuits shown in Figs. 1 and 4 and slightly modifying your TU as shown in Fig. 3 is all that is required to make the TT-63A a truly useful RTTY accessory.

The Bootstrap Circuit Operation

Normally the grid of the 6SN7 is biased positive so that the tube is fully conducting. This effectively removes the charge across C102. When the negative 50V gate from V6 cuts this tube off, C102 begins charging through D101 and R102. The cathode follower portion of the 6SN7 feeds back the output ramp to the high end of R102 to maintain a constant charging rate and provide a linear sawtooth. With the components shown, the output is approximately 45V. The value of C103 is not too critical since the charging of C102 occurs mostly in its linear region even without bootstrapping. Removing C103 affects the amplitude far more than the linearity. It is necessary, however, to use a good quality capacitor for C102 – *don't use an electrolytic!* R103 allows the output signal to be balanced around ground. Some slight loss of signal results from this arrangement but it is effective and allows the scope to be switched from a cross tuning pattern to this pulse analysis mode without making centering adjustments on the scope. It should be noted that the start pulse is drastically shortened on the actual display. This is due to the poor risetime of the leading edge of the gating pulse.

Construction

The bootstrap circuitry is placed where V1, V2 and V3 were originally located. These tubes were part of the original tone portion of the repeater and are not used. The original 6SN7 (V1) is used as the bootstrap tube. One of the 6H6s may be used in place of the semiconductor diode shown in the schematic. The remaining

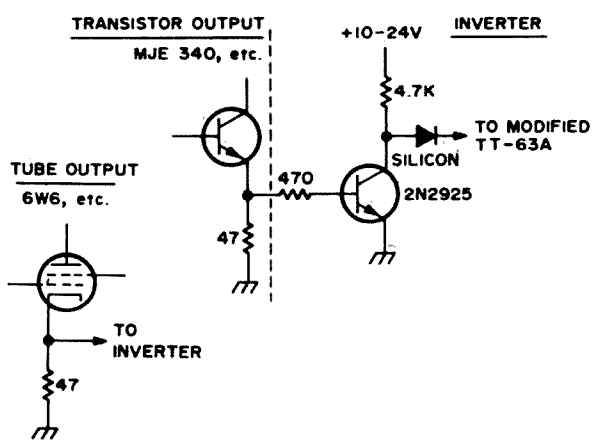

Fig. 3. Modifications of typical TU output stages to provide proper polarity pulses to the TT-63A input.

sockets are handy as tie points for the bootstrap components. Be careful when trimming wires on these sockets as several terminals are used for tie points for other stages. The sweep centering pot is a screwdriver adjustment type and can be located on the left side of the chassis after removing some unused tone parts.

The pickoff for the time-marked pulse display is shifted from its original point to the junction of resistors R55, R56 and R57. This change increases the amplitude of the time markers over the original point. A slight negative dc bias is introduced on the display by making this change but the resulting improvement in marker visibility is worth this slight inconvenience. The resulting display has vigorous negative pips where the pulse transitions should occur and lower amplitude positive sampling pulses. The range control centers the received pulses between these negative markers.

Connecting the TU

For proper operation of the repeater, the input to the Schmitt trigger must go negative on the stop mark. A few additional parts can take care of this requirement. Since most TUs can be readily modified to provide positive mark outputs; a simple inverter, shown in Fig. 3., is added to provide positive space pulses. The new repeater input circuit in Fig. 4 shifts the resulting 0V mark output from the inverter to a negative mark. My measurements show the Schmitt trigger turns on at −2.75V and off at −2V. To get the unit in operation, rotate R6 to the position which gives the best blinking of the neon. This setting is not critical.

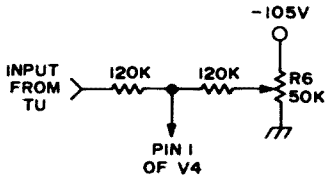

Fig. 4. TT-63A input modification to provide negative mark voltage for proper operation of V4. R6 is the input attenuator already in the unit.

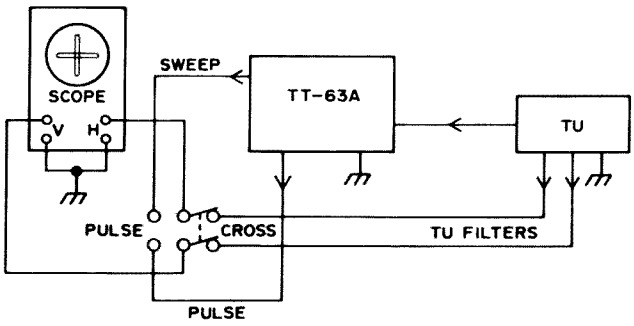

Fig. 5. Block diagram of typical component interconnections. The TT-63A subpanel can be rewired to do the required switching. Attenuators can be added to balance the voltages across the filters to that of the sweep and pulse voltages so that the scope gain does not need to be adjusted when switching displays.

Usage

When this system is set up, you can readily observe distortions on incoming signals, dirty contacts, the poor efficiency of your low-pass filters, etc. If your keyboard is in series with your selector magnets, you can readily check your own contacts. When I first tried this on my transistor TU, which had only 24V available to drive the selector magnet, the observed pulse distortion was appalling. Going to a high-voltage loop made the pulses look as they should. The vertical input to the scope can be connected to various areas of your TU and the pulses chased through always in perfect sync. This is a truly enlightening experience.

I use a 5 in. scope for my monitoring. Anything less will make observing the pulses too difficult. A dc scope must be used in order to pass these relatively slow waveforms without distortion. I find that the pulses are best viewed if the scope gain is not set too high. They are easiest to watch when they are almost square on the screen.

A very nice feature of this system is that you can tell if you have a legitimate RTTY signal tuned in and whether it is right side up, the right speed, etc., without turning on your printer. You merely see if a synchronized sweep is being generated by the TT-63A. This is possible only with a legitimate signal. This certainly saves a lot of useless clatter, bells ringing, waste paper, etc. when tuning across the bands.

TELEVISION MONITOR

After building a Flying Spot TV camera, I acquired an old TV for a monitor. It was a typical early 1950 vintage set with a 10 in. screen and a 50 in. cabinet which a local TV repairman was happy to part with for $5. (Good thing I didn't have to pay for it by the pound!) It took only half an hour to modify the set for use with the camera. I was lucky, as it required no phase inverter or extra video amplification. But it was by no means the perfect monitor – modification required the addition of a SPDT switch, coaxial connector, a 75Ω resistor, and a short section of coaxial cable.

After using the converted monitor for several months, I began to modify the set even further. The controls were in the wrong spot . . . why leave the tuner connected, it just uses more power . . . get rid of that i-f strip. Finally, the only thing that remained was the power supply, the sync and sweep section and the video amplifier section. Even the original CRT went to the junkman. In its place I used an 8XP4 universal substitute tube. At this point no one could recognize the original TV configuration. I had even considered rack mounting the residue, but gave that idea up in favor of building a new

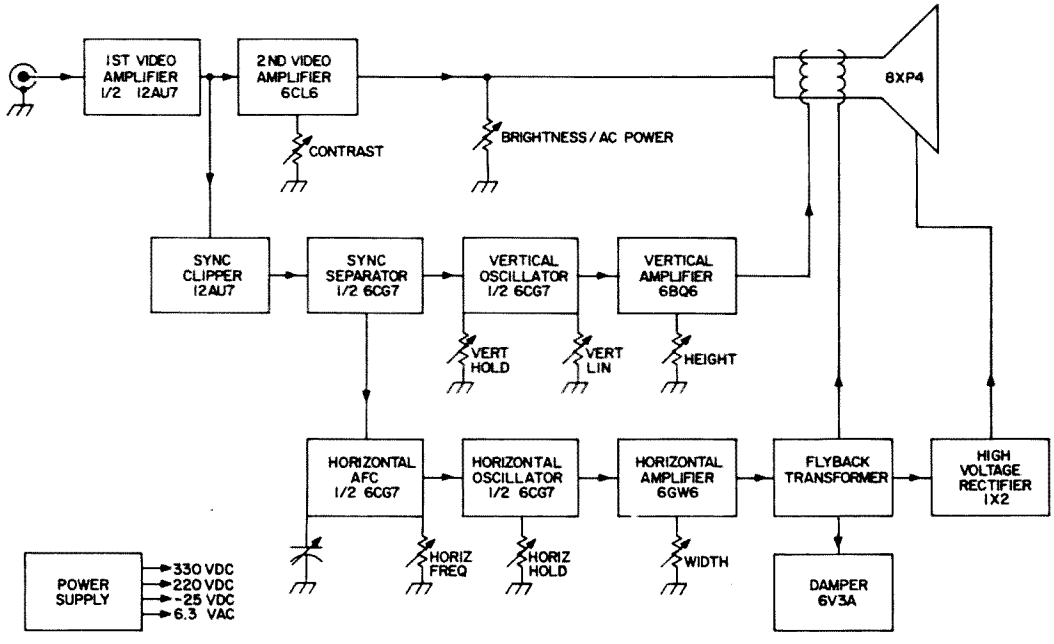

Fig. 1. Block diagram of the TV monitor.

AND SOME OF OUR

CONVERTERS

If you need a low noise pre-amp in a hurry for communications or instrumentation, we can fill your order custom tuned to any frequency from 5 MHz. to 475 MHz. within 24 hours by air mail or special delivery. All you pay is our regular low price plus C.O.D. shipping charges. This rush service is also available on some of our stock converters. See Oct., Nov. and Dec. 1971 issues of 73 Magazine for our 2 page condensed catalog. Call us between 9AM and 4PM, Monday thru Friday except holidays (no collect calls please). If line is busy keep trying.

PHONE: 212-468-2720

VANGUARD LABS 196-23 JAMAICA AVE. HOLLIS, N.Y. 11423

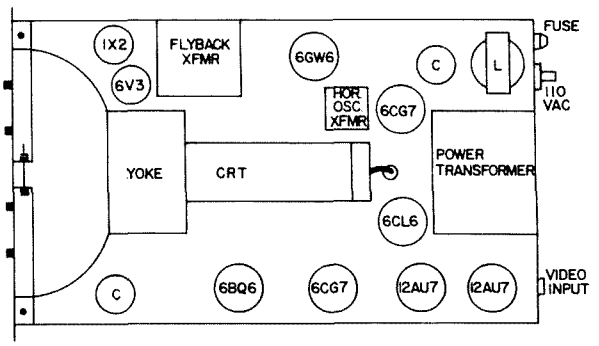

Fig. 2. The physical layout of the monitor.

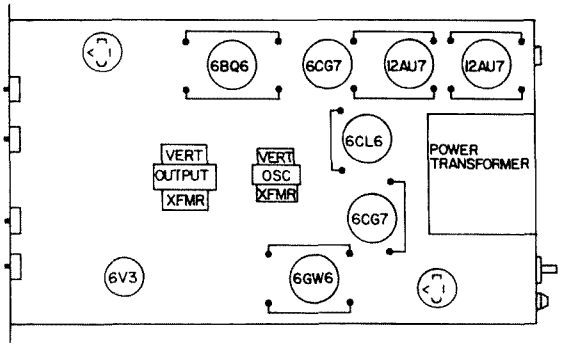
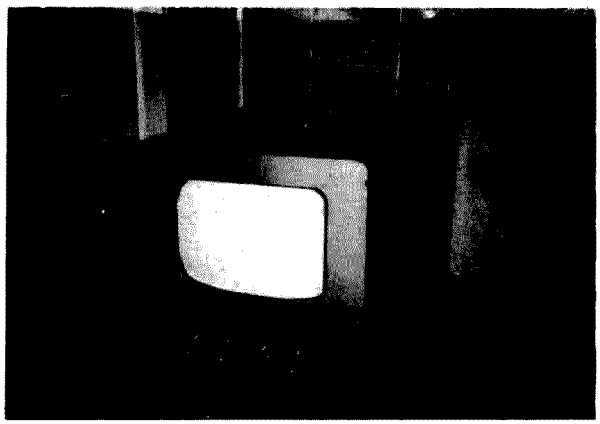
monitor. Several points came to mind while designing the monitor. First of all I would limit construction cost to a maximum of $50. It must not employ any parts unavailable to the average ham. The operational controls must be located on the front panel for convenience. The monitor must be simple to adjust, using a minimum of test equipment. Finally, it must lend itself to modification to suit the individual builder.

Using these criteria, I was able to construct a monitor for $22 (less CRT). I was lucky enough to have a CRT left over from a previous project. A new 8XP4 will cost $22 to $28. The principal item I had to purchase was the cabinet. I used a Premier CC-2000 with a 3x10x27 in. aluminum chassis. The majority of parts came from several salvaged TVs obtained for the asking from a TV shop. Although I would have had no difficulty obtaining a horizontal output (flyback) transformer from a junked set, I chose to purchase a new one for $1. If you choose to use a CRT such as a 5AXP4 or 5FP4 (requires focus magnet) you may want to use a 70° yoke and transformer, also costing $1. 110° deflection components are also





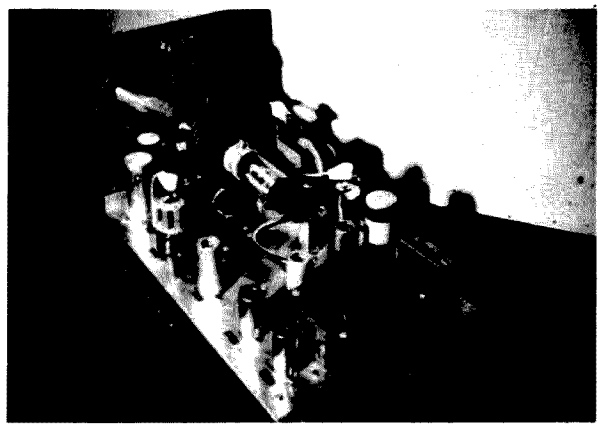


Fig. 3. To facilitate wiring, terminal strips are mounted in parallel rows.

Monitor exterior. . .

. . .and interior

available commercially. All other parts came from my junkbox.

The operation of the monitor can best be described by referring to the block diagram (Fig. 1). The input may be from ½ to 10V negative video from any 75Ω source. The output of the first video amplifier is fed to the second video amplifier and to the sync clipper. The output of the second video amplifier is applied to the control grid of the CRT.

The sync clipper consists of a normal voltage amplifier followed by a saturated amplifier. The output of the saturated amplifier contains only sync information (i.e. pulses of 60 Hz and 15.75 kHz). From the saturated amplifier the sync pulses are coupled to the sync separator. The output of the sync separator is sent to an integrator (low-pass) circuit (vertical sync) and a differentiator (high-pass) circuit (horizontal sync).

The differentiator output is coupled to the horizontal afc (control) tube. The horizontal afc keeps the horizontal oscillator (blocking oscillator) locked on frequency. The output of the horizontal oscillator is modified by the 330 pF capacitor to a sawtooth waveform at the grid of the horizontal amplifier tube. The output of the horizontal amplifier is coupled to the horizontal section of the deflection yoke by the horizontal output transformer.

High voltage pulses developed by the flyback transformer are rectified by the HV rectifier to provide 12.5 kV for the CRT. The damper suppresses oscillations in the horizontal deflection coil and provides an increased voltage (B+ boost) for the horizontal amplifier and the vertical oscillator.

The power supply provides 330V dc at 100 mA, 220V dc at 100 mA, −25V dc for fixed bias and 6.3V ac for all filaments.

The power supply was the most difficult part of the construction project. Three different circuits were tried before an acceptable supply was achieved. The supply uses silicon rectifiers throughout. Normally

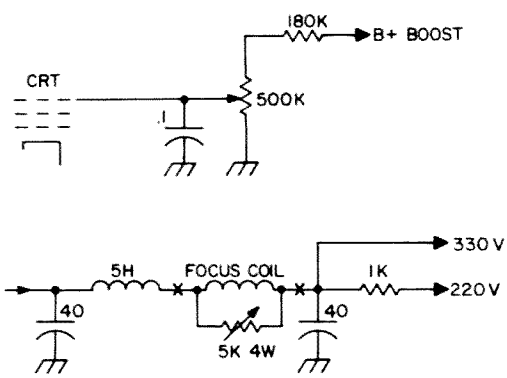

Fig. 4a and b. Two methods of supplying focus voltage/current to the CRT.

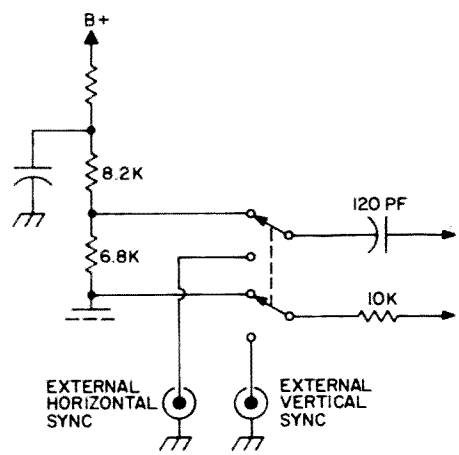

Fig. 5. A suggested modification for sync only input.

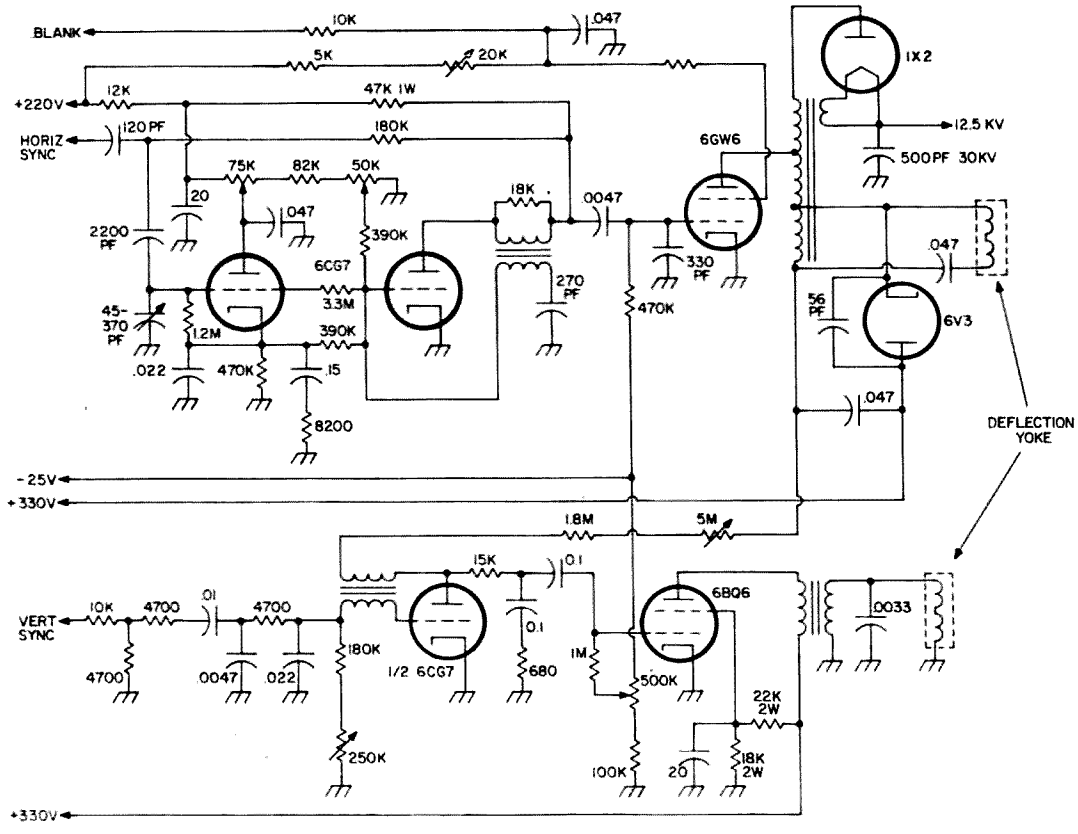

Fig. 6. Schematic of the deflection and high voltage section.

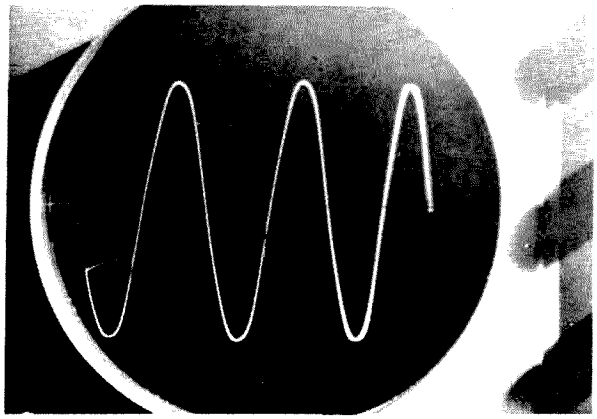
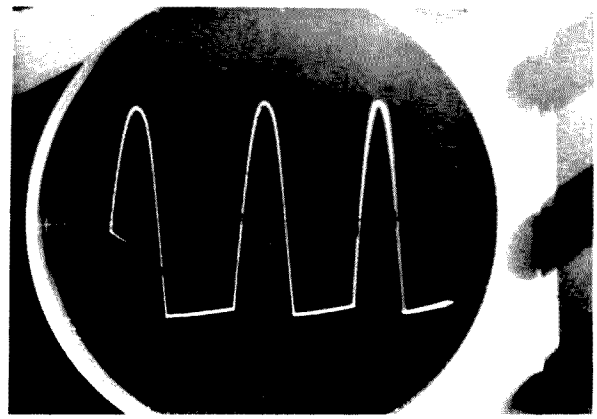


the power transformers from TV sets have three filament windings, two 6V and one 5V. They were used to obtain the negative bias voltage using a simple half-wave rectifier. If your transformer has only two 6V or one 6V and 5V windings, a voltage doubler should be used to provide the necessary −25V bias. The electrolytic capacitors used in the power supply section may have a greater capacity than those shown, depending upon what you have available; however, do not use less.

Mounting of the CRT may present some problems. I modified a mounting from a 17 in. set for my use. To simplify mechanical work, I obtained a yoke which clamped to the neck of the CRT. It required no other mechanical support, and there were centering magnets included on the assembly.



The layout shown in Fig. 2 was used. I encountered no problems with stray magnetic fields. The vertical output transformer and the vertical blocking oscillator transformers were located under the chassis. I used two four-section electrolytic capacitors, along with a couple of lead type electrolytics. There is sufficient room for another multisection twistlock electrolytic if you desire. To simplify wiring, 10 seven-terminal (2 ground) terminal strips were mounted in parallel rows as shown in Fig. 3. Other smaller terminal strips may be added as desired.

After wiring is completed, check carefully for errors before operating the monitor. For the smoke test, I recommend removing the horizontal output tube (6GW6) and the vertical output tube (6BQ6) and temporarily connecting the hot end of the height control to the 330V buss instead of the B+ boost. In my original model, I had the height control going to the 330V buss, but I was unable to adjust the height and vertical linearity satisfactorily. During normal operation the B+ boost voltage is 700V. This gives a very linear vertical sweep.

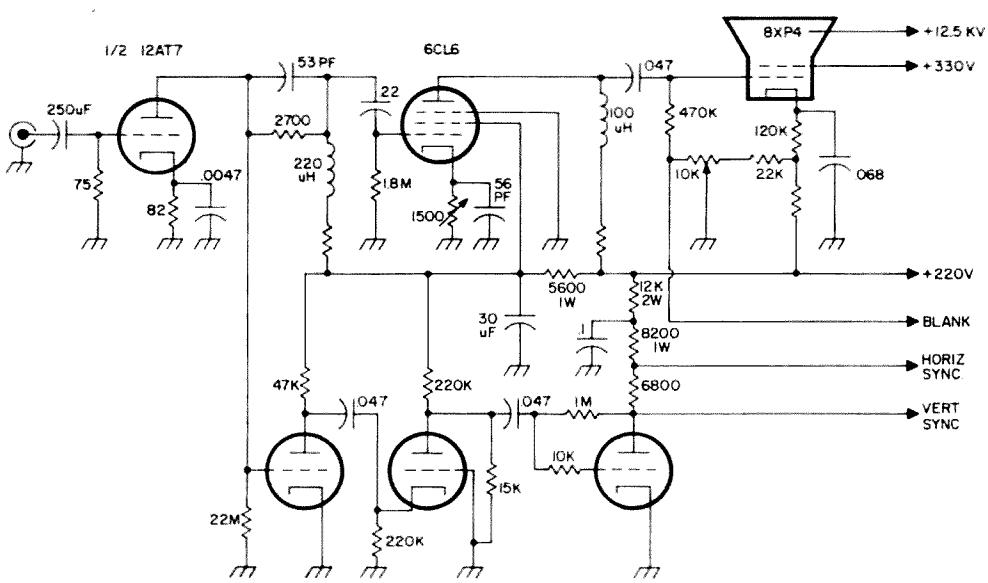
The test equipment needed for checkout are a VTVM with high voltage probe, an oscilloscope with a low capacity probe, and a source of ½ to 10V negative composite video. While a scope is not absolutely necessary, it is very helpful.

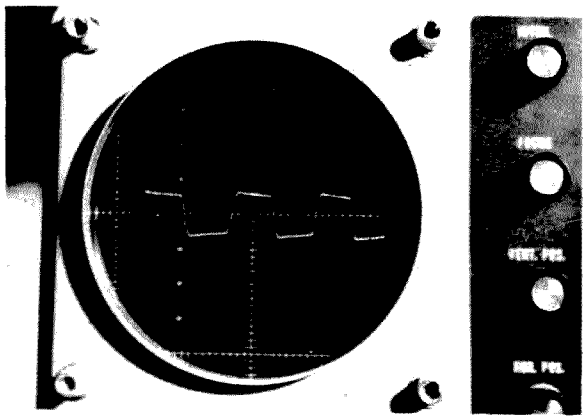
Vertical oscillator grid voltage waveform.

Vertical output plate voltage waveform.

Alignment Procedure

1. Turn on the monitor and allow it to warm up for 5 minutes. Keep a sharp eye out for overheating of resistors or tubes.
2. Set all controls at mid-rotation.
3. Connect the source of video to the monitor.
4. Check each video stage for signal. You should be able to trace it right up to the CRT control grid.
5. Check vertical oscillator for correct operation.
6. Insure that −25V is available for the vertical and horizontal amplifier grids before proceeding. Then insert the vertical output tube. Be sure that the deflection yoke is connected. If it isn't connected the tube and the transformer may be damaged. Using low capacity probe, check the waveform across the vertical deflection yoke. Rotate the vertical hold, vertical linearity, and height controls and observe their effects on the waveform. Using the VTVM, set the vertical amplifier control grid voltage to 15V using the vertical linearity control.
7. Check the horizontal oscillator using the low capacity probe for proper operation. By adjusting the horizontal frequency, horizontal hold and horizontal stability there should be a 15.75 kHz, 60–90V peak-to-peak sawtooth waveform. When you are satisfied that the oscillator is functioning correctly, turn off the monitor, insert the





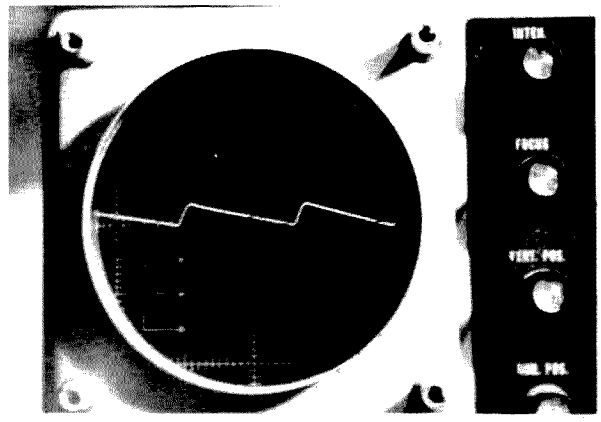


Fig. 7. The video amplifiers and sync separator/clipper.

1000 Hz video test square wave at CRT grid.

Horizontal deflection coil current waveform.

6GW6 and reconnect the height control to the B+ boost.

8. Re-energize the monitor, again looking for overheating of resistors and tubes. Adjust the brightness control to about mid-rotation. The CRT should light and a raster should appear. With the VTVM (using the HV probe) check for B+ boost (500 to 700V) and HV (10 to 15 kV). Adjust the width control for 100V on screen of 6GW6. Adjust the height control for a 100V peak-to-peak 60 Hz sawtooth on the vertical amplifier control grid.
9. By adjusting the front panel controls, you should be able to obtain a picture. Adjustment of the yoke (mine had centering magnets attached) may be necessary. If the picture is upside down or mirror image, reverse the necessary yoke leads.
10. Fine adjustment may be accomplished by using standard TV alignment procedures. Notice that the horizontal hold and horizontal frequency controls interact, as do the width and brightness.

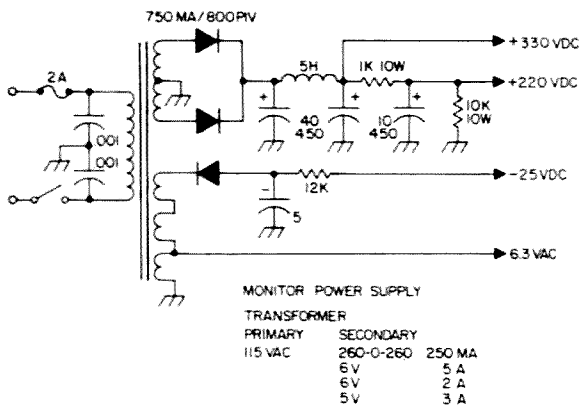

Fig. 8. Monitor power supply.

I get carried away using silicon diodes. Originally I used a 3000 PIV 200 mA diode for the damper. After two frustrating failures, I used a 6V3A. If any of you more persistent types desire to try a silicon diode, use at least a 5 kV PIV 200 mA diode. If you use a 6V3A remember that it has a cathode cap and not a plate cap. It won't work the other way!

As for substitution of tubes, a 6BQ6 could be used in place of the 6GW6. However, with the high B+ boost voltage present (700V) I used a 6GW6.

I used an 8XP4 universal test tube, although any one of several CRTs may be used. An 8YP4 may be used if 110° deflection components are used. An 8KP4 may be used if correct focus voltage is supplied to the focus anode. An 8DP4 may be used also; however, it requires – in addition to a focus voltage – a single field ion trap. A 5 in. tube such as a 5AXP4, 5AHP4 or a surplus 5FP4 could also be used. The 5AXF4 requires no external focus supply. The 5AHP4 requires a focus supply of 0 to 250V. The 5FP4 is an electromagnetic focus tube. Figures 4a and 4b show methods of supplying focus voltage/current for other CRTs.

This monitor was designed as a basic building block for future projects. For those with a master sync generator, a *sync only* input may be desirable. A suggested modification is shown in Fig. 5. Other changes/adaptations may be made to the basic design to fill the requirements of the builder.

73 Tests

THE ICOM IC-21 TRANSCEIVER

The word has leaked out around the U.S. about the Japanese IC-20 and IC-21 transceivers, fueled by a handful of units brought back by visitors to Japan and returning servicemen. Now, at last, these goodies are being made available through a U.S. importer.

Adirondack Radio was kind enough to lend their first sample for a test and it certainly was impressive. The most spectacular aspect of the rig is the 24-channel frequency switch, complete with an easy-to-get-at board for the 24 crystals and tweaking capacitors immediately at hand.

Now, while you may live in an area which only has one or two repeaters, those of us in the northeast are living in an entirely different world, one jammed with repeaters on just about every pair of channels. Though the 73 HQ is in a remote corner of lower New Hampshire, there are now about 17 repeaters that can be used with a simple antenna. Three miles away, from the top of Pack Monadnock mountain, where we test out new equipment, there are a whole bunch more within easy reach. A 24-channel transceiver looks awfully good for a spot like this.

The IC-21 has so many nice features that it is difficult to decide which is the most desirable. It has an ac supply built in and will operate from either 115V ac or 13.6V dc, making it a dandy unit for both base and mobile applications . . . and particularly valuable to the operator who wants to be able to use one rig both in the car and at home.

The transmitter puts out 10 watts on the high power position of the output switch and one watt on the low position, making it possible to save on battery power when operating through most repeaters.

Experienced FM operators will appreciate the variety of meters on the IC-21. Just above the channel switch is a deviation meter which indicates how much off frequency the incoming signal is. This meter is calibrated plus and minus 5 kHz. There is a control on the front panel to compensate for this off-channel stuff . . . a Receiver Incremental Tuning control which swings the receiver back and forth about 5 kHz. Since not all 94 repeaters are on 94 and not all 76 repeaters are exactly on 76, this is a handy control to have when you are moving from one area to another.

The S-meter on the receiver comes in handy when you want to identify which of several repeaters you are hearing and there is no identification at the moment. At our mountain lab site we hear W1ALE in Concord on 94 at umpteen over 9, WA1MHN in Somerville, Mass., at S-9, WA1KGR in Holyoke, Mass., at S-8, and W1KOO on Mt. Mansfield, Vt., at S-1, so you can tell from the S-meter reading exactly which repeater is being heard at any time. On 88 the S-meter permits instant identification between W1ABI, WA1KFX, K1AOI, W1ZAW, WA1JTB, and WA1KHK.

The S-meter becomes a plate tuning meter on transmit or an SWR-meter, with a flick of the front panel switch. There is a

ADIRONDACK Proudly Presents . . .

the IC-21 **$389.00 Net**

- 24 Channel capability.
- A new high – very useful in these days of new repeaters going on the air constantly.
- Front panel – P.A. tune control – a real advantage to get maximum output.
- Separate S and discriminator meter ±5 KHz – panel.
- R.I.T. – control on receive – either 1 watt or 10 watt output.
- S and SWR meter combined.
- Remote VFO plug.
- 12 volt DC or 110 volt AC operation.
- AC and DC cable supply.
- Discriminator meter – a real addition.
- Crystals – supplied with 4 channels.

This is an entirely new approach in 2 meter FM gear. Just imagine 24 channel capability, SWR meter and S meter, plus netting condenser on each transmit and transceive crystal, plus many other features original with this unit.

Manufactured by Inoue Communication Equipment Corp. of Osaka, Japan, already well known to 2 meter FM users.

FM YOUR GONSET COMMUNICATOR

- Newl Plug-in modulator puts the Communicator transmitter on FM.
- No modification or rewiring of your Communicator. Just plug into mike jack and crystal socket.
- Compact self-contained modulator measures 4" x 3" x 1½".
- Works with Communicator I, II, III, and IV.
- FM at a tenth the cost of a new rig.
- Frequency adjust for netting built in.
- Built-in tone burst available. Keyed by push-to-talk switch.
- $34.50 postpaid U.S.A. Built-in tone burst $10.00. Specify Communicator model and tone-burst frequency. 5% tax in California. (HC-17/U crystal and 9 volt transistor battery not supplied.)
- Send for free descriptive brochure.

PALOMAR ENGINEERS
BOX 455, ESCONDIDO, CA 92025

plate tuning control on the panel, permitting the plate to be peaked on any channel, thus overcoming the serious drop in power you suffer with some rigs when you change frequency from one end of the band to the other.

The mike gain control on the front panel is useful for setting your deviation to match the repeater you are using. Some are wideband, some narrow, and some compromises. With a little fiddling around you can find out what works best with each repeater and use that deviation from then on.

Some of the statistics, briefly: weight 14 lbs; size 4½" high, 9" x 10", will obviously fit under most dashboards; draws 0.2 A on receive, 2.1 A on high power, and 1.2 A on low power; uses 18 MHz crystals for the transmitter and 15 MHz for the receiver; i-f is the usual 10.7 and 455 kHz.

An automatic protection circuit disables the driver transistor if anything happens to the antenna, thus keeping the final transistor from going west when the antenna is shorted or opens up.

A low-pass filter on the output is designed to keep interference down to neighboring television sets.

The IC-21 is designed to be mounted by means of a bracket in the car and a built-in folding foot stand angles it for use on the operating table.

An external vfo may be used with the IC-21. It plugs into one side of the cabinet. There is a jack in the back for an external speaker, which is very handy for car installations where you would prefer to listen to the regular car radio speaker than the smaller one on the transceiver.

Since the transmitter and receiver units are independent of each other, a good technician might be able to convert this rig rather easily into a repeater. It wouldn't take a whole lot of work. The modular construction of this rig would make such a "conversion" much easier than with most transceivers. The fact is that you can get at almost everything on the IC-21.

The IC-21 is being imported by Adirondack Radio, Amsterdam, New York and sells for $389.00.

73 Tests The REGENCY Transcan FM Transceiver

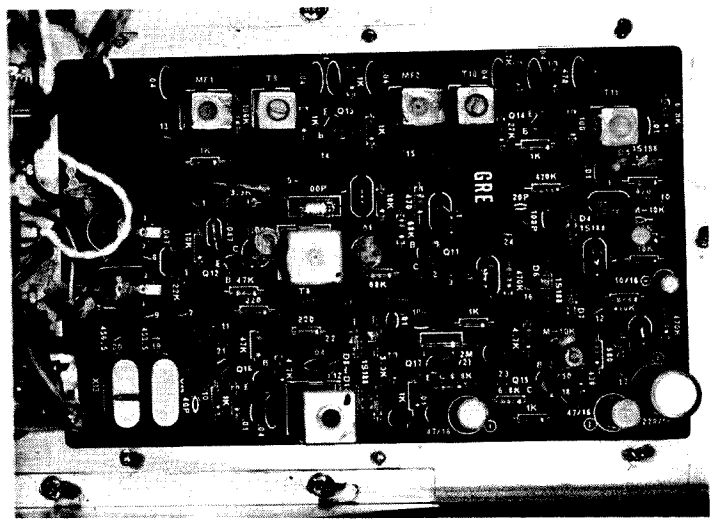
A scanning transceiver was the obvious next step in two meter FM transceivers. There are so many repeaters in action today, even in the more remote parts of the country, that the FMer needs some way of keeping track of which are being used. Back in the old days, a year ago, when there was only one repeater in most areas, a simple monitor receiver was all that was needed to keep in contact.

As 1972 unfolds we find that most major urban areas have four to six repeater channels perking and, unless the FMer has his hand on the channel switch a whole lot, he misses out on most of what is happening. It gets to be quite a drag to reach up and switch through all the channels every few minutes. It is a lot better to have a couple of ICs and some transistors doing that for you, automatically.

Regency has married their scanning VHF receiver and their very popular HR-2 two meter FM transceiver and come up with a package which does everything for you except keep the log. The receiver scans eight crystal controlled channels and, when any one becomes active the light turns on, the scanning stops and the squelch turns off so you can hear the station. Each of the eight receive channels may be locked out of the scanning function by pushing a button over the channel lamp. This is handy when one channel is active and you want to scan all but that one . . . or two, etc.

There are six crystal transmit channels which are selected by the buttons under the receive channel lamps, which leaves two receive channels which can share any of the six transmit channels with another receive channel. Pushing the transmit button locks the receiver to that channel until you push the "scan" button which disconnects all transmit crystals and sets the receiver to scanning again.

This setup is ideal in the areas I frequent, fitting the six repeaters we use in New Hampshire and southern Vermont. When I head down Boston way I change the crystals for the six active repeaters down there (W1QFD, WA1KGS, WA1MHN, WA1NJR, W1HWK, and WA1KGO). If I'm driving to New York, which happens often, I load up for WA1KGQ, WA1KGR, WA1KGD, WA1KGK, WA1KHK, and WA2SUR. And so it goes, with my being able to talk through a selection of repeaters no matter where I am.



The Transcan is extremely handy at 73 HQ where I monitor not only the six fairly local repeaters, but also listen for calls on 76 and 94 simplex from passing FMers. We have a pot of coffee at the ready for visiting amateurs and do appreciate the company. The Transcan has also alerted me to several band openings which have permitted me to talk down into New York and even points further away.

The scanning function is accomplished by a couple of ICs which switch the receive channels by means of diodes and sample the channels, stopping when the squelch is operated by a carrier. There is automatic protection of that expensive output transistor too, with a little circuit that senses if the antenna opens or is shorted and turns off the drive to the final.

All in all, Regency has come up with one of the best fun-makers for two meter FM yet. I don't have time to switch through all the channels while I'm driving to see who might be coming through. The Transcan does it for me and even the shortest blip of a carrier stops everything and lights up the active channel. The price is $319 for the mobile model and $349 for the desk model with built-in 117V ac power supply.

. . .W2NSD/1

73 Reviews The Allied AX-190 Ham Receiver

If all receivers performed as well as they looked, a ham would have no trouble in obtaining a good one. The trick is finding the good receiver that is behind the pretty panel. The Allied AX-190 is such a one. Behind the brushed aluminum front are five printed circuit boards that hold all components in very neat arrangements. On one of them is the four FET front end which is rated at 0.5 μV sensitivity at 10 dB S/N. Our test unit performed very well with no more than a longwire, and we have no reason to doubt the accuracy of the manufacturer's statement. This receiver picked up many weak stations that other radios could not hear. The preselector is very sharp and sensitive and really peaks up signals while rejecting interference from strong off-frequency stations. The receiver covers eighty through all of ten meters in 500 kHz bands. There is also provision for adding another segment of the 3.5 – 10 MHz range.

For those strong signals that cause QRM, the Q-Multiplier does an excellent job of eliminating heterodynes and peaking the desired signal. This feature is certainly a desirable one for CW and SSB ops. Signals here were raised by thirty to forty decibels, and when the rejection mode was selected, annoying whistles were eliminated.

CW and SSB are received well by means of a four diode balanced modulator circuit. The first oscillator and bfo are crystal controlled for sharp and accurate tuning. The audio is clean and pure, and almost hi-fi – in short, very comfortable. Dual conversion and ceramic filter add measurably to easy listening.

For those who might want to listen to AM stations that are outside the ham bands, an AM position and AM with ANL are provided on the function switch. Incidentally, the diode noise limiter performs very well to take out ignition and electrical noises (i.e., the fluorescent light on my desk).

As for minor features that add to the pleasure of owning the AX-190, there is a 25 and 100 kHz calibrator for accuracy of the smooth tuning vfo knob which has one kilohertz markings on the resettable skirt. The rig also has provision for operation directly off of 12V dc, making the rig valuable for mobile, Field Day, emergency, and portable use. Antenna input is a common SO-239 chassis connector, provision for muting, and vfo output round out the features of this receiver. One other valuable feature of the rig is the accompanying instruction manual. It is complete with an excellent theory of operation section that includes excerpts of the complete schematic showing the various stages in their individual and combined design states.

For the ham who is looking for a good receiver, portable, or emergency receiver, at $249.95 this receiver needs careful consideration. Novices in particular should keep in mind that a few extra dollars on the receiver purchase can add proportionally greater enjoyment to his operating experiences. And when upgrading his license, this receiver will keep its value in the station.

PHONE PHREAKS VS Ma BELL

"Little Box Blue, get on the horn" is the call of a new band of public nuisances, the self-styled "Phone Phreaks" who have been using a small electronic device, known as a "Blue Box," to defraud the telephone services of an estimated half million dollars a year.

73 talked with Dennis Mollura at the Bell headquarters in New York about these Blue Box activities.

First, Mr. Mollura described Blue Box operation:

"They are used to call the network signalling function on the telephone network. If you build a Blue Box that has the proper tones and you know how to use it you could tap out the right tones to give the network its command; then you'd be able to avoid our automatic billing equipment."

These tones are the twelve dual-tone combinations of six frequencies used only for network calling frequencies, and are not the same as a standard Touchtone® phone would produce. You may have noticed, after dialing a long distance call, a rapid succession of higher-than-Touchtone® frequency tone-pairs lasting about a second. These are the network control tones.

A Blue Box user first seizes a long distance line by phoning a toll-free long distance number, most often a directory assistance or IN-WATS (area code 800) number, then hanging up on the callee while retaining the circuit by generating his own 2600 Hertz "disconnect" tone. The 2600 Hertz tone would normally not appear on line until the caller has hung up, and once sensed, is regarded by switching equipment as a signal to disconnect. The captured line is then used to call anywhere in the world at the caller's whim. Most "Phone Phreaks" figure they're getting away with it, but the feeling is usually ephemeral.

"There are three ways which we use to try to detect Blue Box fraud; number one would be plant service center testing (with very common electrical testing equipment) . . . another way is traffic pattern analyses . . . then the third way is computer programming. The computers are watching the networks and they . . . can spot trouble . . . and kick out a trouble report card."

It would appear that most of the current users of Blue Boxes are now at this point in telephone company investigations. They have some unpleasant surprises in store for them if they should be so naive as to think that this is as far as the investigations go.

"When we suspect a case we can put on sophisticated electronic gear . . . which can help us track down the people.

"We've . . . begun a nationwide crackdown. In 1970 there were six people arrested, two convicted, four cases pending. So far this year (September), thirty-three arrests, eighteen convictions, fourteen pending, one dismissed. In the Montana area, a group of ten people . . . were using Blue Boxes. We (actually, the FBI) moved in on them . . . they were indicted . . . and arraigned, and the evidence was so overwhelming that seven of the ten pleaded guilty right off the bat, two of the cases are pending, and one is dismissed."

Naturally, the Blue Box users aren't hurting anybody, unless you feel that having to pay their way yourself is an imposition.

"People are trespassing on the telephone network. They're literally stealing service, and actually increasing the cost of telephone service for people who do pay. I can describe this as like a guy getting on a turnpike and not stopping at a toll booth. He's creating a demand for service, but he's not contributing his share. "Our losses due to Blue Box fraud . . . we're estimating at about five hundred thousand a year."

With a half million dollars a year at stake, why not just clamp right down?

"One of the reasons that we gather evidence for so long, like in the Montana case, is to establish what the person's calling pattern is, to try to determine when he got the box, how often he used it, and where he called. Once we establish a pattern and can pinpoint when he got the box, then we go for full restitution. In cases we've been able to get it."

So far, no amateur radio operators have been involved, but the people who were involved might well have become hams.

"Of the thirty-three people arrested this year, twenty of them were students, one was a private detective, one was a communications man, and most of the rest had electronics background interest."

What is the phone company position on the use of these devices?

"We consider this a very serious matter. People are trespassing on the telephone network. We do have means of detection, and we are confident that we are eventually going to catch them all. When we get them, we are going to press to the fullest extent of the law, and we're going after full restitution of the money we've lost so far."

Amateurs who have been using 2600 Hertz notch filters and 3400 Hertz roll-off low pass filters in conjunction with phone patching have most of the protection necessary to prevent accidental interference with telephone service.

'The Blue Box enables you to place calls without charge. There's another electronic device which would enable people calling you not to be charged. I'm sure you're very familiar with this. I have an article written by you in the September 73. There was some concern. Someone in the telephone company spotted the article and was somewhat concerned about it. I checked it through and it's a legitimate article. It has a disclaimer at the end . . .there's no problem."

Chester County (PA) Detective Ronald Johnson (right) displays an illegal "blue box" used to bypass toll charges and seize long distance telephone circuits. Johnson and Chief of County Detectives Eugene Sharpe (left) were part of a law enforcement team (September 27, 1970) which raided several Chester County residences of suspected "phone phreaks." The "phreaks" use homemade electronic generating devices such as the "blue box" to place free long distance calls all over the world, sometimes for hours at a stretch. Four persons were arrested in connection with charges ranging from toll fraud to impersonation of telephone company employees and, in one case, wiretapping. Authorities said "several carloads" of illegal equipment were confiscated, some of which is shown here.

Most of the details concerning the particulars of design of the equipment used by the phone company in tracking down the Blue Box Banditos must, of course, remain confidential for the moment. 73 will continue to monitor developments in the case of the Phone Phreaks versus Ma Bell, and will release pertinent new developments as they become available.

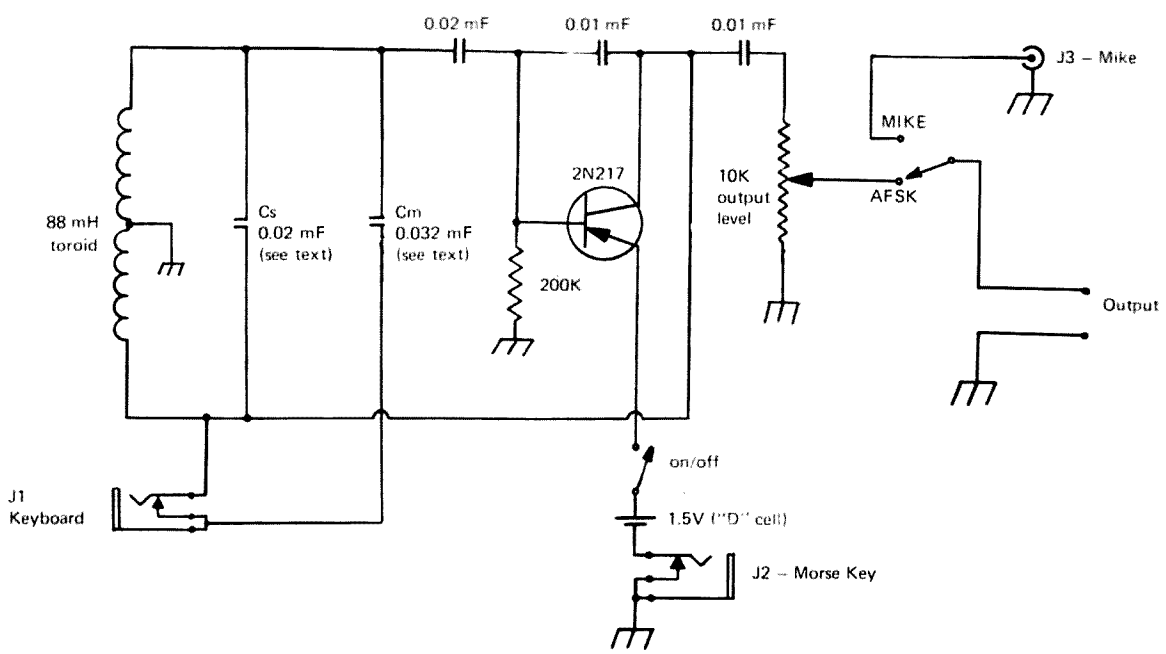
AFSK REVISITED

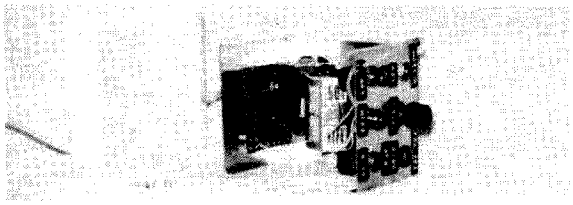
Marc I. Leavey WA3AJR
9412 Adelphi Road, Apt. 202
Adelphi MD 20783

Many hams are lured into the wonderful world of Teletype by the promise of unattended autostart, automatic message handling, or the ability to send fancy holiday greetings. They often find, however, that such operation is practical only on VHF, where non-drifting, non-fading signals make such transmissions easy. Such a finding is not wholly true. Although sophisticated converters can work wonders on the lower frequencies, advanced circuitry is hardly the answer a newcomer to Teletype needs. Unfortunately, that is about all he has gotten – until now. Unlike earlier circuits, the audio frequency shift keying (AFSK) generator described here uses a bare minimum of parts. It gives a reasonably good sine wave output and – using the keying technique included – a minimum of transits or bias. The keying technique referred to is the application of a new device, the magnetic reed relay, to a Teletype keyer. The reed relay can be used not only to key this AFSK generator, but standard FSK units as well.

Simple circuits published previously have contained at least two transistors and a reasonable amount of other software. A look at the schematic, Fig. 1, shows this oscillator to have only one transistor and a minimum of other components. The actual audio shift is accomplished by switching an additional capacitance in parallel with the toroid to lower the tone on "mark." On "space," the switch is open and a higher tone (from less parallel capacitance) is generated. Although Cs and Cm are shown as one capacitor each, they are in reality several capacitors paralleled to give the desired resonant frequency. For such work, you cannot rely solely on the marked value of the capacitor. Tolerance variations can play havoc with combinations set up in that manner. Rather, true trial and error should be used to determine the values after the rest of the circuit is completed.

For newcomers, the use of Lissajous Figures is the most practical method of





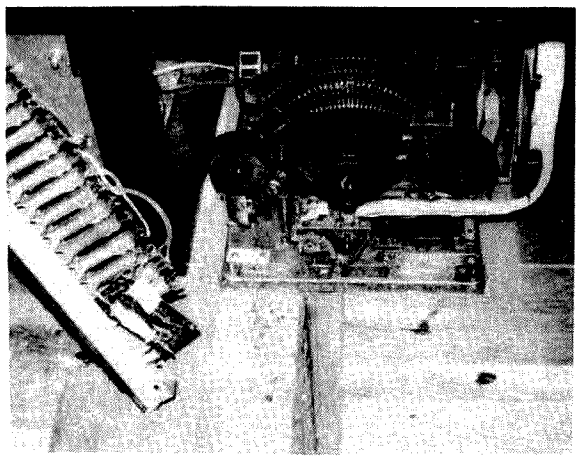


Fig. 1. Schematic of AFSK tone generator.

This is an overall view of the AFSK unit, showing front panel and interior circuitry.

audio frequency determination. Briefly, setting up the circuit shown in Fig. 2 will allow frequency matching to within a small percentage. The source of the standard frequency will be investigated later. For the time being, such a standard is merely a known-to-be-accurate signal source. While observing the scope face, try various small capacitors of the approximate suggested values (or use a capacitor decade box if one is available) until a circle or ellipse appears on the screen. When that happens, the two audio sources are within one hertz of each other.

Another method may be used for those lacking an oscilloscope. This technique, almost forgotten in amateur circles, is one using audio beats to match frequency. It permits matching to within one hertz, and gives a better result than Lissajous Figures for tones separated by several hertz. The audio beat method involves feeding the standard tone into a loudspeaker and the

This is the Teletype patch (jack) panel with the reed relay assembly shown on the right end of the strip. The relay is enclosed in the coil, which is wrapped in masking tape. The unit is then attached to the printed circuit board referred to in the text.

AFSK generator to be calibrated into another (both through amplifiers, of course). As the generator frequency is adjusted to that of the standard, using trial capacitors or a decade box – as above – audio beats, that is, variations in amplitude, will be heard. When the beat frequency is less than one or two per second, the two audio tones are matched within one hertz.

Since exact frequency tolerance is not needed – it makes little difference to the receiving operator whether your "mark" is 2125.0 Hz or 2126.7 Hz – the audio beat method is perhaps better suited to the newcomer with only a limited audio refer-

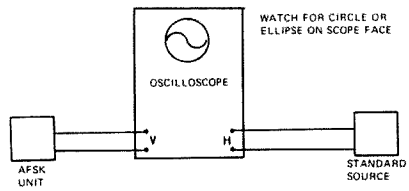

Fig. 2. Simple frequency matching setup.

ence source. At, say, five hertz separation between tones, the oscillographic Lissajous Figure will be a meaningless blur, while audio beats will be present at a rapid rate. Thus, adjusting the tones by the beat method, once slow beats are obtained, the frequency is within fair limits.

Although much has been said so far about the "standard" frequency, details have not yet been given. Such a standard should be capable of supplying the mark frequency, 2125 Hz, and the space frequency, 2975 Hz, at a reasonable level of accuracy, stability, and sine waveform. Perhaps the easiest standard to use is another AFSK generator, known to be accurate. Such a generator could be borrowed from a friend or its signal used over a strong VHF link. Alternatively, a calibrated audio generator could be set up for the 2125 Hz mark and 2975 Hz space tones. A third method is available to the ham who has an operating demodulator. Tune in a strong carrier on the receiver, as from the transmitter's spot function or the 100 kHz crystal calibrator, and adjust the bfo to give the proper tones for Teletype. To calibrate the generator, adjust the standard to produce the tone for space (2975 Hz). Adjust Cs until the AFSK unit produces the correct space frequency, as

measured by either of the frequency matching methods above. Close the switch grounding Cm and move the standard to the mark tone (2125 Hz). Adjust the value of Cm for the correct mark tone. Recheck the space tone to be sure interaction has not changed it. Feed the signal of the AFSK generator into the mike input of your transmitter, adjust the level control for 100% modulation, connect a key at J2 or a mike at J3 (for the CW or phone identification required), and you are on the air.

If you connect this directly to your keyboard contacts you may have some problems. First of all, the generator must be keyed "dry." That is, there can be no current or voltage on the keying line. Second, the contacts used to key must be clean. While not so much of a problem with a keyboard, the rotating contacts of few T-Ds are clean enough to key this circuit without hash. The solution to these problems is to key through a set of contacts separate from the Teletype loop.

For years, the only accomplished way to do this was by a polar relay. Other, spring-returned, mechanical relays differed too much in their make vs. break current to key without bias (changing the length of the 21 msec Teletype pulses). Recently, however, a new device – the magnetic reed relay – has come upon the scene. Literature has described this device as being able to operate upwards of 2000 Hz. If a 2000 Hz signal were fed to the activating coil, the contacts would make and break 4000 times a second. Each actuation would be 0.25 msec long. It appears, therefore, that the relay could operate on the 21 msec Teletype pulses. Such a relay was procured from a local supply house, and a coil wound on the form enclosed with the relay. The coil has several thousands turns of 32-gage wire, and a dc resistance of 45Ω. It readily pulls in on 40 mA, thus the 60 mA local loop current assures positive action.

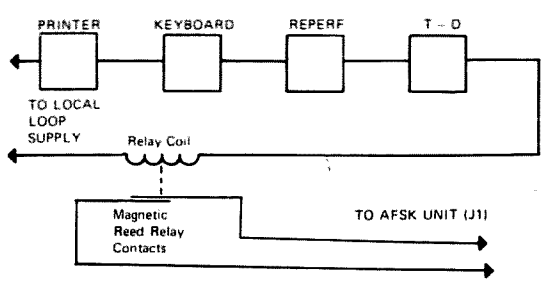

Fig. 3. AFSK keying arrangement installed in loop.

Transmitting tests using the relay to key the low frequency FSK rig showed no detectable bias. The relay was then installed into the loop as shown in Fig. 3. For mounting convenience it was fastened to a small printed circuit board, origin and original function unknown. The magnetic relay is now used for keying both the AFSK and FSK rigs, with excellent results.

Construction techniques are entirely up to the builder. At WA3AJR, the AFSK oscillator is built on a small piece of perf-board and mounted in a minibox with its complement of jacks and switches. The magnetic reed relay, as noted, is attached to a piece of printed circuit board for support, then mounted behind the Teletype patch panel.

The circuit shown here is, to me, a fast and easy way to transmit on VHF Teletype. It is not recommended that the output of this particular AFSK generator be fed to a sideband transmitter to attempt low frequency FSK. The output of this circuit, while a reasonably good sine wave, is not perfect, and some spurious sideband generation may result. The relay keying circuit is applicable to all phases of Teletype, and can be used in preference to a standard polar relay. If reversal of the tones or keying mode is desired – not necessary, but perhaps desirable in some cases – SPDT reed relays are available. The total elimination of a bias supply (needed with a polar relay) and the ability to separate receiver and transmitter from the same frequency and still maintain local copy are easily appreciated.

Several modifications to this circuit are readily apparent. One amateur who built it added an extra transistor as a switch to further isolate the keyboard, instead of the relay. Another built the unit on a printed circuit board. Each, however, has retained the simplicity of the tone generation circuit and discovered the fun in VHF Teletype

Tuning Indicators for SSTV Monitors

For several years I have been experimenting with SSTV and have realized that there is a need for a device to aid in tuning the SSTV signal to provide the correct audio output tones from an SSB receiver. I've developed and tested tuning indicators for SSTV monitors in both solid-state and tube-type designs. The type used with tube model monitors incorporates a 6FG6 light bar indicator, and a light emitting diode (LED) is used with solid-state designed monitors.

Solid-state and tube-type SSTV monitors equipped with tuning indicators are shown in the photograph of Fig. 1. The monitor on the left is a tube-type based on the design by MacDonald (QST, March 1964). The light-bar tuning indicator is located just below the CRT screen. The monitor on the right of the photograph is a solid-state, magnetically deflected design based on a circuit by Make Tallent W6MXV. The LED tuning indicator is installed just below the vertical reset push-button.

Tube-Type Tuning Indicator

The signal diode on the indicator input (point A of the schematic diagram) should

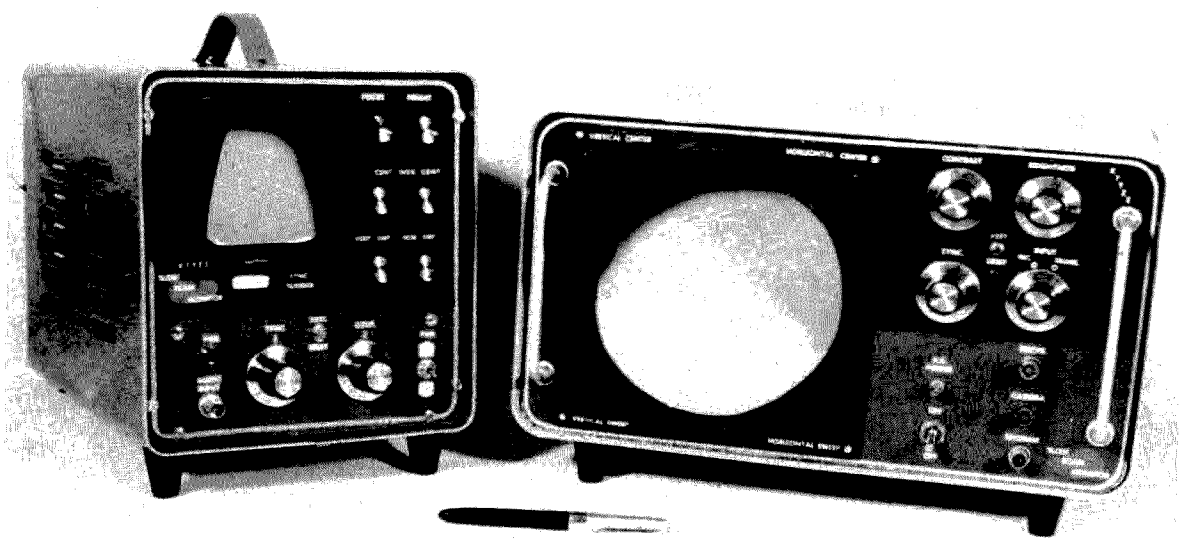

Fig. 1. Tuning indicators for SSTV monitors.

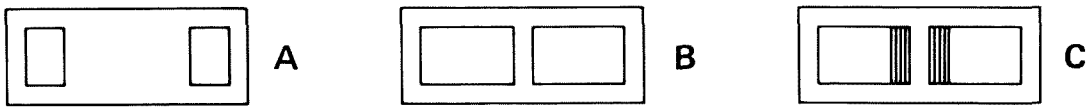

Fig. 2. Tuning indicator displays. The no-signal state is shown in A. B shows presence of a steady 1.2 kHz signal; C is a 15 Hz flickering to indicate that the SYNC signal is in tune.

be connected to the high side of the SYNC gain control (R1 of the MacDonald circuit). High voltage for the indicator is taken from the same voltage as that supplied for the 12AX7 limiter. With a 1200 Hz test signal connected to the input of the monitor, of sufficient level to fully saturate the limiters, the gain control on the tuning indicator is adjusted until the two light bars in the display tube almost close. When a 1200 Hz SSTV SYNC signal is being received, the display on the 6FG6 tube will flicker at a 15 Hz rate. Maximum deflection of the flickering display indicates that carrier reinsertion by the SSB receiver is at the proper frequency for optimum SSTV picture reception. Typical displays as seen on the tuning indicator are shown in Fig. 2.

Figures 3 and 4 are photographs of the tube-type monitor showing the installation of the light-bar SSTV tuning indicator. The small circuit board just below the base of the tuning indicator tube is used to mount the gain control, bypass capacitor and rectifier. The remainder of the components are mounted on the tube socket.

LED Tuning Indicator

The components for this circuit were mounted on the plug-in circuit card containing the limiter and FM detector circuits. The 88 mH toroid and associated parts for the tuning indicator circuit are shown in the photograph of Fig. 5. When the circuit assembly is finished, power is applied to the circuit and a 1200 Hz test signal is connected to the input at point B

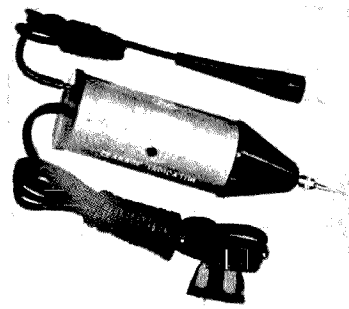
To Troubleshoot **FAST & EASY**



use: Serviset
Model EC
PATENTED
Intro-Price
$29.95 Postpaid

A precision engineered professional quality electronic test instrument. Ideal for field or bench servicing of all types of Communications gear.
CHECKS: sync, sweep, video, audio circuits, high voltage supplies (DC, RF or Pulse), low voltage supplies, coils, capacitors, resistors, tubes, transistors, diodes, transformers, speakers, etc. Will locate trouble to a particular stage, determine defective component and can actually be clamped in circuit to restore circuit operation temporarily in 80% of component or tube defects. Ideal for locating and confirming intermittents.

SPECIFICATIONS:
RF 7 AF Signal Tracer, RF & AF Signal Injector, AC & DC Voltage Indicator 0/60/550/20,000 DC Polarity Indicator 60/550/20,000 volts, Lo ohms 0-5. Hi ohms 0-500k-20 megohms. Test Condensers, .00025-12 mfd., Tests Resistors 2 ohms-20 megohms, 2 Capacitance Sub ranges .01-1 & 4-40 mfd., 3 Resistance Sub ranges 50-500 ohms, 5k-25k, 100k-1 meg.
SERVISET MODEL E-C will out-perform any tester of its size, weight, & price ANYTIME-ANYWHERE.

NEW CT-1
Will allow you to Dynamically test all types of capacitors.

The Model CT-1 features a built-in electronic power supply providing BOTH AC and DC Test Voltages in a special circuit with highly sensitive NEON type leakage indicator. The CT-1 permits quick, accurate testing of condensers for leakage or shorts with actual DC voltage applied and readily indicates intermittent OPEN condensers with AC applied. Self-regulating power supply circuit provides tapered forming current to suit particular requirements of capacitor under test. Special circuit re-forms and polarizes electrolytic and tantalytic capacitors under test. High sensitivity permits determination of condenser dielectric breakdown before leakage causes major shut-down.

ONLY $16.95 ppd.

Capacitance Range: .00025 – 1000 mfd.
Sensitivity: Over 200 MEGOHMS
Dealer Inquiries Invited

IDEAL for: Professionals, Amateur Repair men, Ham Radio Operators, **STUDENTS**, appliance repairmen, etc. Will complement your existing equipment and will outperform other testers costing many times more. **30-Day Unconditional Money Back Guarantee, 90 Day Parts Warranty. ORDER TODAY.**

LEE ELECTRONIC LABS, 88 Evans Street, Watertown, Mass. 02172

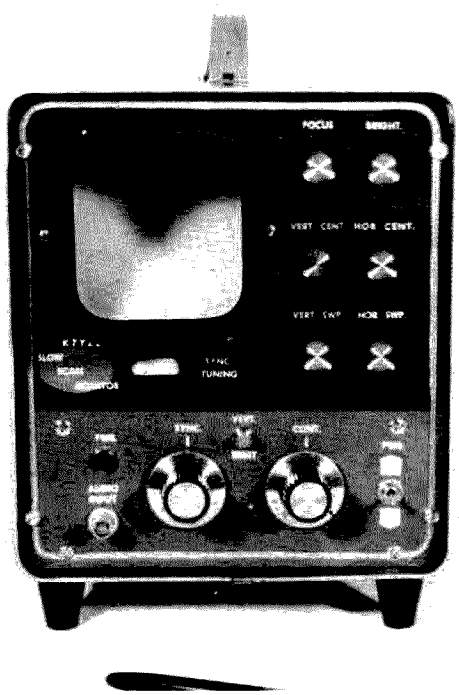


Fig. 4. Tuning indicators for SSTV monitors.

on the schematic (Fig. 6). The capacitor is selected to resonate the 88 mH inductor to 1200 Hz by monitoring the output voltage developed across the diode load resistor with a VTVM.

To install the LED tuning indicator in a solid-state monitor such as the model by W9LUO described in the March 1971 QST, connect input point B to the collector of transistor Q2. A 1200 Hz SSTV SYNC signal will cause the LED to flicker at the 15 Hz rate. The indicator will be dark if the SYNC signal is absent. When the receiver is mistuned to the point that SSTV video or noise is appearing in the tuning indicator, the LED will flicker at a random rate.

From a study of the schematic of the Model 70 Robot SSTV Monitor it looks like the input to the LED SSTV tuning indicator (point B) should be connected to pin number 6 of the integrated circuit U1 709C limiter.

REPEATER CIRCUITS MANUAL

If you're into FM, you'll want to have this incredibly complete manual of FM circuits. You don't have your own repeater yet? Well, you've been thinking of it . . . admit it. Some fellows even have gone so far as to have a repeater in their car so they can extend the range of their hand units!

This book, over 300 pages long, has just about every circuit that you could possibly want. Many of these have been published elsewhere, but many haven't, too. And you can go out of your mind trying to find a circuit when you want it . . . so here they are, all in one handy place!

ONLY **$6.95** ppd.

LET'S REVISE The MORSE CODE

I've just read Ford's article of the same title in the November issue of 73 and it is wonderful, well thought out, logical and should be adopted immediately; also we should end poverty and war. In other words, no matter how good an idea is, if it involves something new or different it is a dirty communistic plot to violently overthrow the status quo.

What we need is a system that will take the present equipment and make it work more efficiently. Now, although I could have thought of this all by myself, if given time, the credit should really go to some other guy. Let me explain. When I bought my TG34 code machine there were four tapes with it and one was a skip tape. A skip tape is one where every letter is sent at the 20 wpm rate but there is about a four second pause between letters so the Novice can say, "What the hell was that?" and have time to think about it before the next letter rushes at him. As Ford points out, code is an audio response phenomenon and letters sent slowly do not sound anything like letters sent fast. But it is just as easy to learn the fast letters as it is to learn the slow letters – in fact I think it is easier.

Now hear this – here is the secret of the Morse code – free. To send code everyone should set his bug or IC keyer to the 20 wpm speed. To send five words per minute you pause between letters to allow time to think, and you wait longer between words for the person copying to take a breath and all this time he is learning what the 20 wpm letters sound like. Believe me, it is easier to receive with this system because the complete letter goes into your mind's shift register very rapidly and you have more time to search your memory before the next letter arrives. It works; you will be astounded at the rapid progress you will make. Try it with the next Novice you work and see for yourself. . . .WB6JNI

MATRIX

Tom Yocom WA0ZHT
1530 Country Club Drive
Marion IA 52302

If you are a regular reader of 73 Magazine, you have undoubtedly noticed that a large number of articles have appeared covering the various aspects of amateur 2 meter FM operation. The intent of these articles has been to entice you to give FM a try. Many people have been involuntarily bitten by the FM bug. I am no exception. I have found a large amount of personal satisfaction in designing and building digital circuits for use in conjunction with a 2 meter repeater. Through this endeavor I have been able to learn about several different fields: Touch-Tone, discrete components, and integrated circuits.

Perhaps one of the more surprising things that happen when you start to investigate a new field is the large number of new techniques you are compelled to investigate and learn. My pursuit of control circuits for an FM repeater has lead me into several textbooks dealing with the subject of switching theory as it applies to the design of digital circuits.

The repeater that I have been working on for the past 6 months consists of a large number of Sylvania TTL integrated circuits that were purchased on the surplus market at a cost of 10 cents per flatpack.

There is more to building a device than removing the components from the original circuit board.

In digital design I have found that one frequently starts with a rather simple block diagram of the device desired and then proceeds to draw the detailed logic diagram consisting of the various *nand* and *nor* gates required to accomplish an objective. It is frequently useful to express some of the relationships mathematically using Boolean algebra. If you have mastered the subject you can then apply simplification rules to the equations to produce a less complicated statement of the problem. This is desirable because as you reduce the complication of the equation, you are in effect reducing the number of devices that will be required in the final circuit you construct. A simplified equation will lead to several benefits which come about as a result of less components:

1. Lower cost
2. Decreased construction time
3. Smaller area through less wiring and interconnection
4. Increased reliability
5. Simplified schematics
6. Lower power consumption

The September 1970 issue of 73 described P. J. Ferrell's digital circuit that was used to automatically generate the CW identification for a repeater located in Seattle, Washington*. His call-letter generator consists of a five-digit ripple counter which is used to control the characters generated. When you design the unit, you are basically saying things like this:

1. I want a dot when the counter equals 0.
2. I want a dash when the counter equals 1.
3. I want a dash when the counter equals 2.
4. I want a space when the counter equals 3.
5. I want a dot when the counter equals 4.
6. I want a space when the counter equals 5.
7. Etc.

If you examine the above statements you will be able to see that what has been specified is the sequence dot dash dash blank dot dash . . . in terms of a sequential counter. The basic logic problem becomes one of specifying when the dots, dashes, and blanks are required as a function of the value existing in the counter. One way is to use a lot of gates or diodes to in effect say, "If the binary pattern in the counter is 1 1 0 1 1 then I want a dash; if the binary pattern is 1 0 1 0 0 then I want a dot." This would imply that you would need a lot of gates with 5 inputs if you wanted to get the job done. When I was faced with this problem, I went to the textbooks and was glad to discover that someone else had already faced the problem and solved it for me!

The original article suggested the use of a Karnaugh map for minimizing the number of diodes required in the read-only diode memory. Karnaugh maps are helpful in many instances, particularly when the number of variables is four or less. Many people find that when there are more than four variables the map becomes rather difficult to understand. Of course, the world does have map experts but what amateurs need is a simpler approach to the

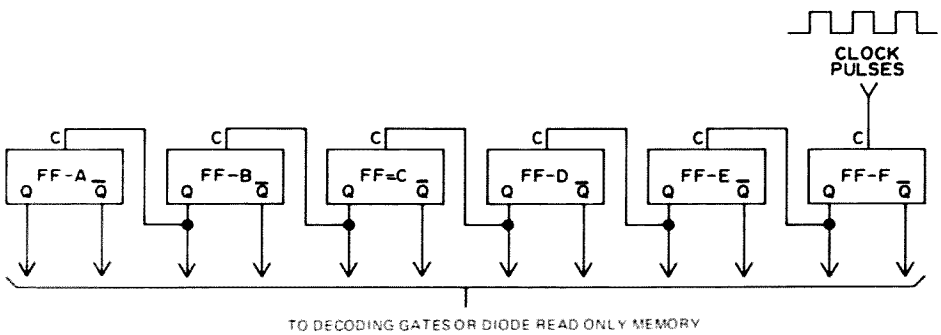

Fig. 2. Ripple counter described in text.

problem of simplification of counter decoders.

The Tabular Method

Several textbooks describe a method that requires a fair amount of clerical work but only a limited amount of real thinking. I chose to use that method. The discussion that follows is aimed at showing you how to apply the "Tabular Method" to simplify counter decoders. (An excellent discussion of the method, with some sophisticated extensions, exists in "Switching Circuits for Engineers," by Mitchell P. Marcus.)

So that you can better understand the relevancy of the Tabular Method, let us analyze the decoding necessary for constructing a digital CW code identifier having a 6-bit counter. Although most amateur calls can be described without resorting to more than 32 different characters (dots, dashes, and blanks), let's generate a fancy message. (Note that *any* message could be generated, e.g., RST 589 IOWA K.)

When the call is to be transmitted, your system will probably cause a push-to-talk relay to be activated. Consequently, it would be nice to begin the message with a blank to give the relay time to pull in. If the identifier is used in a complex system that supplies dial tone to its users, it may also be desirable to have a blank at the end so that the CW does not "run into" the dial tone. If you put these thoughts together, you will have a message that closely resembles the one described in Fig. 1.

Figure 1 contains additional information that will be referred to in different stages of our discussion of the simplification procedure. You should notice at this point that each character that composes the message has been paired with the value that would be in the counter when the character was to be generated. The value of the counter is shown in decimal and also in binary for your conversion convenience.

The zeroes and ones in Fig. 1 represent the binary equivalent of the decimal numbers shown in the "decimal count" column. A zero means that the associated flip-flop is *reset* while a one means that the flip-flop is *set*. (Some manufacturers refer to the outputs as Q and $\overline{Q}$, corresponding to true and false; Q = true = 1 and $\overline{Q}$ = false = 0.) For convenience in referencing the flip-flops that compose the various stages of the counter, the flip-flops are designated as A, B, C, D, E, and F (See Fig. 1). If flip-flop A is in the set, or true, state, we will write the letter A; however, if flip-flop

Fig. 4
Tabular display for blanks.

A is in the reset, or false, state, we will write $\overline{A}$ (read "A not"). Figure 2 shows the simple counter used in our discussion.

You should notice that the binary expression of the count shows that a 6-stage counter is being used. This means that you could have as many as 63 characters in the message (saving the last value of the counter for stopping the sequence). The counter has 64 unique states, 000000 through 111111.

The Tabular Method can be used to help simplify logical states for various applications but if we address our attention just to the CW identifier previously mentioned, then what we want in this case is a simplified statement of when we need dots and when we need blanks (the character generator circuitry produces dashes unless programmed to generate something else). The equations that result from the simplification can be used to specify the gates that must be used if you choose to decode the counter with integrated circuits. Since W7PUG's system used a read-only diode memory, I will address this discussion to that mode of implementation and show you how the Tabular Method will minimize the number of diodes required and produce a wiring map for use in constructing the decoder. For this example I chose a "fancy" message so that the counter would have to be composed of 6 stages rather than only 4 or 5.

Since the circuitry generates dashes automatically, we have to generate expressions for only the dots and the blanks. The Tabular Method proceeds as follows:

Expression for Blanks

We begin by extracting from Fig. 1 the binary values of the counter corresponding to when we need to have blanks generated. This produces the list of values shown in Fig. 3. As the list is made, we arrange the values so that values with the same number of 1's are grouped together. (The rightmost column in Fig. 1 is used to facilitate this listing.) The values are segmented with broken lines to show those numbers having no 1's, one 1, two 1's, etc. In the case of the blanks you see that there are six basic groups of values.

The method now requires that each of the values in a particular group be compared to each value in the next group. In Fig. 3, this means that 000000 will be compared to 000100 and 001000; 000100 and 001000 will be compared to 000110, 001100, 100001, and 100010. The comparison operation consists of seeing if it is possible to derive the second number from the first number by changing only a single digit position. When 000000 is compared to 000100 you should see that you can get 000100 from 000000 by changing the digit that is in the fourth position from the left. Consequently, these two values give rise to a new value written as 000x00 (The x

shows the position that was changed to make the second value.) This new value is written into a new list shown in Fig. 3 as new-A. Comparing 000000 with 001000 yields a new entry of 00x000 in list new-A.

When a value is used in one of the comparing operations, and an entry is made in a new list, the original values are checked off. You will note that Fig. 3 shows that all but two of the original values were used in this combining operation. Each time a new group of numbers are used as "the first number," a separating line is drawn in the new list. Additional new lists are made until no further combinations can be made. Figure 3 shows the complete set of lists for the analysis of blanks. The values that do not combine are not checked but have been suffixed with an asterisk (*) to indicate that they are to be used in the next step of the simplification.

When the comparisons have been completed, a tabular display such as that shown in Fig. 4 is prepared. The column headings consist of the original counter values that were supposed to produce blanks. A row is added for each value that was suffixed with an asterisk when the comparisons were made. For each of the values shown to the left of a row, we now make an examination to determine the original terms which can be "generated" from the terms identifying the rows. The "generation" consists of

Rule 1 . . . A column, a, can be eliminated from the table if it has checks in every row that some other column, b, has checks. (The subset is saved.)

Rule 2 . . . . A column, a, can be eliminated if it has checks in the same rows as another column, b. (Given two identical columns, one can be eliminated.)

Rule 3 . . . . A row, z, can be eliminated if some other row, y, has checks in every column that z has, AND the number of 0's and 1's in z is equal to or greater than the number of 0's and 1's in y.

Fig. 5. Simplification rules.

replacing the x or x's with both 0 and 1 and then checking off the original terms created. For example, if we take the first row, with 0001x0 we can generate 000100 by substituting 0 for x and we can generate 000110 by substituting 1 for x.

We now place check marks beneath the original terms generated; 000100 and 000110. Applying the same process to an entry such as 00xx00 would produce these original terms: 000000, 001000, 000100,

Fig. 6. Tabular display for blanks after application of reduction rules.

and 001100. The columns corresponding to each of these original values has a check mark opposite 00xx00. If the term contains no x's, for example 011010, then you place a check mark in only one column. When all of the check marks are in place, the table is ready to be simplified by the application of a few simple rules. Figure 4 shows the table with all of the check marks entered properly.

Figure 5 lists the rules that are applied to the table to perform the actual reduction. Let's apply these rules to Fig. 4 and produce the slightly modified form shown in Fig. 6.

For ease of identification, the columns in Figs. 4 and 6 have been labeled with letters of the alphabet. Rule 1 can be applied to columns L and N thereby eliminating column L. Rule 1 can be applied to columns G and K thereby eliminating column K. Rule 1 can be applied to columns A and B, thus eliminating column B. Rule 2 can be applied to columns A, E and C, thereby eliminating columns C and E.

Figure 6 shows with shading the columns that have been removed from the table. The object of this last step is *hopefully* to eliminate rows in the table. In this particular case, no rows were eliminated. Had rows been eliminated, the corresponding terms would be dropped during the next step of our simplification.

The final step in the simplification is to write a statement for the quantity of interest. This simplification was for blanks so we will write a statement which combines the terms opposite rows that were *not* eliminated from the table. The result that we get is as follows:

BLANKS = 001x0 or 00011x or 1000x1 or 10001x or 00x111 or x00111 or 0x1111 or 00xx00 or 010101 or 011010

You should recall that the binary values correspond to the state of the flip-flops A, B, C, D, E, and F. We can thus rewrite the statement by replacing the 0's and 1's with the appropriate flip-flop designator and simply dropping the x's. Doing this, 0001x0 becomes $\overline{A}\ \overline{B}\ \overline{C}\ D\ \overline{F}$. The resulting equation for blanks is thus:

	New-A	New-B
000010	00001x*	0x1x01*
------	------	0x1x01
000011	00x101*	011x0x*
000101	x00101*	011x0x
001001	001x01	
011000	0x1001	
------	01100x	
001101	011x00	
011001	------	
011100	0x1101	
100101	0110x1*	
------	011x01	
011011	01110x	
011101	0111x0*	
011110		

Fig. 7. Values and reduction for dots.

BLANKS = $\overline{ABCD}\overline{F}$ or $\overline{ABC}DE$ or $A\overline{BCD}F$ or $A\overline{BCD}E$ or $\overline{AB}DEF$ or $\overline{BC}DEF$ or $A\overline{BC}EF$ or $\overline{A}CDEF$ or $\overline{ABE}F$ or $\overline{A}BC\overline{D}\overline{E}F$ or $\overline{A}BC\overline{D}EF$

In order to implement this equation, one diode will be required for each of the *or*'s for a total of 10 diodes. For each of the terms in the equation, there will be one diode per flip-flop named. Thus $\overline{ABCD}\overline{F}$ will require the use of 5 diodes. There will thus be 56 diodes for the terms and 10 for the *or*'s for a total of 66 diodes. If we had not simplified, there would have been one diode for each value of the counter (14) plus 6 diodes for each value (6 x 14 = 84) or a total of 84 + 14 = 98 diodes. Application of the Tabular Method has thus reduced the number of diodes by approximately 30% – a 30% savings in parts and wiring! The savings that you will realize varies with the complexity of the message.

Expression for Dots

To be sure that you understand the simplification method, let's apply the technique to the values for dots.

Figure 7 shows the binary values that have been removed from Fig. 1 and listed in groups based upon the number of 1's in the values. You will notice that this time we have only 4 groups of values. As in the

DOTS

	A	B	C	D	E	F	G	H	I	J	K	L
	000010	000011	000101	001001	011000	001101	011001	011100	100101	011011	011101	011110
00001x	✓	✓

011x0x					✓		✓	✓			✓	

**ROW HAS BEEN ELIMINATED BY APPLICATION OF RULES

Fig. 8. Tabular display for dots.

previous example, the simplification begins by comparing 000010 to 000011. This comparison yields the entry 00001x in the second table. None of the remaining values in the second group can be derived from 000010 by changing only a single digit. The simplification continues by comparing all of the values in the second group to the values in the third group. These comparisons generate the new values 00x101, x00101, etc. In this case, by the time all of the group comparisons have been made, all of the original values have been used at least once and are therefore suffixed with a check mark. The values in the new table (new-A in Fig. 7) are then compared and used to generate new values when possible. You should note that when values involving x's are compared, it is necessary that the two values contain x's in the same positions *before* you check to see if the second value can be derived from the first value by changing a single zero or one. Figure 7 shows that the final result consists of 7 terms with asterisks. The next step is to construct the tabular display of the original values and the asterisked values derived from the comparisons. Figure 8 shows such a table.

The next step is to place a check mark in the column or columns corresponding to the original values that can be derived from the asterisked terms. Figure 8 shows the completed table. Once again we must now apply the three rules shown in Fig. 5 to check marks in the tabular display.

Rule 1 can be applied to columns C and I thereby eliminating column C. Rule 1 can be applied to columns D and F thereby eliminating column F. Rule 1 can be applied to columns E, G, H, and K thereby eliminating columns G, H, and K. Finally, rule 2 can be applied to columns A and B thereby eliminating column A. We can now write a statement for dots in terms of the asterisked terms that still have at least 1 check mark in their row. The statement is:

DOTS = 00001x or x00101 or 0110x1 or 0111x0 or 0x1x01 or 011x0x

The statement is next written in terms of the flip-flop designators previously defined (A, B, C, . . .).

DOTS = $\overline{A}BC\overline{D}E$ or $\overline{B}C\overline{D}\overline{E}F$ or $\overline{A}BC\overline{D}F$ or $\overline{A}BCD\overline{F}$ or $\overline{A}C\overline{E}F$ or $\overline{A}BC\overline{E}$

As in the case for the blanks, one diode will be required for each term to be *or*ed

	WITHOUT SIMPLIFICATION	WITH SIMPLIFICATION	REDUCTION
BLANKS	98	66	30%
DOTS	84	34	60%
TOTAL	182	100	45%

Fig. 9. Diode count.

plus one diode will be required for each flip-flop mentioned in each term. The decoding for the dots will therefore require 6 + 28 = 34 diodes. Without simplification, the decoding would have required 84 diodes (12 + 72). Notice again that the

	FF-A	FF-B	FF-C	FF-D	FF-E	FF-F
00001X	0	0	0	0	1	X
X00101	X	0	0	1	0	1
0110X1	0	1	1	0	X	1
0111X0	0	1	1	1	X	0
0X1X01	0	X	1	X	0	1
011X0X	0	1	1	X	0	X

Fig. 10. Wiring map for dots

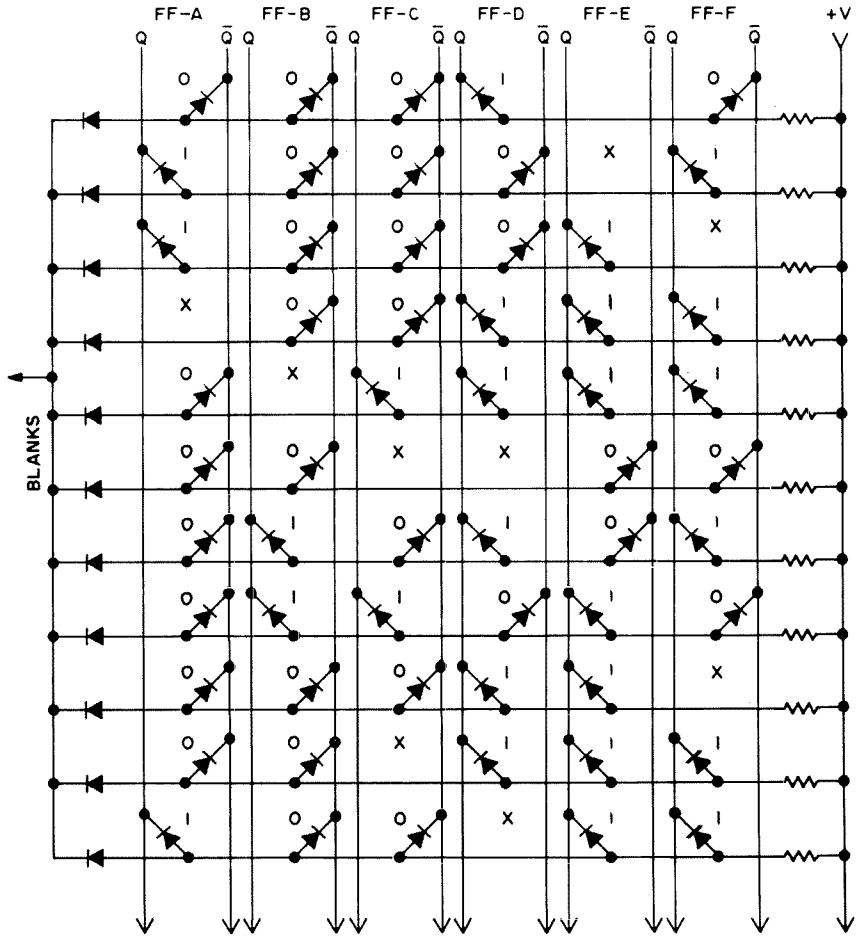

Fig. 11. Wiring map for blanks.

simpliciation has been well worth the effort!

If we take a look at the total problem we see that simplification has been very worthwhile. Figure 9 shows the diode count with and without simplification.

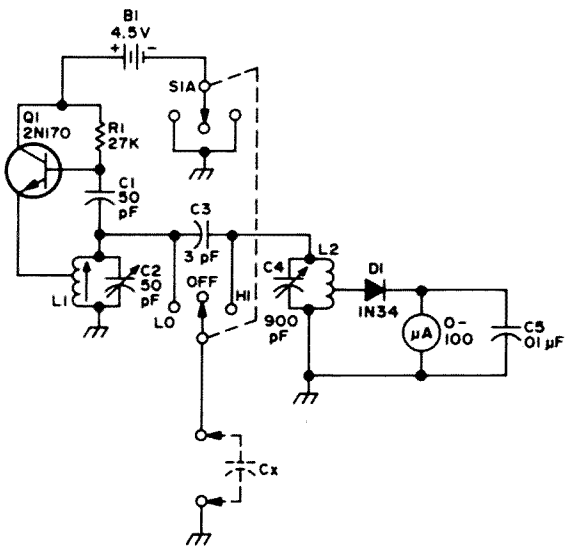
To complete our discussion, let us address ourselves to the proper interpretation of the equations as they apply to the actual wiring of the read-only diode memory. It is helpful to construct a "map" that will help you find your way around the wiring details.

Figure 10 is the wiring map for dots. Across the top of the map you will see the flip-flop designators. The various rows correspond to the individual terms that are in the reduced equation. Take an equation such as:

DOTS = 00001x or x00101 or 0110x1 or 0111x0 or 0x1x01 or 011x0x

For each of the terms, enter one row into the map. The 0's represent a diode connected to the false output of the flip-flop while the 1's represent a diode connected to the true output of the flip-flop. Where there are X's, no diodes are required. The map can thus be described by simply displaying the terms of the equation in a list! Such a wiring map is useful when you start to construct your decoder. Figure 11 shows the map with the diode wiring schematic superimposed to help you see the map's usefulness for wiring the blanks decoder.

In this discussion I have introduced you to a method of simplification that is not difficult and yet is flexible enough to allow easy simplification of count registers having many digits.



As a final testament to the method's utility, I have applied the principles described herein to my 5-digit counter and have an identifier running that flawlessly generates my call! Why not build yourself an identifier? You might include several decoders to generate signal reports, ARRL section, etc. for field day use!

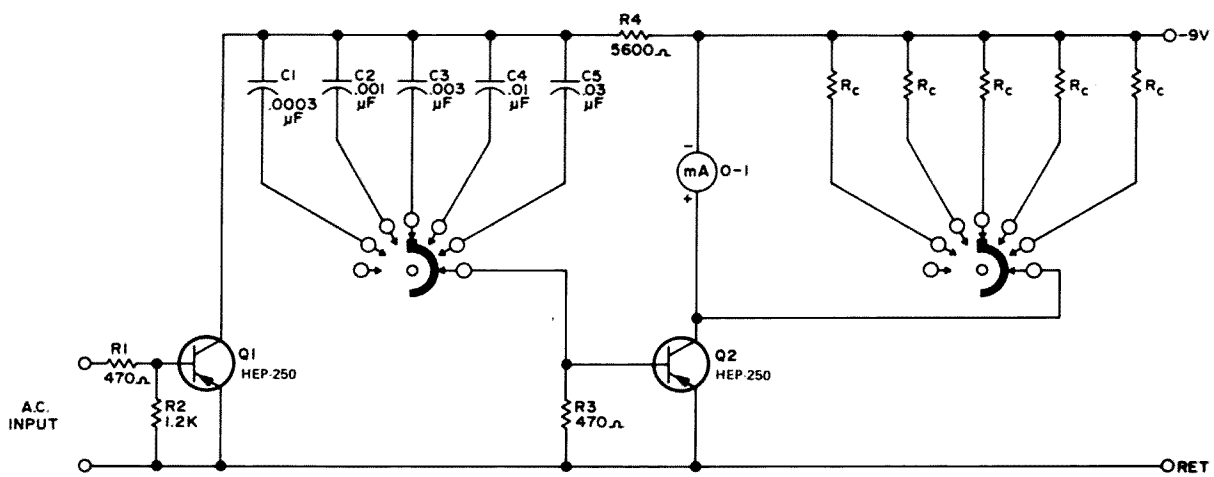
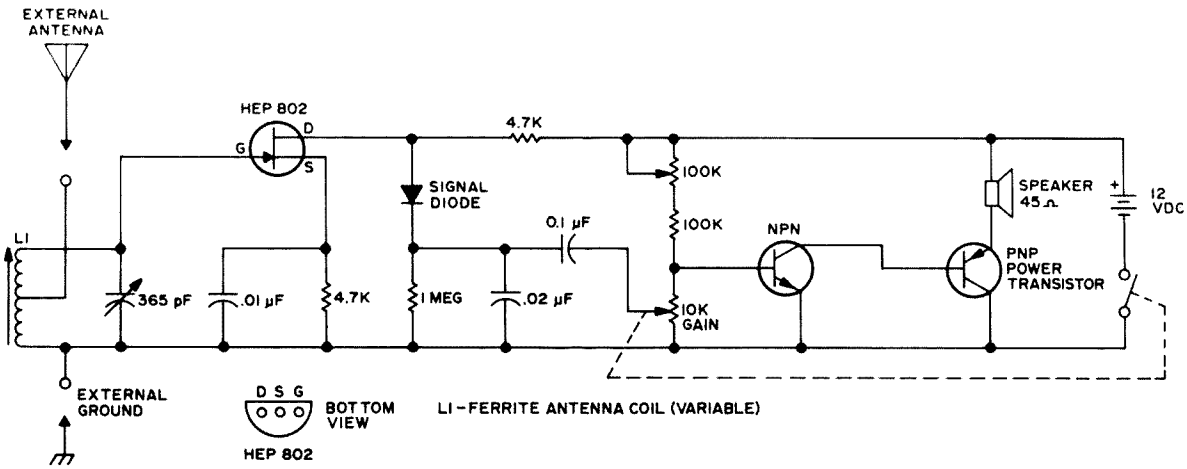
CIRCUITS, CIRCUITS, CIRCUITS...

The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.

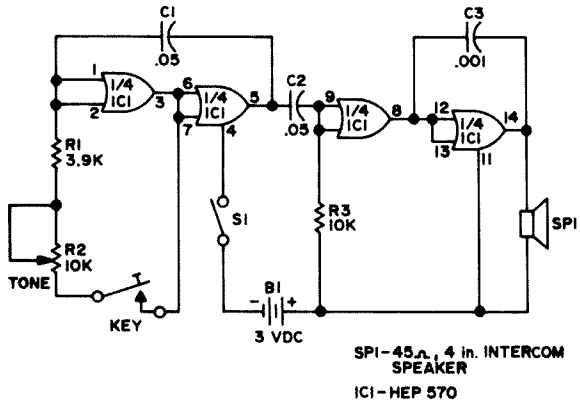
Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.



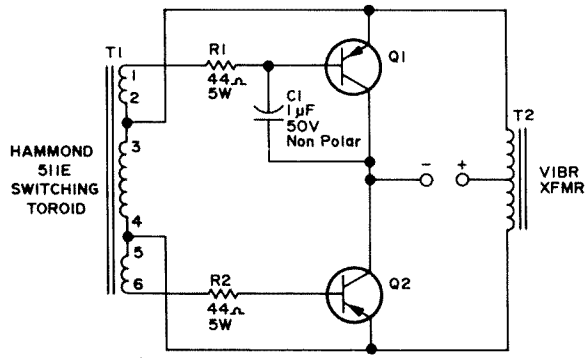
Capacity Meter. From Dec. 60 73 p15. L1-C2 and L2-C4 should tune to the same frequency, around 1450 kHz. Calibrate by setting C4 near max and mark that "zero." Peak meter with C2, which is zero adjustment. Calibrate with known capacities and mark C4 dial.



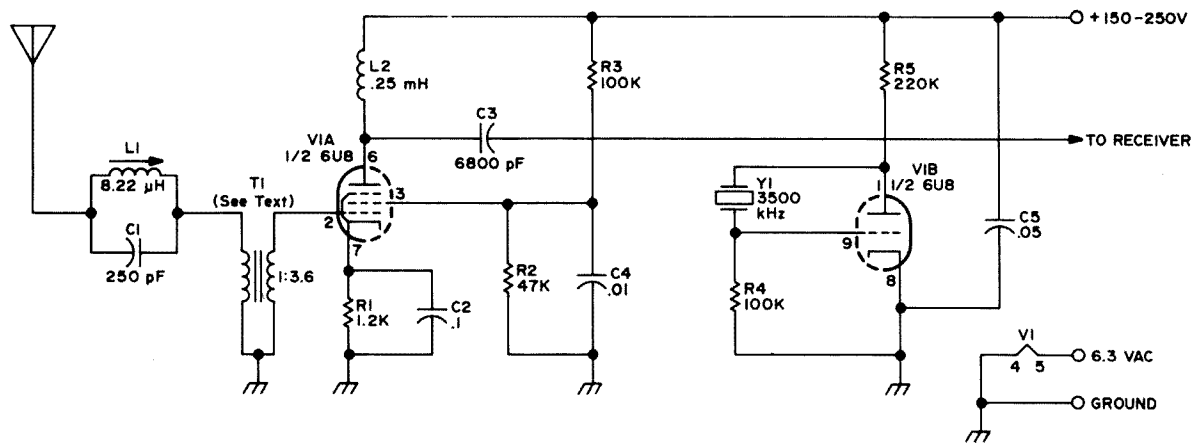
VK2AAR Wire Antenna



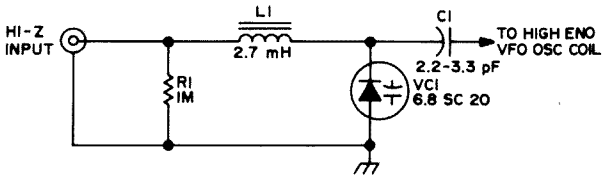
Works best on 20m, with higher (but not unreasonable) swr on 40 & 80m (3:1). Note bottom section drags sides in about 15°, a critical dimension that may require experimenting. Antenna courtesy Amateur Radio July 71. Wireless Institute of Australia, Box 36, East Melbourne, Vic. 3002.



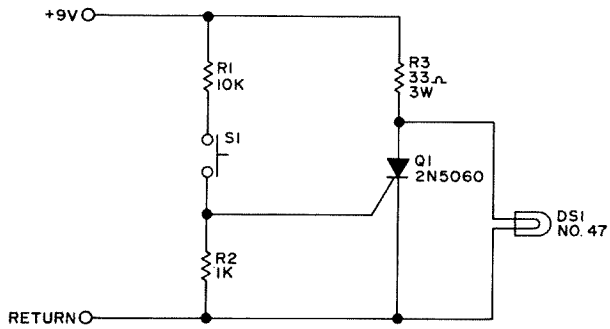
From 73 Magazine, November 1960, this schematic gives the basics for a simple, inexpensive audio frequency meter. For the cheapie special version, omit all switches and components associated with them. Connect a capacitor of proper value in place of S1A. Ranges are: OFF, 30 kHz, 10 kHz, 3 kHz, 1 kHz, and 300 Hz. Meter is 0–1 mA.



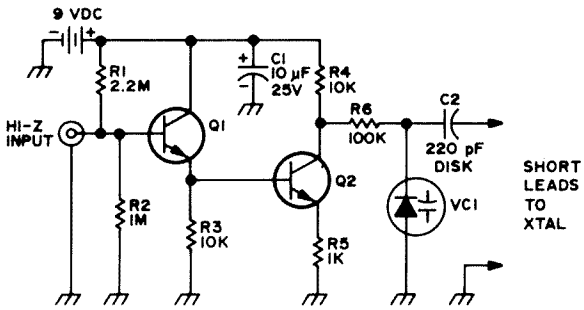
Three transistor radio (AM). Adjust R4 so voltage across speaker is 1/2 supply voltage. Works surprisingly well. Circuit courtesy Calectro Handbook. L1 is a ferrite antenna coil (variable) (Calectro #D1-841); Q2 is an NPN transistor (Calectro #K4-506); Q3 is a power PNP (Calectro #K4-521); D1 is a signal diode (Calectro #A1-227).



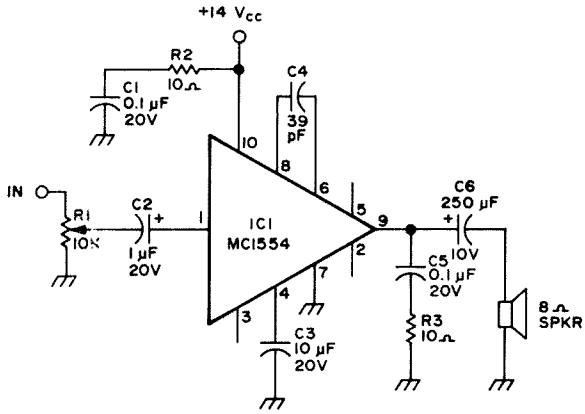
Code practice oscillator using one IC, loud. Intercom speaker may be replaced with a regular 4–8Ω speaker if a transformer is used to match the impedance down from 50Ω to 4Ω. Circuit is from Motorola HMA-36, Radio Amateur's IC Projects, available free from Motorola, Dept. 73, Box 20924, Phoenix AZ 85034.



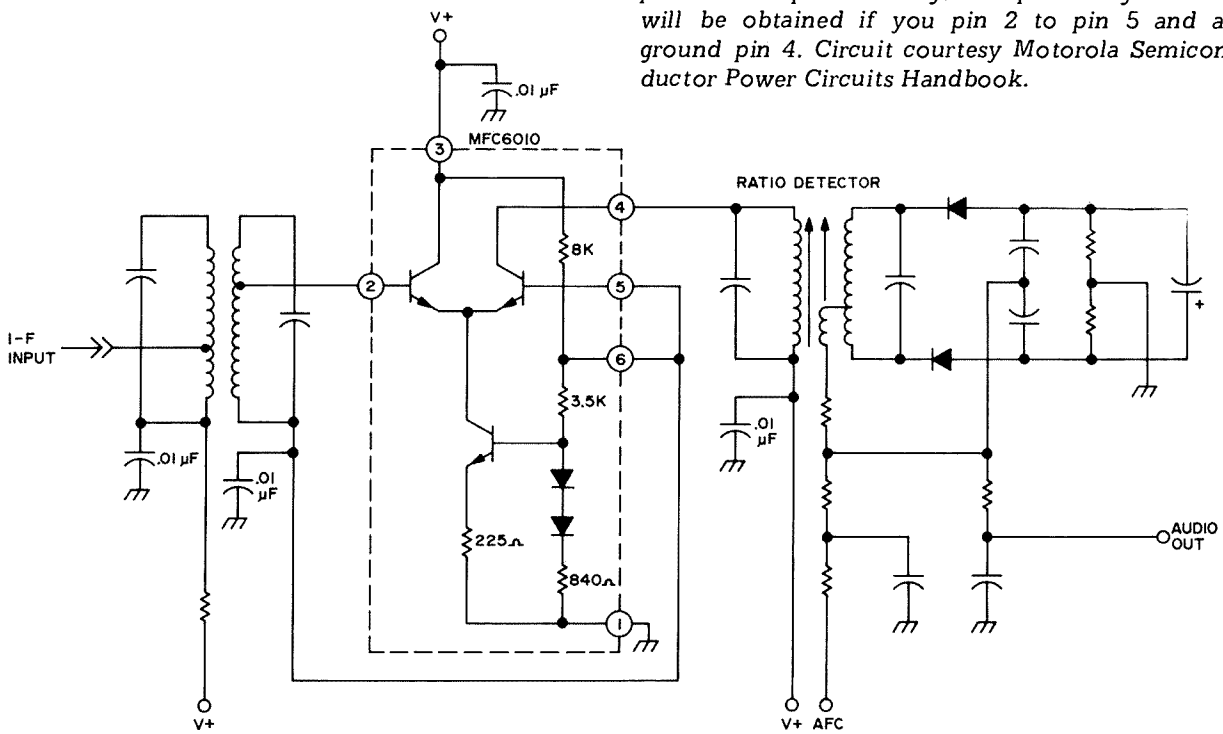
A transistor power supply for a vibrator-powered mobile rig. Called a "Plug-In Solid-State Vibrator Eliminator" by its designer, Vern Epp, it first appeared in FM Magazine, *and is reprinted from* The Best of FM, *available from Radio Bookshop, Peterborough NH 03458, for $4.95.*



VLF converter, tuning 10 to 30 kHz. I-f is at the low end of the 80 meter band. From an article in 73 Magazine, July 1961.



This varactor modulator will put your vfo-operated AM transmitter on FM in ten minutes. Assemble it on a standard three-terminal phenolic tiestrip and tuck it into a corner of your chassis. Both this modification and the one below for crystal controlled rigs should be driven with a high output, high impedance crystal or ceramic mike.



Interrupted-Power Indicator. Circuit courtesy Motorola Semiconductor Power Circuits Manual.

Use this device to put your crystal-controlled AM rig on FM. Both this schematic and the one above are from the 73 Inc. book, The Best of FM, *reprints from the now defunct* FM Magazine.

One watt audio amplifier using one IC. For a gain of 10 leave pins 2 & 4 open and ac ground pin 5 with the 10 µF capacitor. For a gain of 18 leave pins 2 & 5 open and ac ground pin 4. A gain of 36 will be obtained if you pin 2 to pin 5 and ac ground pin 4. Circuit courtesy Motorola Semiconductor Power Circuits Handbook.

10.7 MHz limiting amplifier, using the Motorola MFC6010, a monolithic silicon IC especially designed for 10.7 MHz i-f applications. Typical application schematic courtesy of Motorola Functional Circuits product bulletin.

Making Your Ads Pay

While the larger manufacturers have the budget to pay an ad agency the $100 or so it costs to make up a page ad for a ham magazine, most smaller companies find this prohibitive and wonder what they can do to get the job done for less.

We make up ads for about half of our advertisers and it costs them very little for this extra service. We go that extra mile to make 73 a better advertising medium.

STEP ONE. Throw the engineers out of the art department and keep them out. Sit yourself down in the chair of a user of your product and make a list of the many ways in which your product provides advantages to the user. . .the user, not the engineer. The engineer thinks in terms of the bandwidth of a receiver, the user in terms of only one signal coming through the receiver. What are the benefits, not what are the specs. Oh, you can list the specs too, but these are NOT the selling points.

STEP TWO. In laying out the ad you should keep in mind that you need some sort of "grabber" to make sure that your ad, once seen, is actually read. VW does this with a big picture and a clever caption. Perhaps a picture will do it for you. Or maybe you can think up a good one-liner. Every ad in 73 is seen by every reader, but many go unread because they don't grab attention. Your ad is wasted if it isn't read, obviously.

Work your selling points into the copy and don't be afraid of running all the copy you need to get your point across. Once you have the attention of the reader you want to be sure that he understands why he cannot go another week without buying your unit, why he will have so much fun with it is worth all the problems he may have in getting it by the wife.

A professional picture of the product is extremely important. You're going to need that for spec sheets, brochures, etc., so you should get a good commercial photographer to do the job right for you. We can, if you are short of time, shoot a workable picture with our giant copy camera, but we don't have the facilities to do much more than a good front panel shot.

STEP THREE. Send a sketch of your ad along with the typewritten copy to 73. Include the photograph and any ink drawings or special artwork for the company name, cartoons, etc. This is due in our hands before the tenth of the month if it is to be sure and make the next published issue.

STEP FOUR. In a few days you will receive proofs of your ad as set up by the 73 Art Department. Make sure that everything is as you want it. Make changes sparingly at this time as there will be no further opportunity for checking a proof before publication.

STEP FIVE. As soon as the magazine is out with your ad in it you will receive a copy by first class mail. A few days later the orders will start coming in and then your problem is keeping up with business.

And what will your ad cost you to make? Most full page ads can be made up for less that $50, if there aren't too many pictures or reams of real small type. Our business is selling advertising and magazines, not making up ads. We charge only our costs on ad makeup, so there is no way to get an ad made up more reasonably unless you have the typesetting, headliner, artists, and photo lab needed available.

Send your ads to Aline Coutu, 73 Magazine, Peterborough, N.H. 03458 and get ready to start filling orders.

The Makings of a Modern Day Receiver

There was once a time – and when I first became a ham there were still a few oldtimers who could remember it – when the ham radio operator was, in fact as well as in name, an amateur of radio. His station was more than a mere investment of dollars and cents. It was the testimony of his skill. Rather than take the coward's way out, those hardy hams of yore built their rigs – from the ground up.

It's possible that I'm being a trifle unjust. Equipment has, since then, become far more complex, and construction techniques today require a costly array of tools and test equipment. Nonetheless, I feel that a ham isn't truly an amateur of radio unless he at least knows what's happening inside his rig. To the ham whose daily bread is earned in the electronics trade, such knowledge is a reality; but to the rest of the amateur world a twentieth-century receiver is nothing less than a magic box of mystery.

Now, it's a pretty safe assumption that even the Novice understands the operation of a basic superheterodyne. But what about the expensive complicated receivers now being advertised for the ham of today? Triple conversion, synthesizers, tuned i-f, product detectors, and other terrifying names go round and round in the head of a poor Novice struggling to comprehend the wiles and windings of the engineering marvel he just went hopelessly into debt to acquire. Oh, for the good old days when a guy could sit down and build an oscillator, an amplifier, or a mixer and not bother himself with such complexity.

Frankly, today's receiver still uses the same principles developed back in the dark ages when the ARRL vehemently objected to the use of the "new" superheterodyne. The block diagram shows a typical scheme of the up-to-date receiver. At first glance, it looks a little frightening, but it really isn't that bad if you just take one part at a time.

To most homebrew artists, there's nothing really too mysterious about a crystal-controlled converter, in which a whole band is converted to a range that can be covered more readily by whatever receiver may be available. Looking at the first part of the block diagram of the receiver, we

find a broadband rf amplifier and mixer. If we ignore the fact that the local signal is coming from a synthesizer, and imagine it to be the output of a crystal oscillator, we have a block diagram of a typical crystal-controlled converter.

Taking a look now at the remainder of the receiver, except for the synthesizer, we have a dual-conversion receiver covering 9.0 to 9.5 MHz. The purpose of dual conversion is to combine the advantages of a high i-f with those of a low i-f. When a high i-f is used, image signal frequencies are so far removed from the desired signal frequency they are eliminated altogether. The disadvantage of a high i-f is that high selectivity is much more difficult to achieve. Bandwidth is a direct function of Q and frequency. If the Q of a tuned circuit is held constant while its frequency is varied, the bandwidth will be narrowest at the lowest frequency. For a really selective receiver, a low i-f is required. However, when the i-f is low, it is harder to reject image signals because they are closer to the desired signal.

The answer is two conversions. The first uses a high i-f, which gets rid of images. The first i-f passes through a tuned stage, then it enters a second mixer, where the heterodyne process is repeated all over again. In this case, when the incoming signal is of one frequency, and one frequency only, the local oscillator can be crystal controlled. The new i-f is only 240 kHz. (Some commercially built receivers went as low as 50 kHz.) At a frequency as low as this, a couple of tuned stages can give a bandwidth as low as 3 kHz (or less). Commercial receivers sometimes have the final i-f stages deliberately loaded to open

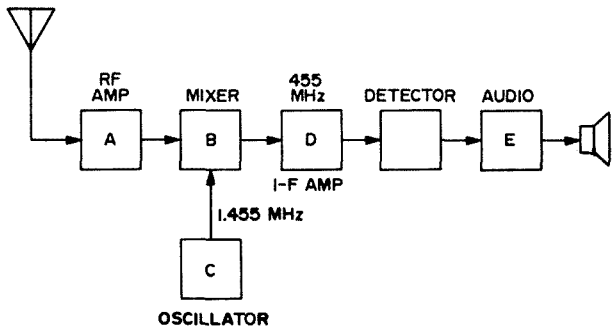

Fig. 1. A basic superheterodyne receiver block diagram.

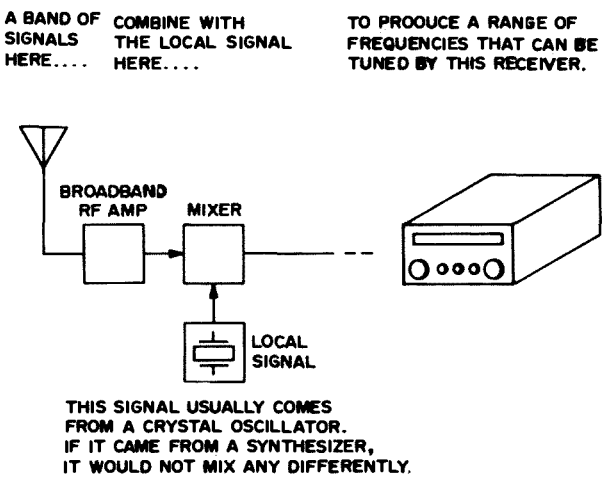

Fig. 2. Basic theory of a crystal-controlled converter. Nothing new to the ham — especially the mobile enthusiast.

up the bandwidth, then they insert a crystal or mechanical filter to give the bandwidth the desired shape.

Having explained the purpose and theory of double conversion, let us turn our attention back to the mixers. Nowadays, the best mixers are exactly the same thing as the balanced modulators used in SSB work. In fact, they *are* modulators and always have been. The advantage of using an SSB modulator is that it gets rid of the two original frequencies entirely, hence a quieter, more efficient mixer. Many of the commercial receivers that use vacuum tubes (and quite a few do) use the type 7360 beam-switching pentode as a mixer.

Some of the better solid-state receivers use a diode-bridge-balanced modulator for their mixers. The input transformer for such a mixer is very critical, however, if the best results are to be realized, so the ham who isn't too proud to use tubes will find the 7360 can't be outdone.

While we're on the subject of mixers and balanced modulators, it is a good time to mention a related circuit, the product detector. A product detector is exactly the same as a mixer or frequency converter circuit, except that the output is audio, rather than rf. The principle is the same as has long been used wherever a bfo signal is mixed with an incoming CW or SSB signal to produce audio. The difference is that the product detector gives no output at all unless both the i-f and the local signal are present. Here again, balanced modulator

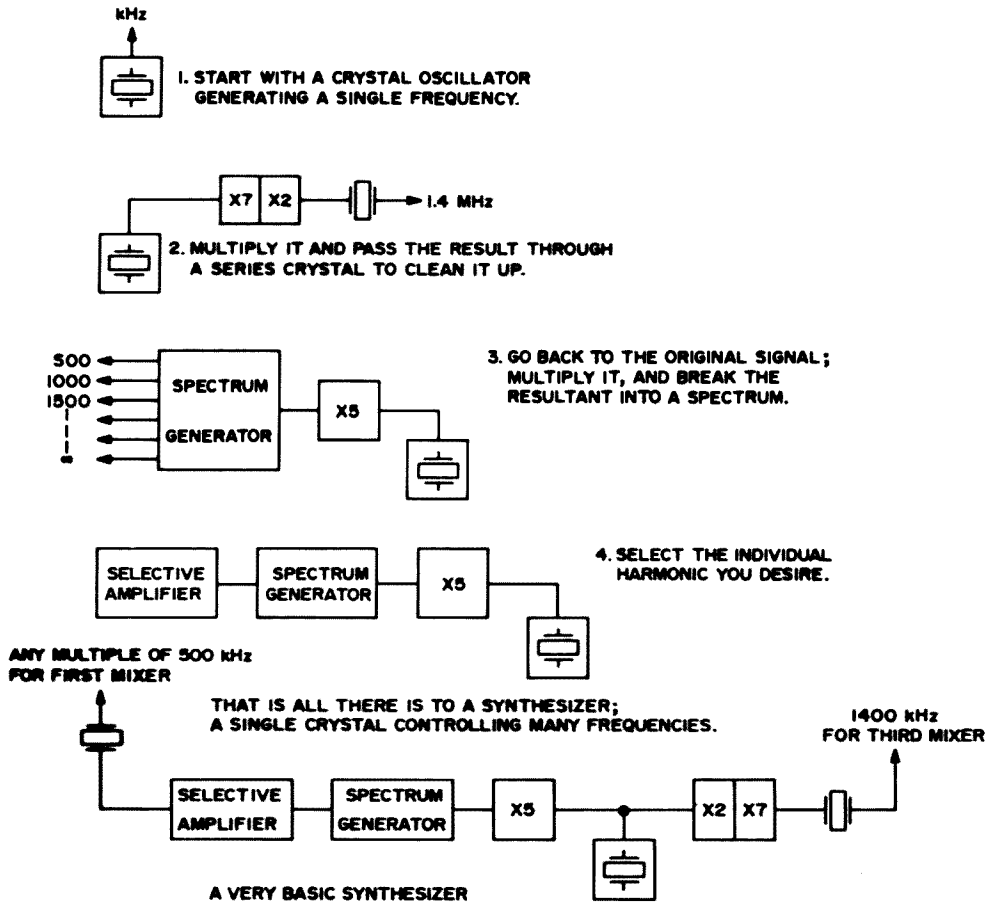

Fig. 3. A very basic synthesizer.

circuits are superior to pentagrid or triode mixers and their solid-state counterparts, since only audio is present in the output. (A pentagrid mixer product detector would have the two rf carriers present in the output, which could produce a little distortion or noise.)

Going back to the mixers, in the original superheterodyne circuit, the local signal came from a vfo. In dual-conversion receivers, a crystal oscillator is used. In the more sophisticated receiver, they use a synthesizer.

A synthesizer is a device that produces a signal at a frequency different from the input signal or signals. A frequency doubler is a simple form of a synthesizer; a mixer is another. Modern receivers use a synthesizer to produce the several frequencies required for the various conversions involved, all being produced from the output of a single crystal oscillator. That way, if the crystal should drift slightly, all conversion frequencies in the receiver would drift at the same time, and by the same percentage. The receiver, then, would continue to hold its calibration. The receiver discussed in this article uses a relatively simple synthesizer. A 100 kHz crystal is multiplied up to 1400 kHz in a basic frequency multiplier.

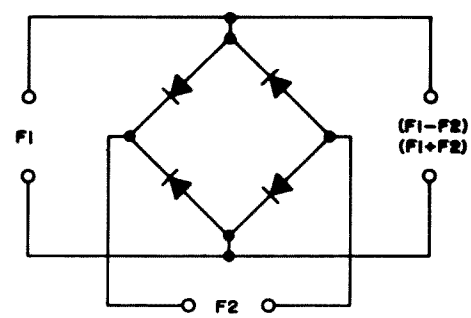

Fig. 4. A diode-bridge-balanced modulator used as a mixer.

The 1400 kHz signal passes through a series crystal and a tuned amplifier after which it is injected into the mixer for the final conversion. The original 100 kHz is also multiplied to 500 kHz and fed into a spectrum generator (the fancy name for a crystal calibrator). The spectrum, which consists of all multiples of 500 kHz, feeds into a selector, which isolates the desired

multiple of 500 kHz, passes it through a crystal filter, amplifies it, and uses it as the local signal for the crystal-controlled converter (the first conversion).

By using exact multiples of 500 kHz for the first conversion, the receiver can select any frequency range 0.5 MHz wide, and convert to the range of the tunable portion 9.0 to 9.5 MHz. Since the tunable portion always tunes over the same frequencies, the receiver has the same bandspread regardless of the band of incoming frequencies.

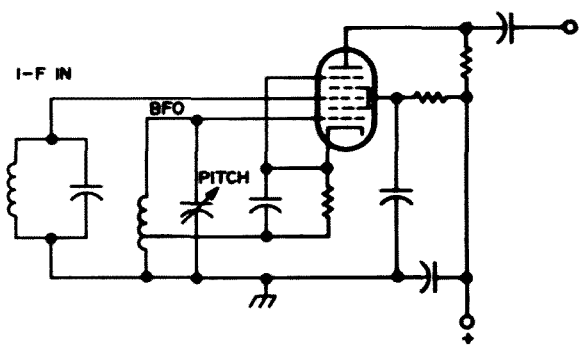

Fig. 5. A mixer circuit with audio output is a product detector.

(Some fancy mechanical manipulation by National engineers provided a dial that always have a 1 kHz per division calibration. The famous HRO 500 uses a spectrum conversion scheme very similar to the one I've described.)

Suddenly, now, the whole puzzle seems to fall together. Incoming signals are mixed with selected frequencies to convert them to the range of 9.0 to 9.5 MHz. This range is then tuned by a dual-conversion, 9.0 to 9.5 MHz receiver. The first and the third conversion come from the same 100 kHz crystal, while a stable vfo tunes the second conversion. Image rejection is achieved in the second conversion, which uses the 1640 kHz i-f, and selectivity is obtained in the final 240 kHz i-f. The receiver is a complex conglomeration of mixers, amplifiers, oscillators, doublers, and spectrum generator, but each part is, in itself, basic.

Several years ago, when financial adversity deprived me of a station receiver, and prevented my buying another, I decided to build one. Being employed, at the time, by National, I was immediately deluged with suggestions and the monster I have just described evolved. I chose to build it using tubes, rather than solid-state, simply because tubes are easier to scrounge. As time passed, my interest waned. Over the past couple of years, it has spent much more time on the shelf than on the bench.

Better times have come, now, and my interest in ham radio has gradually revived. I could easily go out and buy a receiver to get back on the air, but there is something about this project that bears a certain fascination. Perhaps I am a throwback, enslaved by my own stubborn pride. All I know is that I feel I must earn my place in the airwaves by producing that which gets me there. At any rate, come what may, I have completed my receiver, long ago humorously nicknamed the HRO .007 by a wisecracking National engineer and, so far, it works. With just the front end to go, I am determined that, by the time this article sees printer's ink, I'll be on the air once more, and I'll be one of the few hams of today who can truthfully say, "I made it myself."

. . .W2FEZ■

John Schultz, W2EEY/DL

SIMULTANEOUS MULTI-BAND TRANSMISSIONS

Simultaneous transmission on two or more bands has various technical advantages, and is allowed by the FCC under certain conditions. This article illustrates primarily simple combiner networks which will allow simultaneously the operation of two transmitters on different bands into one multiband antenna without transmitter interaction.

Simultaneous transmission of the same modulated signal on two or more amateur bands is permitted by the FCC under certain circumstances as discussed later. Such simultaneous transmission has various advantages in increasing the dependability of reception if a separate receiver is used on at least two of the transmitted frequencies and also an advantage in permitting reception on different single band receivers. The simultaneous transmission technique is often employed by shortwave broadcasters, commercial traffic stations, etc. Usually a separate transmitter and antenna is used for each band. However, for the amateur situation where multiband antennas are available and space for antennas restricted, it would be advantageous to have two transmitters operating on different bands coupled to one antenna for simultaneous operation. The networks which permit the use of transmitters in this manner are called "combiners." Many elaborate forms of such networks have been developed for commercial applications. However, the purpose of this article is to present various simple forms of "combiners" which can be quickly constructed for use with medium power transmitters, particularly where operation on two bands having a harmonic relationship is involved.

Legality of Simultaneous Transmission

It would be nice if one had the equipment available to send out something like a directional CQ or DX CQ simultaneously on several bands in order to have a better chance of making the desired contact. However, such operation, unless some emergency situation is involved, would be considered a waste of spectrum space by the FCC and therefore illegal. The sending of code practice transmissions simultaneously by stations such as W1AW is considered legal because of the large numbers of amateurs served thereby.

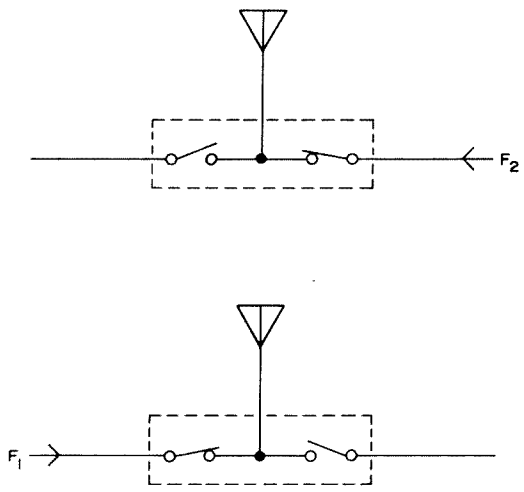

Fig. 1. Representation of the functions of a combiner unit (dotted lines) when either transmitting frequency alone is considered.

Various emergency and other communications that fall under Section 97.91 (b) and (d) of the Commission's Rules can be carried out using simultaneous multiband transmission. There is no hard and fast list of situations that one can specifically cite where such transmission is allowed. However, there are certainly many emergency communications situations and situations that serve the general amateur radio service where the technical advantages of simultaneous transmission is justified to the extent that it will be allowed by the FCC. No special license or permission is required for such operation as long as the basic operator's license is valid for operation on each frequency band used.

Combiner Operation

Fig. 1 illustrates the basic functions which a combiner network must perform. The antenna is assumed to be resonant at frequencies F1 and F2 (either broadband resonance or a trap-type antenna resonant at two different frequencies). When frequency F1 is considered as the output of one transmitter, the combiner network must act so the transmission line from the antenna is directly connected to the transmitter, but the transmission line to the other transmitter appears disconnected. When frequency F2 is considered, the transmission line from the F1 frequency transmitter must appear disconnected from the antenna.

There are a number of practical circuits that can be devised to implement the functions illustrated in **Fig. 1**. **Fig. 2** shows two simple basic approaches – a tuned circuit (A) and a transmission line stub switching arrangement (B). In **Fig. 2A**, F1 is assumed to be lower in frequency than F2. The frequencies in this case must not necessarily be harmonically related. C1 and L1 are chosen so series resonance is produced at F1, thus connecting the F1 transmitter directly to the antenna. C1A and L1 form a parallel resonant circuit at F2, so the F2 frequency cannot flow back into the F1 transmitter. On the other "side" of the combiner, C2 and L2 are series resonant at F2, thus directly connecting the F2 transmitter to the antenna. Since F2 is higher than F1, the L2, C2 circuit will provide a capacitive reactance at F1. This capacitive reactance is utilized together with coil L2A to form a parallel resonant circuit at F1. Thus, the F1 frequency cannot be coupled into the F2

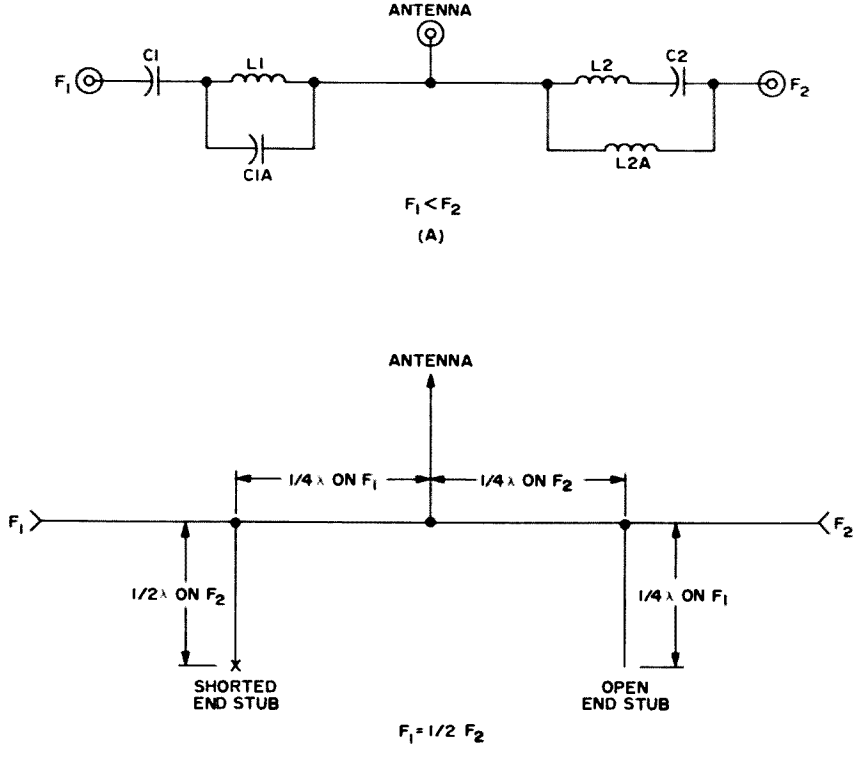

Fig. 2. Basic combiner forms discussed in text. Tuned circuit type (A) and stub type (B).

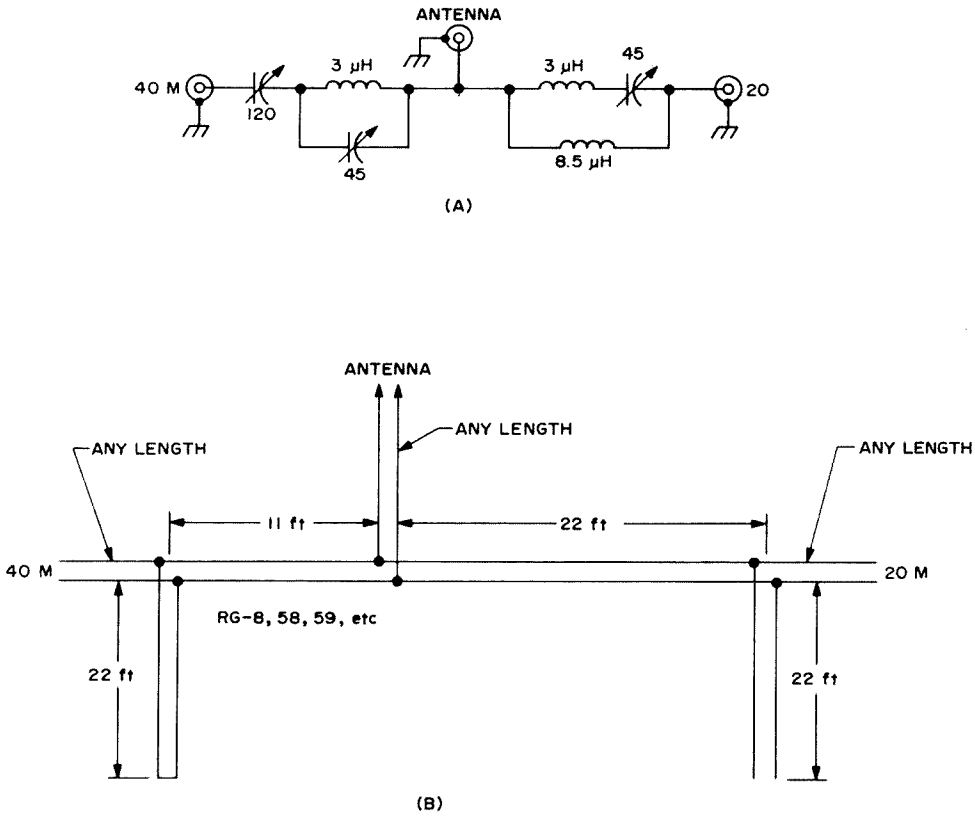

Fig. 3. Practical values for 40/20 meter combiner units. Similar combiners may be constructed for other combinations of amateur bands.

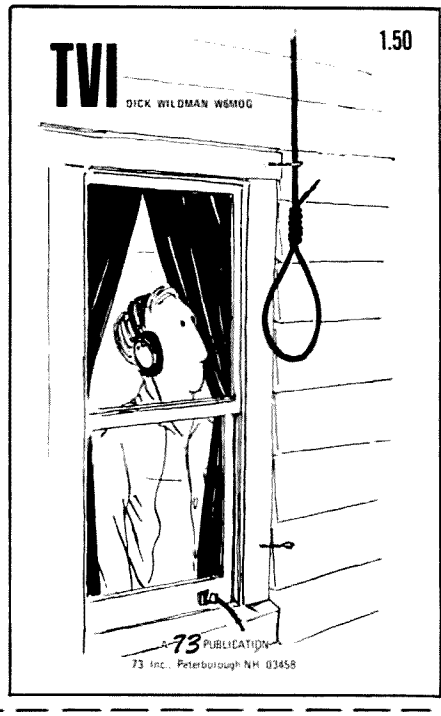
transmitter. The practical construction of such a network requires only the calculation of the component values using standard resonant circuit formulas or can even be done using a LC reactance chart. As high a Q as possible in the tuned circuits is desirable both to reduce losses and to provide maximum coupling isolation between transmitters.

The simple transmission line combiner shown in **Fig. 3(B)** requires that frequency F be one half of that of F2. Normal transmission line (coaxial or balanced type) can be used for the entire construction. The operation can be visualized by first noting that both F1 and F2 transmitters are directly connected to the antenna. However, they are not interconnected to each other. On the F2 "side" of the combiner, the open end stub is ¼λ long at F1. Thus at F1, it reflects a short where it is connected to the transmission line. The length of line between this point and the antenna is also chosen to be ¼λ long at F1. Thus, the short is further reflected at F1 to be an open circuit at the point where the F2 transmitter line meets the antenna. Consequently, F1 cannot couple to the F2 transmitter line. The open end stub on the F2 "side" does not interfere with the F2 frequency because at F2 it is ½λ long and reflects an open circuit across the transmission line. At F2, the transmission line doesn't "know" the stub is there.



A very similar situation exists on the F1 "side" of the combiner. The shorted end stub being ½λ long at F2 reflects a short at the point where it joins the transmission line. From this point to the antenna, the line is chosen to be ¼λ long at F2. Thus, the short is further reflected to be an open circuit at the antenna terminals for F2. F2 energy cannot enter the F1 transmission line. The shorted end stub is ¼λ long at F1, and thus reflects an open circuit across the transmission line at F1. The combiner can be readily constructed from standard transmission line stock by taking into account the velocity factor of the line used

to determine the correct physical line lengths.

Practical Examples

Fig. 3 shows two practical examples of both a tuned circuit and stub type combiner which can be used to couple 20 and 40 meter transmitters to a single antenna for simultaneous transmission. The tuned circuit combiner of **Fig. 3 (A)** is shown as it might be used in a coaxial cable transmission line system of any impedance. The transmission line from each transmitter must, of course, correctly match the antenna line impedance. The combiner serves only as a coupling and isolation network, but not as an impedance matching device. The coils should have as high a Q as possible. For low power transmitters up to a few hundred watts, standard B & W or Air Dux coil stock can be used; but for higher powers, coils made from copper tubing should be used. The coils should also be isolated from each other by mounting them at right angles to each other or using shields between them. With each connector dummy loaded by a small resistor corresponding to the impedance of the transmission line used, a grid-dip meter coupled to the 3 μH coil on the 20 meter "side" of the combiner, the 45 pF capacitor on that "side" is adjusted for circuit resonance on 20 meters. With the grid-dip meter loosely coupled to the 8.5 μH coil, that coil is trimmed for resonance on 40 meters. On the 40 meter "side" of the combiner, the grid-dip meter is loosely coupled to the 3 μH coil. The 120 pF capacitor is adjusted for resonance at the 40 meter operating frequency. The 45 pF capacitor is adjusted for resonance on 20 meters.

The stub type combiner of **Fig. 3 (B)** usually needs no adjustment if the stub lengths are carefully cut to length. The physical lengths shown, for instance, are based upon a velocity factor for the transmission line of .66, and would be correct for such cables as RG-8, RG-58 RG-59, etc. Standard coaxial cable "hardware" such as shown in the photograph can be used to make all the necessary cable interconnections or the cables can be carefully spliced together.

Standard "UHF" type coaxial hardware may be used to make all the necessary interconnections for a stub-type combiner. Shown are PL259 plugs used with a M-358T adapter and a PL258 female adapter in the middle leg.

The schemes shown can be expanded for more than dual-band operation, but extra tuned circuits and stubs would be necessary, resulting in rather complicated networks. If you did want to pursue this approach, it probably would be better to combine two transmitters operating on the lower frequency bands and two transmitters operating on the higher frequency bands in the manner shown. Then the outputs could be combined using a high and low pass filter circuit between transmitter groups for isolation.

No combiner network provides absolutely complete isolation between transmitters. When tuning up the transmitters, each transmitter should be tuned separately for proper loading with the other transmitter inactive. When both transmitters are tried, the slight interaction produced may require some transmitter retuning, but the amount necessary should be minor.

Summary

Used properly and legally for the right purposes, simultaneous multiband transmission can be very useful to better coordinate emergency nets operating on different bands, placing emergency traffic, etc. The proper use of the combiner circuits shown will permit the more useful utilization of the station equipment available which often greatly exceeds the antenna facilities which are available.

The pre-Novice "transmitter" with key.

A PRE-NOVICE TRANSMITTER

For most aspiring hams code practice is the most difficult part of getting the ticket. Copying practice can be quite diversified. There are the records or tapes for learning the characters, then the practice can be supplemented by listening to W1AW or Novices. Sending is generally limited to keying an audio code practice oscillator.

The following idea is not original or unique as the Signal Corps was using it as part of its radio operator training in 1948, when I took the course. As a diversion, and to add interest to our code practice, they had a receiver for two students and a Meissner signal shifter (a variable frequency oscillator) a few feet away. We would close the key and locate the signal on the receiver; then send to each other. We were transmitting less than 10 ft but it was our first time "on the air." It was quite a thrill.

Here is a simple building project and you will have a transmitter of across-the-room capability. The oscillator is an International Crystal Co. OX-LO kit*. Assemble the kit following the instructions for 3000–6000 kHz, as this will permit using 80 meter crystals. The oscillator can be mounted on a piece of wood, but a more professional job can be done by mounting it on a minibox. The OX circuit board has a crystal socket for HC-6/U crystals mounted on it. I mounted a Cinch-Jones 2KM crystal socket on the minibox, then connected it in parallel with the circuit board crystal socket. This arrangement permits using either HC-6/U or FT-243 crystals. All my CW transmitters have a standard ¼ in. phone jack for the key, so I mounted this type of jack on the front of the minibox. Whatever type jack you use be sure it is the open-circuit type as there is no power switch on the oscillator. The key turns it on and off. The battery is made by connecting four size N-cells in series, then taping them in a square. Be sure to tape the top and bottom so the battery can't be

shorted. Connect a 3 in. red wire to the positive terminal and a 5 in. black wire to the negative terminal. If you use a larger minibox, a plastic or metal holder for four penlite cells can be used.

Final Assembly

Make all holes in the minibox before mounting the oscillator. Mount the oscillator board. The mounting screws supplied with the kit are quite long. 4-40 x ¼ screws will be neater. Mount the 2KM crystal socket. Mount the key jack. Clamp the battery in place. Using two pieces of wire 5/8 in., wire the 2KM crystal socket in parallel with the crystal socket on the oscillator board. Solder the red battery lead to the 6V terminal on the copper foil side of the printed circuit board. Solder the black battery lead to the insulated terminal on the key jack. The negative circuit is completed through the key and jack to the minibox, then to the copper foil on the PC board. If you use a painted minibox, be sure to scrape the paint away around the four PC board mounting holes so there will be a good electrical contact from the copper foil to the minibox. This completes the wiring of the "transmitter." Any 80 meter crystal can be used, but it is best to use a Novice band crystal as this will help you get used to this band on your receiver. Do not connect any type of antenna to the oscillator as it is capable of transmitting a signal several miles with an antenna.

If your key is not wired, two-conductor speaker wire is good, as it is light and flexible and one wire is marked. Connect the marked wire (it may have a tracer stripe on the insulation or one wire may be tinned and the other copper) to the key frame terminal. Connect the other wire to the insulated key terminal. Connect the marked wire to the phone jack outside or barrel terminal. Connect the unmarked wire to the phone jack tip terminal. If your key has a shorting bar be sure it is open.

Now is a good time to adjust the key. Adjust the pivot bearings so the key points are aligned; the bearings should be adjusted so there is no play or bind. Adjust the point gap so a piece of postal card will just pass through. The tension adjustment is for

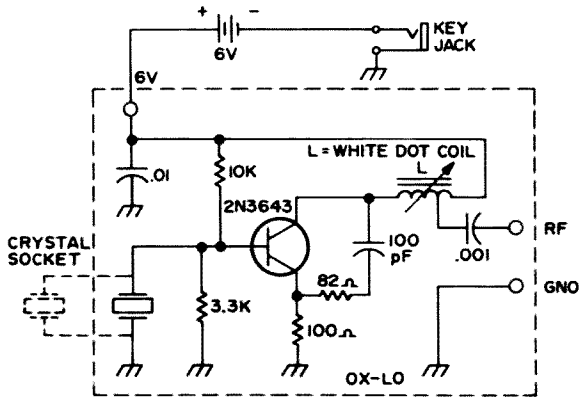

Fig. 1. OX-LO kit has all parts shown inside dotted line. OX-LO kit ($2.95) available from International Crystal Manufacturing Co., Inc., 10 North Lee, Oklahoma City OK 73102.

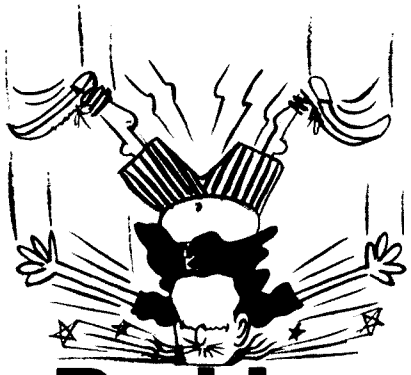

the individual fist. It should not be weak enough so your hand relaxed on the key will close it. Lightly grip the edge of the key knob with the thumb and large finger. Rest the index finger on the knob. Raise and lower your wrist to send. You cannot send with your fingers, as they will tire in a few minutes.

Connect 3–4 ft of wire to your receiver antenna terminal and turn it on. When the receiver is warmed up, close the transmitter key and tune the signal on your receiver. You are now ready for some real code practice. The short antenna on your receiver may give you some background QRM. This is good, as you will have it when you are operating as a Novice.

If you are practicing with a friend and each of you has a transmitter, use crystals of the same frequency so you don't have to keep retuning the receiver. If you have only one transmitter, connect the keys in parallel. Connect a two-conductor wire from the two terminals on one key to the two terminals on the other key.

I think you will enjoy this method of code practice. It is as real as you can get without a license. You will find the little transmitter convenient for additional practice after you get your license, too. You may want to add the International Crystal PAX-1 transistor rf power amplifier module and have a QRP transmitter for on-the-air use.

The Problem of Inversions

The designation of any SSB signal as either "upper" or "lower" is simply an indication of the *position* it holds, frequency-wise, with respect to its reference frequency, which is that which the carrier would occupy if it weren't suppressed. This position, due to the nature of sidebands themselves, determines the characteristics which an individual sideband will possess.

The term "inversion," however, denotes a *change* of the sideband signal from its original to the *opposite* position, which change necessarily results in the signal's acquiring opposite characteristics as well. Accordingly, where no such change in the sideband signal has taken place, the signal, whether it be upper or lower sideband, cannot properly be considered as representing an inversion.

To get along, then, into this problem of inversions, let's go directly to the area where this problem arises: the mixer stage of our SSB rig. While the intended function of this stage is simply to convert the *frequency* of either the USB or LSB signal generated in an earlier stage to a desired output frequency, this stage sometimes does a bit more! The "more" bit is the alteration or change of position and characteristics of the SSB signal – an LSB signal becomes USB, or a USB signal becomes LSB.

Since an inversion occurs in some cases, and in others it doesn't, the question naturally arises as to whether the occurrence or nonoccurrence in a given situation can be predicted reliably. It can.

Let's suppose that we're introducing to the mixer a 9 MHz USB signal and injection frequencies from the output of a 5.0 to 5.5 MHz vfo, from which mixture we obviously obtain output in the 20m band by utilizing the *sum* frequencies, and output in the 80/75-meter band by utilizing the *difference* frequencies. On either of these two bands, our output will be USB, the same as our input sideband signal, as no inversion will result when any sum frequency is utilized, and no inversion will result *in this situation* when any difference frequency is utilized. If, in this example, we used an LSB input signal instead, our output on either band would be LSB for the same reasons.

Before presenting an example of a situation in which an inversion *will* occur, however, it should be pointed out, even though it's pretty apparent that to obtain outputs in bands other than 20 and 80m, we will require injection frequencies additional to those supplied by the vfo alone. Premixed injection frequencies for this purpose can be obtained simply by employing an auxiliary oscillator along with our vfo.

Now, let's suppose we're interested in working, say, the 15m band using the same 9 MHz USB signal. Using a premixed range of injection frequencies from 12.0 to 12.5 MHz, we could obtain outputs from 21.0 to 21.5 MHz by using the sum frequencies, and our output would be USB, the same as our input sideband signal, since no inversion would take place. However, using a premixed range of injection frequencies from 30.0 to 30.5 MHz instead, outputs in the same range (21.0 to 21.5 MHz) could

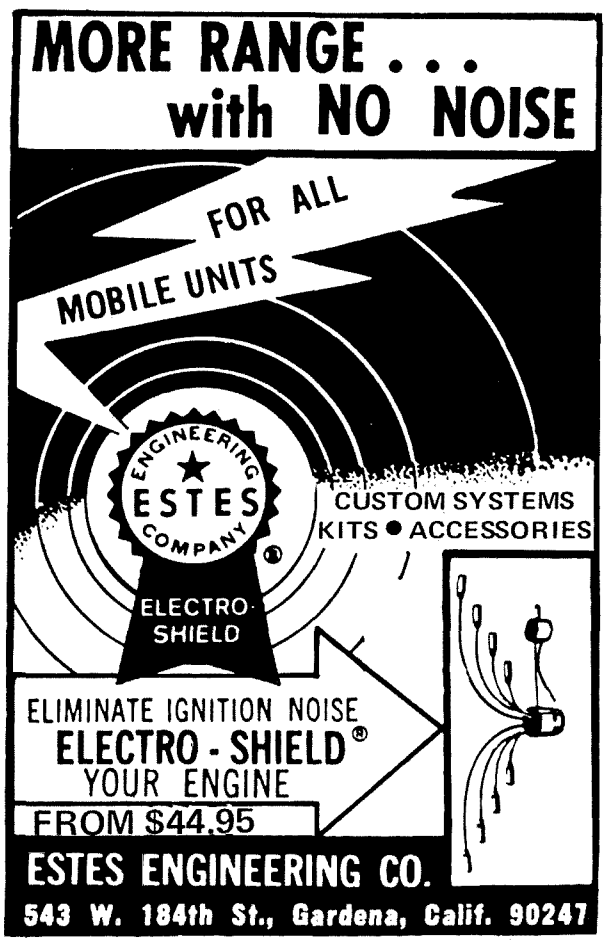
be obtained by using the difference frequencies, but here an inversion *would* take place and our output would be LSB. To obtain a USB output, using the 30.0 to 30.5 MHz injection frequencies, our 9 MHz input signal would have to be LSB.

We've offered two examples here involving utilization of *difference* frequencies, in one of which examples we've claimed that an inversion *will* take place, and in the other we've claimed that it *won't*. Since both examples involved difference frequencies, there must obviously be some difference in their differences. The difference in the difference frequencies, to keep things simple, could be labeled as *positive* and *negative* differences, with the appropriate label being established simply by subtracting the injection frequency from the input sideband signal frequency, but *never* the other way around!

In any case where the injection frequency is *lower* than the input sideband signal frequency (as when, to obtain 80m output, we mixed the output of a 5.0 MHz vfo with a 9 MHz sideband signal), a

Table I. Sideband Inversion Logic

GIVEN	Frequency A (USB) Frequency C (Inj Freq)	Frequency B (LSB) A or B
APPLICATION	Frequency A (USB) minus Freq C Mixer Output 1 (USB)	Frequency B (LSB) minus Freq C Mixer Output 2 (LSB)
GIVEN	Frequency D (Inj Freq)	A or B
APPLICATION	Frequency A (USB) minus Freq D Mixer Output 3 (LSB)	Frequency B (LSB) minus Freq D Mixer Output 4 (USB)



positive difference will result. Subtracting 5.0 from 9.0 gives a *positive* difference of 4.0. Likewise, in any case where the injection frequency is *higher* than the input sideband signal frequency, as was the case when, to obtain 15m output, we mixed frequencies from 30.0 to 30.5 MHz with our 9 MHz sideband signal, a *negative* difference will result. Subtracting 30.0 from 9.0 gives us −21, since we're subtracting larger figures from a smaller one, which differences are clearly *negative* differences.

Proof covering the claims made in this article as to when an inversion will occur and when it won't is available in two forms, either of which should suffice to dispel any doubts concerning the reliability of these claims. One involves the examination of an actual rig utilizing frequencies identical to those used in our examples, and the other involves recourse to "sideband inversion" logic.

The popular combination of a 9 MHz sideband signal and a 5 MHz vfo, which was used in our examples, along with an auxiliary oscillator, when needed, is utilized in the Hallicrafters HT-46 transmitter, which makes it one of a number which could serve to illustrate the occurrence or nonoccurrence of inversions in the manner claimed. On the band selector of the HT-46, we find the 80 and 20m bands marked in *red*, and all other bands marked in *white*. Encountering this situation cold, it would be natural to suppose that something happens on 80 and 20 that doesn't happen on any of the other bands. But, having already read the information offered earlier in this article, you will have guessed correctly that exactly the opposite is the case here. The red markings indicate the bands on which inversions do *not* occur, and the white markings indicate those bands on which they *do*, even though no mention of inversions, as such, is made anywhere in the operating manual on this rig. Output in the 20 and 80m bands is obtained by utilizing *sum* frequencies for 20, and *positive* differences for 80, in both of which situations we claimed that no inversion will result, which claim is supported by both of these bands being marked in red. Output in all of the other bands (40, 15, and 10) is obtained by utilizing *negative* differences, in which situations we claimed inversions will always occur, which claim is supported by the white markings for each band obtained in that manner.

Our alternative proof is in sideband inversion logic, as offered in Table 1. If frequency A represents the upper sideband of any pair of sidebands and frequency B the lower, then, by the definition of sidebands themselves, A must be higher than B. Frequency C in our chart represents any injection frequency lower than A or B, and frequency D represents any injection frequency higher than A or B. The substitution of any actual frequencies for the letters in the table will establish that, without exception, inversions will occur only with *negative* differences.

A MEDIUM FREQUENCY CONVERTER FOR HIGH FREQUENCY RECEIVERS

When today's "oldtimers" were learning the code in the '20s and '30s, they copied a lot of it on the "medium-frequency shipping band." Today's communication receivers seldom cover the broadcast band, let alone frequencies below 530 kHz. There are many interesting signals to be heard on 500 kHz; passenger liners, cargo ships, coastal stations, commercial traffic, ship position reports and weather bulletins. The MCW signals on these frequencies pack a distinctive punch; fellow ex-marine radio operators will know what I mean; and recently I decided to settle an urge to hear them again. Almost every ham I know has one or more old BC radio sets in his junkbox, and this seldom-used junk is just what you will need for this simple medium-frequency converter. Component values are not critical, and the unit gives excellent results.

My station receiver is a Drake 2B and tunes from 3.5 MHz to 4.1 MHz on its lowest frequency band. With this converter, I can tune from 400 kHz to 1000 kHz, using the 2B on 80m. I used a 3100 kHz crystal with a trimmer capacitor across the socket to adjust the crystal frequency to exactly 3100 kHz, and get accurate frequency readout from the 2B dial. Any similar crystal will do if you make suitable allowances; e.g., 3200 kHz will give a tuning range of 300 to 900 kHz. If you have a 3500 kHz crystal and are not interested in the lower part of the broadcast band, you can use that instead. In theory, this will give you a tuning range to 600 kHz. I tried a 3500 kHz crystal, and found that I could hear signals as low as 200 kHz, despite the fact that the converter input will only peak to just below 400 kHz with the component values given. From 200 to 400 kHz you will hear a variety of radio navigation beacons, and from 400 kHz upwards, you will tune the shipping band.

The tuning capacitor is an old two-section variable with both sections in parallel, and a 100 pF mica added to give a total capacity of about 1000 pF. If your junkbox offers you a three-gang type, by all means use it. The coil is a standard broadcast band antenna coil, from a set that used a wire antenna rather than a loop or ferrite rod. If in doubt as to which winding is which on the coil, the commonly used connections are shown on the circuits of Figs. 1 and 2. If you have an unmarked coil, you have an excellent chance of wiring it right first time if you measure the dc resistance of the windings with an ohmmeter; the tuned winding normally has the lower resistance of the two. As well as the coil and capacitor, the old radio that I stripped had a triode hexode converter tube (6K8). Having used

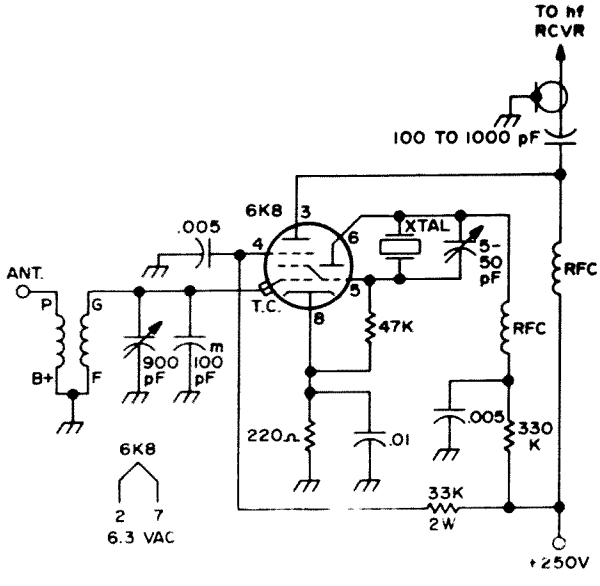

Fig. 1. A medium-frequency converter for high frequency receivers using a 6K8.

the coil and capacitor, I used the tube, too. Pentagrid tubes such as the 6SA7 and 6BE6 are not suitable for this circuit due to their internal construction; however, an excellent modern tube for this converter is the 6U8 triode pentode. Circuits for both tube types are given.

Use as low a voltage as possible on the oscillator section plate, consistent with reliable starting of the crystal. This minimizes spurious mixing and breakthrough of unwanted signals. If your B+ supply differs greatly from my 250V, it may be necessary to alter the values of the B+ line resistors, but they should be near enough for voltages from 220 to 280V. If you use a 6U8, you may have to experiment with the oscillator plate resistor to find just what value is best; I suggest you use a 500 kΩ pot at first, and adjust it to a setting that gives good results; then replace it with a fixed resistor of the same value. The bypass and coupling capacitors in both circuits are not critical in value; in Australia, a very convenient source of .005 μF disk ceramic capacitors is discarded starter units for fluorescent lights. Each starter contains a glass-enclosed switch and a bypass capacitor. The rf chokes can be any that you have on hand; if one is better than the other, use the best one in the mixer plate.

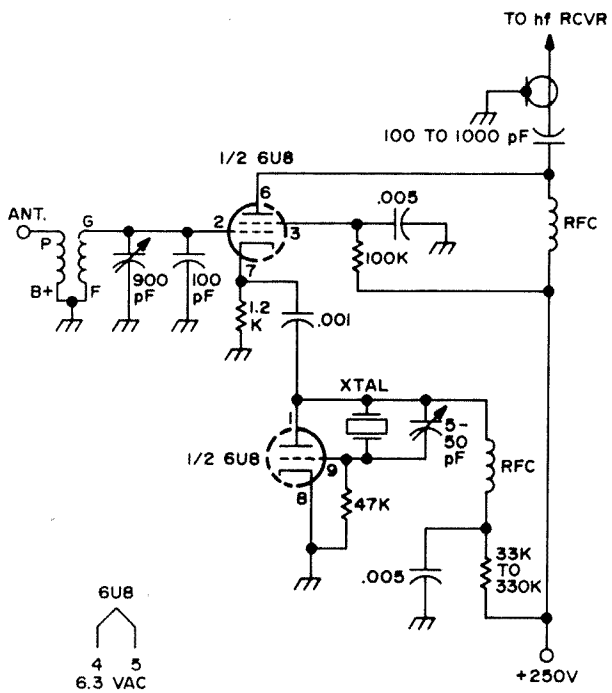

Fig. 2. Converter circuit built with 6U8.

The cable from the converter to the receiver antenna input should be coax of course; anything in the 50–75Ω range is ideal.

The power requirements could probably be met from most receivers, but I take my power from the lightly loaded supply that feeds my vfo. The converter was built on a small chassis of 9 by 3 by 2 in., which suits the space I had available on the radio desk.

In use, I select the required frequency on the Drake dial, peak the preselector tuning, and then peak the required medium-frequency signal with the converter tuning capacitor. My station antenna is only a 67 ft long, Windom-fed, inverted vee, 25 ft high at the center, but seems adequate for 500 kHz reception, as I have heard signals over 2000 miles away at night, and up to 500 miles by day.

The coastal radio stations call on 500 kHz, and use one working frequency, generally between 414 and 492 kHz, though one or two frequencies have been allocated between 514 and 520 kHz; the power is around 2 kW. Ships call on 500 kHz and have 410, 425, 448, 454, 468, 480, and 512 kHz for working frequencies. Most cargo ships run 500–900W, and passenger ships run up to 2 kW. All stations observe two "silent" periods each hour; two 3-minute periods beginning at 15 past and 45 minutes past the hour.

Hams who are boating enthusiasts will find the local coast stations' weather bulletins of interest, and with code speeds varying from 15 wpm to over 25 wpm, there is plenty of practice available. The quality of code varies, too; from the roughest imaginable, to the perfection of machine type Morse.

This converter can be used with any receiver that covers 3.5–4.1 MHz or higher; build it yourself and see how interesting the lower frequencies can be.

My grateful thanks are due Gil Moody (VK3ZR) for suggesting that the mixer plate load be an rf choke. Without this advice, I would certainly have used tuned output, and run into no end of trouble with tracking problems and receiver overload.

EASY END FEED Z-MATCH

If we look for the quickest, easiest, cheapest way to put out a signal on any band from 80 to 10, we see that the answer is an end-fed wire. This has extremely variable characteristics in terms of radiation, depending on length, band, direction, etc. On any particular band it is generally about as good as a dipole, if similar in length to a dipole for that band. On lower frequencies it may be a quarter wavelength or less, while on higher frequencies it would be two half-waves, or more.

The beauty of the end-fed wire is that in practice it can be *any* length. This means it is strung between the two best available supports, with one end (adequately insulated) descending into the shack. It may be vertical, sloping, horizontal, or a mixture of these, and is probably longer than about 20 ft, though it is unlikely to be over about 125–150 ft unless you are lucky with space.

Its feed impedance will be a variable thing, according to frequency, length, and other factors. The usual transmitter or transceiver pi output tank is mostly intended to work into a load of about 50 to 75Ω. So inevitably, this and the end-fed wire will be incompatible on some bands.

Z Match

An impedance or Z-matching device between transmitter and end-fed wire corrects matters so that all but extremely short wires will load the transmitter. Figure 1 is a simple but practical circuit. L is a robust tapped coil, and the variable capacitor is about 150 pF, wide spaced for other than low power. This was found satisfactory for any wire from 10 to 150 ft. With shorter wires arcing occurred. The longer wires naturally radiate better.

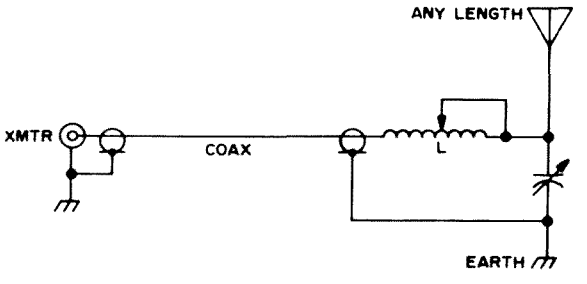

Fig. 1. Circuit of the type used.

ESE ENTERPRISES

506 Main St. • El Segundo, Ca 90245 / 772-6176

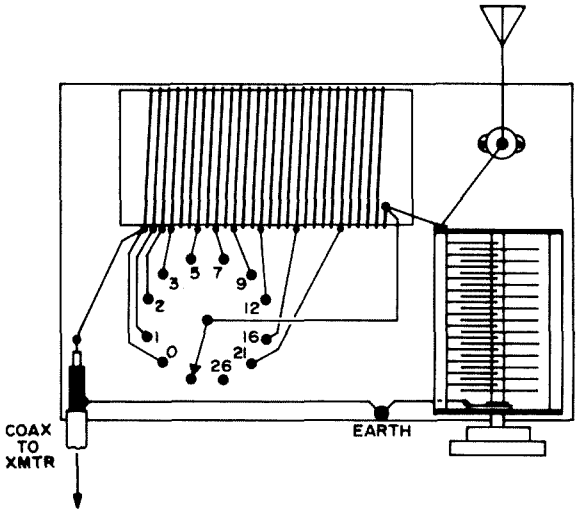

Fig. 2. Coil and other details.

This is a good opportunity to use a surplus inductor. The one actually used was wound for the job, however. It had 26 turns of 16-gage wire on a 2½ in. diameter ceramic form, the winding taking up 3½ in. Stout leads soldered on go to the tabs of a 12-way rotary switch (Fig. 2). The switch selects the following numbers of turns – 0 (coil shorted), 1, 2, 3, 5, 7, 9, 12, 16, 21, and 26 (whole coil).

An swr indicator may be put in the coax from the transmitter to Z match. A good earth ground is helpful. Remember, there may be considerable rf on the antenna connection.

The receiver or transceiver S-meter should give a guide to tuning. Begin with the capacitor at minimum, and no turns in circuit. Rotate the switch to bring up signals. When the best point is passed (too many turns) rotate the switch back one position, and peak the variable capacitor for best reception.

Adjustments are somewhat similar for transmitting. If the TX pi output capacitor is at about a setting which would work into around 50–75Ω, rotating the capacitor with the correct number of turns in circuit will show a point where the system draws power and can load the transmitter.

It was found that with quite long wires, the variable needs little or no adjustment over a fair section of a band. But with short wires, it has to be retuned with other than small changes in frequency.

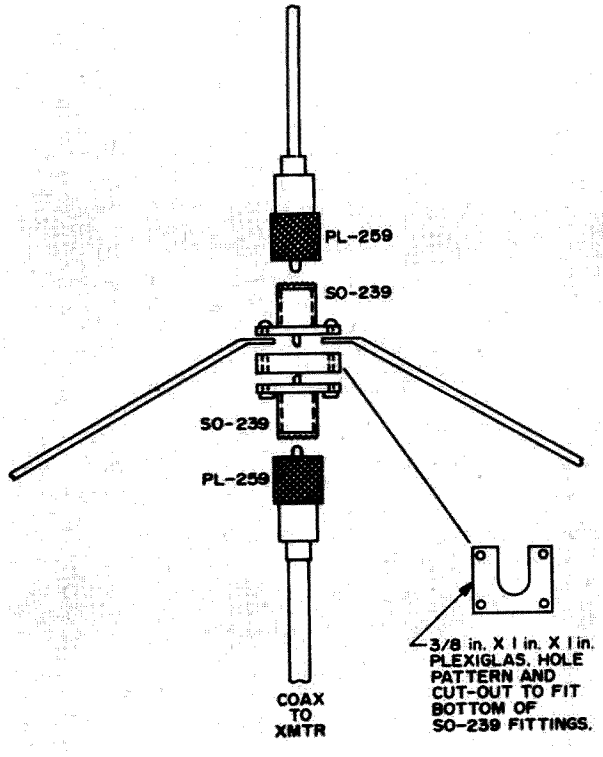
Coat Hangar Antenna for 2 Meters *REVISITED*

When I saw the coat hanger antenna for 2 meters in the June 1969 73, I knew it was just what I was looking for, so I made one. It works nicely, but a few changes can make it even better. Since I use one 10 ft length of coax to connect transmitter to dummy load and transmitter to SWR, I wanted to use the same piece of coax on the antenna, but the original article had it soldered to the antenna directly. I made two modifications on this antenna, and now the coax is removable and it is now impossible to put an eye out with it. The grounding plane section of the antenna is dismantled and put together as follows:

1. Put two connectors, No. SO-239 back to back and solder them together with about ½ in. space between them (see diagram).
2. Cut a piece of plexiglas 3/8 in. thick, the size of the connectors (about 1 x 1), and cut out the area indicated on the drawing, then put it back together. Now you can screw the cable on and off when packing the antenna or storing it.

If you are afraid someone might get poked in the eye with the grounding section of the antenna, put four foam balls on the ends of the elements and paint them a bright color. I painted mine a bright orange and it really stands out. If you like your homebrew equipment to have your call letters, paint them in black on the colored balls. It really stands out. Good luck.

. . .Gelsinger■



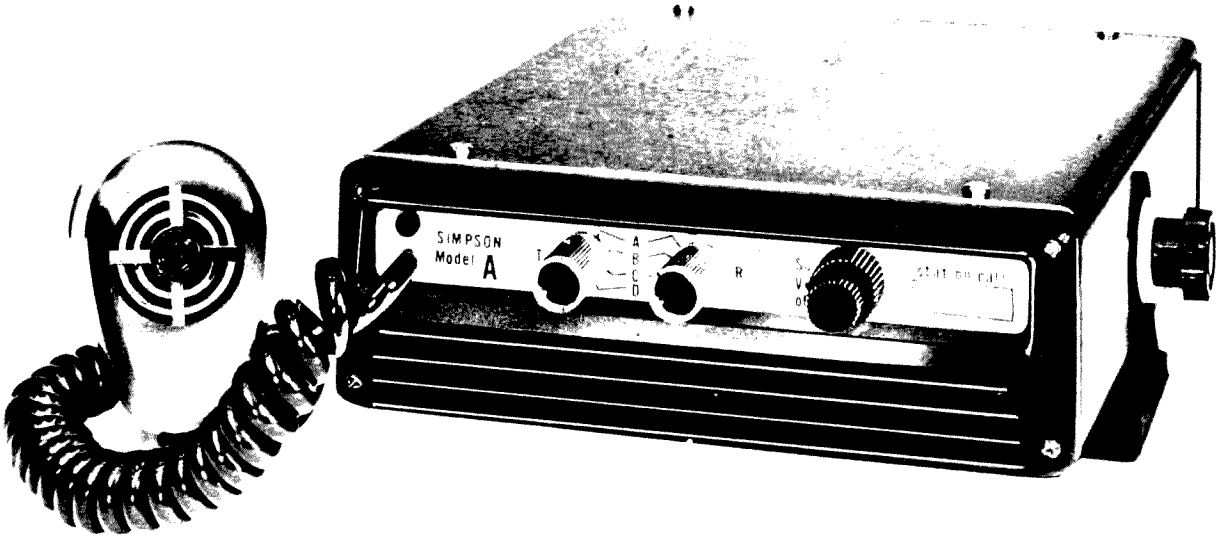


Fig. 1. Construction details of the improved groundplane.

73 Uses the Simpson Model A FM Transceiver

This is an amateur model of the very well known Simpson Model T marine transceiver, a four channel 150 MHz FM transceiver. The amateur who is looking for an American built unit of exceptional quality would do well to take a close look at the Model A.

Some of the features which make this transceiver so interesting to the FMer are its uncompromising construction, with nothing left out for economy. There are four transmit channels and four receive channels, and any may be paired with any other if you live in a mixed-up repeater area with machines on, say, 22-76, 22-82, 16-76, 25-76, 25-88, 28-88, 31-88, etc. Independent switching of the receive and transmit channels just may

be the way things are heading.

By tilting the oval loudspeaker back and building in a small air coupling section in front of the speaker, the Model A is capable of putting out a remarkably good sound. If your car has much more noise than a Rolls you may just need all the loudspeaker you can get to hear what is coming out of your receiver and you may find the usual 2 in. speaker a whisper in a windstorm when you rev up through the gears.

Separate boards are used for the receiver and transmitter functions, a fact which has alerted some of the more devious technicians in our midst to the possibilities of using the Model A for a repeater. All it takes are a few

wiring changes and a carrier operated relay to make the basic change. To my knowledge there are well over a dozen active repeaters around the country today using the Model A boards.

The transmitter puts out a minimum of 6 watts and uses the popular 6 MHz crystals (the same as the Regency transceivers). That power level is quite adequate for most repeater operation and represents a good compromise for your car battery longevity. You can always put in an external booster amplifier for boondocks work.

The receiver has a ceramic filter with 6 dB skirts at 13 kHz and 60 dB at 36 kHz, which means that a strong signal on 91 will not wipe out both 88 and 94 for you as it will in some other popular receivers. One good strong 91 machine can raise Ned for a hundred miles on three channels unless everyone has good selecting receivers. Sure, you can always buy a $15 filter and put it in yourself, but that means drilling holes and work which could be avoided if you chose a receiver with narrower bandwidth.

The oscillators all use diodes for switching, which means that you can actually switch channels from any distance you wish. This system is ideal for use with remote base installations where you might have the transceiver up on the top of a mountain and remotely operated by 450 MHz link or phone wires. You may not be able to live on top of a mountain or a tall building, but you might be able to stick a remote rig up there, which is the next best thing.

The oscillators are padded enough so you can buy inexpensive low tolerance crystals and zero them in. The pads are right out there where you can tune them too, rather than requiring a deformed midget with a lot of patience to get your crystals on channel.

The Model A is in a flat pack that will fit under the dash of most cars and still leave plenty of leg room. The box is made of extruded aluminum side rails with vinyl covered aluminum top and bottom covers and a front panel of injection-molded Cycolac. The circuit boards are glass expoxy and the parts are machine-wave soldered to them. In all, it is an extremely professional and commercial quality job of construction.

It also works.

The CT POWER Amplifiers

Knock that repeater right off the mountain!

One of the neatest, most professional wiring jobs we've ever seen!

This new concern in Hawthorne, California, is producing a line of eight two meter power amplifiers which are being marketed by Henry Radio as part of their Tempo line. The 45 and 60 watt output amplifiers are available for driving powers of one, five or ten watts, while the 100 watt output models can be driven with five or ten watts.

While the ten watt output of most of the FM transceivers is quite adequate in the primary coverage area of repeaters, what amateur has not fretted when he was far enough out to copy the repeater solid, but could not trigger it? A hundred watt amplifier will give you quite a few more miles of good solid repeater usage, you may be sure.

But fellows, be fair, put in a switch to cut out the amplifier when you are close enough in so it isn't needed. No one is going to love you if your signal comes crashing in on top of all the other mobiles. Use these power amplifiers as a force for good, not as a means for getting on every shoot list within repeater range.

JEFF-TRONICS

4252 Pearl Rd., Cleveland, OH 44109

One hundred watts from your mobile rig will stomp everything in town, including most of the home rigs. At 13 amperes it will deflate your battery unless your car is set up for this type of demand. An alternator system has a lot to recommend it when you are asking this from the car. Perhaps the 45 watt unit is more practical for your system with its 5A demand. 45 watts is still a lot of soup and should easily double your range into the repeaters.

Are these amplifiers difficult to install? No. Being small, 3" x 4" x 8½" for the 100 watt model, they will mount just about anywhere. My own preference is on the firewall under the front hood where the battery cable can be relatively short and deliver the 13.8 volts in good shape to the unit. A coax cable from the amplifier runs through the wall to the back of the transceiver, while the antenna connects to the other end of the amplifier.

When you turn on your transmitter a bit of the rf is rectified as it enters the amplifier and this actuates a send-receive relay, switching the antenna to the output of the amplifier. A 2N2222 transistor is used for the switching function, and TRW PT-8710s are used for the amplifier, with one as a driver and three in parallel in the final. As soon as the ten watts of rf stops coming through the hose from the transceiver the relay reconnects the antenna to the transceiver, cutting the amplifier out of the circuit.

If you are having trouble getting into a repeater you might consider going the power amplifier route.

In Action!

Using the Tempo 100 watt amplifier I have yet to find one repeater that I can hear well that I can't get into. With the amplifier off, my signals are frequently either marginal or else just don't make it at all when I get on the other side of a mountain, even though I can hear the repeater enough to copy it.

If you can get into every repeater you can hear, then you have nothing to gain from adding an amplifier. If your signals fade out before the repeater, perhaps this is your answer as it was mine.

OPTIMAL VERTICAL ANTENNA LOADING TECHNIQUES

The author discusses the various techniques used to load vertical antennas. From the viewpoint of reasonable performance, ease of construction and bandswitching, a combination of top and base loading is favored. The construction of a pratical antenna is illustrated.

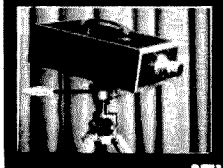
Many amateurs are faced with antenna placement situations which do not allow the erection of full-sized antennas. A loaded type of vertical antenna is often the only antenna possibility. Often, even a trap-type vertical cannot be used on the lower frequency bands because of the size of such an antenna and its support requirements. The only choice then is to use as long a vertical antenna as possible with as much loading inductance as necessary to resonate the antenna on a desired band. The physical length of such an antenna may be 1/6 or less of the electrical length it represents through inductive loading.

The subject of how to produce efficient, extremely short-loaded antennas has been the subject of numerous studies by commercial and military organizations. The purpose of this discussion is not to delve into the more advanced techniques which have been developed since such techniques often require special construction and special equipment for a relatively small gain in antenna efficiency. This approach may be necessary in some situations where the capacity of the power supply for a portable transmitter is limited and the only possibility to improve the radiated signal is through increased antenna efficiency. In the amateur case, and particularly for the newcomer who starts with a low-power transmitter, it is often easier and more economical to first try increasing the transmitter output level (via an inexpensive linear amplifier, for instance) rather than getting involved with complicated antenna construction projects. Therefore we will discuss only the simple forms of antenna loading which have been well proved and which are easy to build. The material is particularly oriented toward the newcomer who would like to construct a simple loaded type of vertical antenna that will give reasonable results on one or more high-frequency bands.

Loading Variations

A full-length quarter-wave antenna will have the current distribution shown in Fig. 1A. If the physical length of the antenna is made shorter than the required electrical length, a loading inductor can be used to establish the correct electrical length. When this is done, the current distribution may appear different than in Fig. 1A, depending upon where the loading inductor is placed. If the loading inductor could be distributed over the entire length available for the antenna (helical loading) the current distribution would look the same (Fig. 1B). Placing the loading inductor either at the extreme top or bottom of the antenna will

POWER SUPPLIES



Excellent for 12 volt transceivers, general purpose experimenting, or for I.C. logic. Each supply features I.C. voltage regulation. Output voltage varies less than 1% of supply voltage from no load to full load. The power supplies are also current protected. A momentary short will not harm this unit.

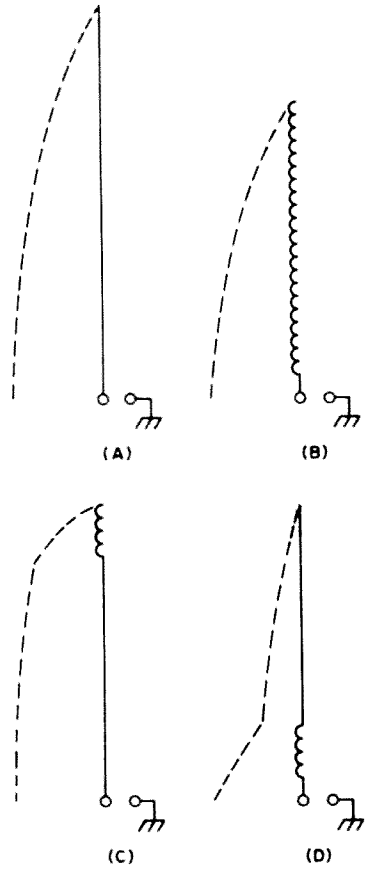

Fig. 1. The dotted lines show the current distribution on a full length ¼λ vertical antenna (A) and various forms of physically shorter, inductively loaded antennas.

produce the current distributions shown in Figs. 1C and 1D. Various points can be advanced for either top or bottom loading. Top loading has the advantage that the greatest current flow will take place in the metal rod section of the antenna and, therefore, less I^2R losses will take place in the loading inductor on top. Bottom loading has the advantage that the loading inductor can easily be bandswitched. Also, if the loading inductor is constructed of heavy enough wire, the losses can be held to a tolerable level.

Aside from placing the loading inductance either at the extreme top or bottom of the antenna, one could also place the loading inductance at the center of the antenna or place a portion of the inductance at the top and a portion at the bottom of the antenna. The current generation of mobile antennas generally uses center loading because of a

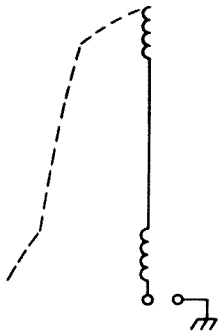

Fig. 2. Splitting the inductive loading to both ends of the antenna produces the current distribution shown.

combination of electrical and mechanical factors. The loading inductor need not be as heavy as a base-loading inductor to keep losses to a reasonable level, and the physical placement of the inductor allows a flexible upper section for the antenna, as well as access to the inductor for bandswitching by changing inductors. However, for home-station usage, the proper placement of part of the loading inductance at the top and bottom of the antenna, as shown in Fig. 2, has a better combination of electrical and mechanical advantages. The placement of part of the loading inductance at the base does not optimize the situation where the highest current flow is through the metal rod of the antenna, but it is also true in a practical situation that the most severe ground losses would still take place at the base of the antenna. So the actual increased loss that results as compared to solely top loading the antenna is a small price to pay for the convenience factors involved in bandswitching and impedance matching the antenna to a transmission line. The top loading that is used insures that a good portion of the highest current flow will take place in the metal rod.

Finally, the splitting of the loading inductance between the base and the top of the antenna greatly simplifies construction of the antenna for home station usage where a single long aluminum or steel piece of tubing is used as the main element of the antenna.

Sub-Audible tone Decoder $9.95

Encoder $8.95

- Compatible with all sub-audible tone systems such as Private Line, Channel Guard, Quiet Channel, etc.
- Glass epoxy PCB's & silicon xstrs throughout.
- Any reeds, except special dual coil types may be used: Motorola, G.E., RCA, S.D.L., Bramco, etc.
- All are powered by 12 vdc.
- Use on any tone frequency 67 Hz to 250 Hz
- Small size 1.5 x 4 x .75"
- All parts included except reed and reed socket
- Postpaid – Calif. residents add 5% sales tax

TV - 7/U ELECTRON TUBE TESTER
PORTABLE DYNAMIC MUTUAL CONDUCTANCE TYPE

Used to test and measure the performance capabilities, and to determine the rejection limits for Electron Tubes used in Receivers, low power Transmitters, & in many other electronic equipment. The tests made are for dynamic mutual conductance, emission, shorts, gas, noise, continuity, pilot lamp, etc. Test sockets are for loctal, octal, 4, 5, 6, 7 pin, Norval 9, 7 pin miniature, sub-min. rd. & flat, acorn, etc. With special adapters (THAT ARE OPTIONAL) 829, 832, 2C39 and sub min. tubes with long leads also can be tested. Power required: 115 Volt 50 to 1000 cycles. Tube test data charts, test leads and pin straighteners for 7 & 9 pin are included. Size: 6 1/4 x 8 1/2 x 15 3/4". Wt.: 20 lbs. PRICES: Used, serviceable - $19.95 Checked - $25.00 Adapter for 2C39 - $5.00 For 829/832 - $5.00 For sub-min. Lg. Lead - $3.00 All prices FOB Lima, OH.

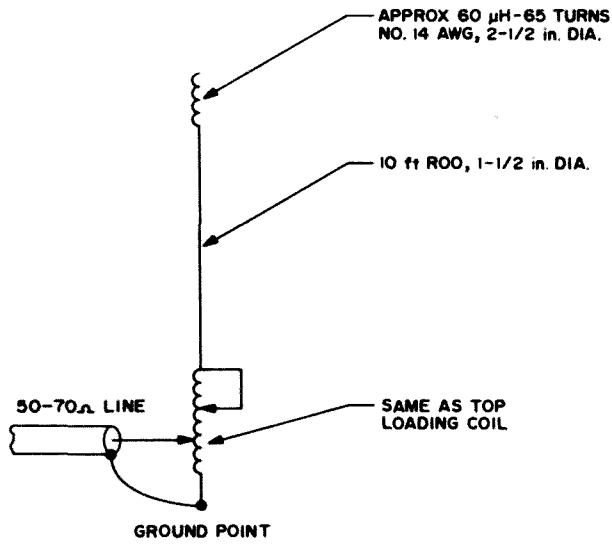

Fig. 3. Dimensions and coil sizes for 80/40m antenna.

Practical Example

Figure 3 shows a simple antenna using a 10 ft aluminum rod and top and base loading which I constructed for use on 80 and 40m. The maximum amount of top loading was utilized that would still permit enough base loading to be present on 40m so a coaxial transmission line could be tapped on the base-loading inductance for a proper impedance match. For the 10 ft rod, this meant a maximum top-loading inductance of about 60 μH. Since the top loading is fixed, this meant that the base-loading inductance has to be increased as necessary on 80m to resonate the antenna. Again, about 60 μH is necessary. The coil dimensions shown in Fig. 2 are those for which B&W or Air Dux coil stock is available. If possible, it would be desirable to increase the diameter-to-length ratio of one or both coils (maintaining the same inductance) so that the diameter is about half the coil length. This would raise the Q and improve the overall antenna efficiency. Such construction would make it more difficult to tap the transmission line on the base-loading coil but it should be easy to implement for the top-loading coil. The top-loading coil used is a salvaged coil from

a commercial trap-type vertical antenna. The necessary loading inductances for other bands or with other lengths of tubing can either be calculated from handbook data or it can be easily experimentally determined. In the latter case, the maximum amount of top-loading inductance is used on the highest frequency band that still allows a sufficient amount of base-loading to permit matching the transmission line. The base loading is then increased as necessary to resonate the antenna on the lower frequency band.

An swr meter is the only instrument necessary to adjust the antenna. Starting on the highest frequency band, the minimum amount of inductance is used in the base coil that permits the transmission line to be tapped on with a 1:1 swr. On the lower frequency band, the base coil tap is first changed to bring the swr down and then the transmission line tap readjusted to finally lower the swr. It may be possible to find a compromise tap point for the transmission so its position does not have to be changed when changing bands. The actual changing of the coil or transmission line taps can be done with relays or manually with clips, as desired.

Summary

No simple, short-loaded antenna will be extremely efficient on the lower frequency bands. However, the antenna described will work reasonably well for its size and it is a practical solution for a simple to construct and inexpensive antenna where space is limited. One point that should be carefully observed in installing the antenna is to provide a good ground connection either in the form of radials or connection to some large metal structure. If no ground connection possibility exists where it is desired to install the antenna and no room exists for radials, two antennas with similar loading coil arrangements can be combined to form a vertical dipole, or they can even be mounted at right angles to each other in the form of an L.

Amateur Radio

FEBRUARY MCMLXXII Monthly Ha

MILESTONE WIN IN TOWER CASE

A classic victory for tower-owning has occurred in California recently. Some neighbors of such a man filed a lawsuit and got an injunction against the ham. The defending lawyer, also a ham, managed to win the case in favor of his client; in other words, the ham won. Rather than sit back and congratulate himself, the lawyer examined the injunction against his client.

In California, and possibly other states, such an injunction must be backed by a bond. The lawyer filed a claim against the bond for court fees, attorney's fees, and reasonable reparations (damages). The bonding company, it was found, had filed the bond to the wrong person and after much litigation, somehow managed to clear themselves and shifted the liability to the home owners who had filed the lawsuit and got the injunction.

The lawyer feels sure he will be able to collect fees and perhaps some reparations. The whole point is that a countersuit has been filed against the neighbors and the ham is in the driver's seat. Congratulations to the ham and his lawyer who did not give in under pressure and who have created a precedent in amateur radio.

IN OKINAWA...

BLIND HAM HONORED FOR PHONE PATCH SERVICES

Betty Blalock KR6BB, Awards and QSL Manager for the Okinawa ARC, presents the Okinawa DX Award for Ken Hinderleiter K7HQF, for service to the residents of the island. From left to right are Gordon Hale KR6RH, President of the Club, Ken, Mrs. Hinderleiter, and Betty Blalock KR6BB.

Ken Hinderleiter K7HQF, a blind ham from Phoenix AZ, has provided phone patches to the U. S. from Okinawa for over eleven years. Handling, on the average over 1,000 calls per month, Ken has performed a much appreciated service for American military personnel and their dependents. In appreciation of his service, the Assistant Secretary of Defense/Public Affairs invited Ken and his wife to Okinawa to attend the semi-monthly meeting of the Okinawa ARC to meet many of the people he has spoken to over the years. He was presented with an honorary membership to the OARC and he received the call letters KR6HT. At the meeting, Ken also was presented the Okinawa DX Award for the services he has unselfishly given, often placing calls in the small hours of the Arizona morning.

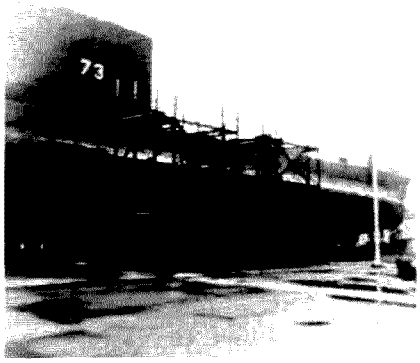
75th Anniversary of the Birth of Radio Communications



From May 14–21, 1972 the Barry College of Further Education Radio Society will be commemorating the 75th anniversary of the Bristol Channel Tests undertaken by Marconi and Kemp in May 1897. They will be establishing stations at Flatolm Island (GB3BCT) and Lavernock Point (GB3MKT).

The 1897 tests were significant in that radio signals were transmitted for the first time across water, radio signals were transmitted for the first time between two countries, and these were the last tests carried out by Marconi as an amateur. The 7th anniversary of such an event should not pass without special recognition.

The Society invites clubs located in areas which have an historical link with Marconi's early experiments to join in establishing special commemorative stations sometime between May 1972 and May 1973. The Society will award a special 75th Anniversary Certificate to radio amateurs who contact these stations. In the U.S. the Old Old Timers Club will handle the Marconi-Kemp celebration exclusively. Thei Vice President, William B. Gould K2NP, has been designated as the individual in charge of the project.

To emphasize the international aspect of amateur radio, overseas amateurs holidaying in Britain are invited to visit the historic site at Lavernoc Point, and operate across the stretc of water made famous by Marconi. special commemorative certificate will be issued to all amateurs operating this historic link. Any reader interested in visiting the site should writ in the first instance to K2NP, and Bill will be able to supply him with th necessary information for obtaining a reciprocal license. A special first-da cover stamp will be issued from Flatholm Island. Information on th stamp may be obtained (with I.R.C.) from GW3VBP.

International Net

MARCO SAVES LIVES

Jerome Hurwitz W3EZT, was in his Silver Spring shack on November 12 when he heard a distress call from Venezuela. The South American was in dire need of a special medicine for a two-month-old boy in Caracas. Jerome, an engineer by profession, served as a relay between the State and Defense Departments, Panama, and Caracas. Within 24 hours, the medicine was safely on its way to Venezuela from New York.

Although this is not the usual substance of ham radio, emergencies such as this do occur and it is only because of the operating skill of dedicated hams that tragedy is avoided. There is a special net that meets on the air just for the purpose of exchanging information of a medical nature. This is the Medical Amateur Radio Council, MARCO for short. This is an international effort to share medical knowledge and to lend assistance where possible. MARCO frequencies are: 7264 kHz daily at 0200Z; same frequency on Monday, Wednesday and Friday at 0320Z; 7060, Monday and Friday, 0230Z; 14060, Saturday and Sunday, 1800Z; 14280, daily, 0300Z; 14280, Sunday for DX SSB, 1900 and 2000Z.

NEWS BRIEFS FROM AROUND THE WORLD

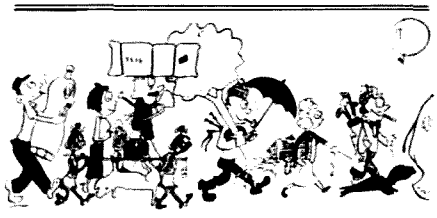
CANADA *(Tnx to Canadian A. R. Federation)*

The Gifford Marsh Memorial Trophy has been presented to Noel Eaton for his selection as Ontario Amateur of the Year. The trophy is presented annually by the Radio Society of Ontario to the Ontario amateur who has given the greatest service to amateur radio on the local, provincial, national, or international level.

The official banned countries list for Canada is: Cambodia (Khmer Republic), Cyprus (except on national and international field days), Gabon, Iraq, Libya, Pakistan, Turkey, Vietnam, and Yemen.

Repeaters in Canada will be under official scrutiny by the DOC, but the exact date for policy notices and even what the proposals will be is not yet final. Any repeater licensee who wishes to keep informed about operation and who wishes to play a role in the formulating of regulations should contact A. M. Vardenbelt VE3FXC, 699 Trojan Ave., Ottawa 7, Ontario. He is the chairman of the CARF auto-repeater committee which is primarily involved in advising on changes necessary in regulations governing the licensing and operation of the machines.

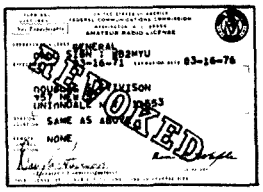
Will there be Novices in Canada? This is a question that many a Canadian may ask himself before the CARF submits its proposal for a restricted class of license to the DOC. This license would allow activity in the VHF/UHF part of the spectrum, and the intent is to increase amateur activity there. What with more general radio service users looking for additonal frequency space, the amateur bands are good places to question if there is no activity there (U.S. hams, remember 11 meters?). Hopefully, the status of amateur will spur the newcomer to obtain full status. Several clubs have commented that they would conduct code classes on the air to help these hams up-grade. Another item that is related to licensing is the proposed lowering of the age requirement from fifteen to twelve years of age. To express your feelings on either or both of these matters, contact your provincial society before a proposal is submitted to the DOC. The proposal that will be offered will be based on the results of questionnaires that the Federation has requested of the provincial groups.



JAPAN *(MARCO News)*

The Hokkaido branch of the JARL has set up JA8IOC in Sapporo in conjunction with the Eleventh Winter Olympics. The objective is to inform listeners about the Olympics and to promote good will with other countries. Until February 13 they will operate CW and SSB on all bands 160 through 10 and six and two FM.

In early 1971, there were 139,400 hams, and almost one-third are in the Kanto area which includes Tokyo.



NIGERIA *(Courtesy NARS)*

There have been few new licenses granted to Nigerians due to the continuing political unrest that began in 1967. Negotiations have been attempted with the Post and Telegraph agency, the governing body of amateur radio in Nigeria, but very little has come of it. Advice that seems to be given to those who would attempt to re-open channels is to not make waves. Some groups have suggested showing films of ham radio activity over local television networks; however, the editor of NARS News recommends the opposite because "One of the aspects of this film is to recruit interested persons to apply for permission to operate a station, and if P & T were suddenly inundated with requests for licenses the reaction from P & T might be rather disastrous."

Moving? Please let us know.

WITH THE FCC

The Federal Communications Commission has passed an amendment to its rules to allow hams to increase speeds on teletype equipment to 60, 67, 75, and 100 words per minute. Previously, amateurs were limited to sixty words per minute, this limit mainly imposed by the type of equipment available. Now, however, more surplus TT gear is being released from commercial service and the ability to increase speed which has previously been denied is being allowed. Arguments in favor of the proposal included increased message handling capability and more efficient use of air time.

The FCC has recognized comments that this move is an advantage, as it promotes experimentation and will permit the development of new skills and techniques, in keeping with the basis and purpose of the Amateur Radio Service. Commission experience indicates that amateur operators have consistently demonstrated their versatility in adapting to new operating situations and conditions. The ARRL was one of the proponents of the measure, commenting that not restricting amateurs to specific speeds and codes would enhance experimentation and contribute to the development of new and improved techniques, experiment and practices.

No limitations to bandwidths were set as other parts of the Rules give indications of good engineering and amateur practices. According to the FCC release with this information, "This is in keeping with the intent of amateur rules to provide technical requirements which permit as much latitude as is practicable consistent with the prevention of undue interference between amateur stations and the prevention of interference to other radio services."

The FCC is there, so be careful to obey the rules. Richard Dixon WA8CKY, was cited for failure to have a licensed ham sign off his station, failure to identify at least once every ten minutes, and failure to file a notice of intended portable operation. Since Richard did not reply to letters to Show Cause why his license should not be revoked, his license was suspended for the duration of its term.

In other recent action, the FCC has revoked the Novice class license of Peter Kuehn WN6IER, Walnut CA. This is the result of improper use of his Citizens Band station, using excessive power, and off-frequency operation. His license is suspended for the remainder of its term, unless Kuehn wishes to appeal the suspension order.

An awareness of the rules is helpful. When someone receives a letter to Show Cause, it is not a suspension notice. It is the person's opportunity to tell what happened in his own words. No response is regarded as an admission of guilt and appropriate action is taken. A suspension order is then issued. If the accused wishes to challenege the order, he may make application for a hearing at which time the suspension notice is held in abeyance until the conclusion of the proceedings.

According to the *DXers Magazine*, we find the following items of interest: AC5TY can be found nightly on the SEA net at 1200Z and goes down to 14305 kHz with 4S7AB. QSL goes to T. Yonten, Thimphu, Bhutan via Calcutta, India. You can list the Republic of Nauru under its prefix of C21, C20 and C29. Portuguese Timor can be found on fifteen and the call is CR8AG. Adriano only recently arrived there but will have his quad up soon. If you work the Pacific Net, look for TJ1AW (QSL via K4MPE). For non-DXers, this is the Cameroons. And for lower frequency DXers, Christmas Island, VK9XX will soon be on 40 and 80 meters. Higher frequency DXers can find him around 14,285 at about 0930Z. In either event, QSL via Stu, W2GHK.

Is UA7KAE/7 really in the South Shetland Islands? That's what his QSLs say.

Fred, VP8KV, Falkland Islands might be found on 14230 SSB around 1015Z and he can be reached at Box 144, Port Stanley, Falkland Islands. The W6's have been working VR1AB, British Phoenix Island between 0500–0600Z around 14285. If you need Brunei and have not yet worked VS5CB, you will be upset to learn that he will soon be QRT. You will be pleased to learn that VS5PW will be on the air soon with a kw. ZK1CD, a real gentleman, will QSY to help others earn the 5BDXCC. He is on the island of Rarorongа in the Cook Island group. Another one to watch for is 3B8CZ, Mauritius. Den can be found around 21300 and also on ten meters. QSL via RSGB. P.O. Box 467, Port Louis, will reach him direct. Togo, 5V7GE(?) skeds K4SKI daily on 14250 at 2100Z, give or take a little.

Only active XU is XU1AA, and he operates only from 0000–1500Z. The FCC is permitting American hams to work ONLY this XU station. QSL to XU1AA, University of Phnom Penh, Box 484, Cambodia.

Some other QSL info: VQ9R, Carl, Box 193, Port Victoria, Mahe, Seychelles.

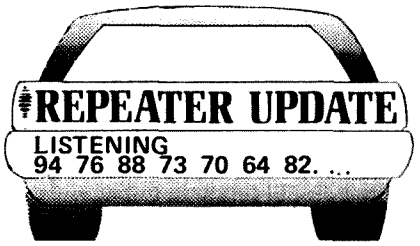
VK Ham Tours Italy & U.S.

Ian Williams, VK3MO, has made many DX contacts from his Melbourne QTH, and so begins a happy tale.

Ian left Australia about the first of 1971 and soon arrived in Italy. There

he purchased a bicycle and toured the continent, stopping off wherever possible to visit the many stations he had contacted before. Of course he did not meet hams everywhere and frequently camped out in fields or construction sites. Twelve thousand miles later the bicycle broke down completely. Ian then decided to visit the U.S. Traveling here was a little easier as he obtained a special bus ticket that allowed him to travel anywhere at any time within a certain time limit *(This ticket is available only to foreign visitors –Ed.)*

In the U.S. Ian had eyeball QSOs with the Americans and operated their stations when possible. In fact, Ian had developed a following of interested and well-wishing hams on both sides of the ocean and kept them all informed as to his welfare. By now he is back in Australia, working more DX stations and perhaps getting ready to ship out again.



Year round DX may soon be a possibility, even during sun spot cycle low points. The National Oceanic and Atmospheric Administration has been conducting research on heating the F-layer of the ionosphere, and possible results might be ways of altering this layer to produce long range radio communication. These experiments extend the ability of man to alter his environment from a distance with no harmful after-effects. So far, the heating effect has been controlled with results lasting seconds, minutes, and sometimes hours.

Results of these studies will prove useful for space as well as intraterrestial communication.

Eric 5N2ABG, reminds us that there is a small independent territory between Norway and Sweden called Morokulien. It is an international refugee area and the prefixes LG and SK9 have been specially issued. LG5GL and SK9WL are active from the territory, and QSLs may be sent to P.O. Box No. 1, N2242/S 67 044, Morokulien, Scandinavia.

Egypt, SU1IM, has been heard around 14057 at about 1500Z, and this is on an almost daily program. Also on 20 CW is VR5FX, Tonga. Usually showing between 0500 and 1730Z, he can be found around 14040, up or down about 5 kHz (QSL via ZL2AFZ). And still another 20 meter man is Keith VKØKA, MacQuarrie. Keith is found regularly on SSB, probably around 1700Z with a good sig to the west coast. QSLs for VKØKA are handled by the VK3 Bureau.

And if you need Africa, listen in to the West Africa Net daily at 21300 kHz.

Interesting note: Varitronics transmit crystals can be used in the Regency HR2. With this change, the 73 Varitronics crystal becomes Regency 76, the 91 Varitronics becomes 94 Regency . . .

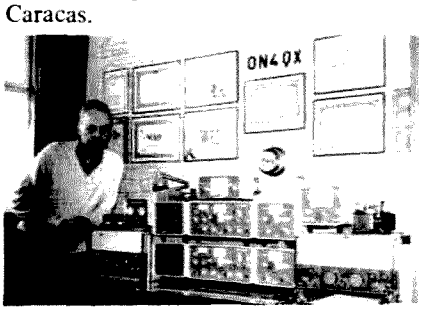
MARS repeaters are being built now and the standard frequencies for them are 148.01 in, 143.99 out. Two such machines are in Ridgefield CT and Beverly MA, and there are plans to have a series of similar repeaters on a Maine to Virginia network.

NEW PRODUCTS

WA6JOX has returned a Consumer Test report about the Vanguard Model 201 rf preamp. His evaluation says this is the "most accurate advertising spec ever seen. Very good product." And as for servicing problems, "None, easy to use." Dick recommends this two meter preamp very highly.

FREQUENCY MODULATOR FOR THE GONSET COMMUNICATOR

The Communicator has been the most popular two meter transmitter-receiver of all time. But it is an AM rig and two meters is now almost exclusively FM. Palomar Engineers' new Frequency Modulator puts the Communicator on FM without any modification or rewiring. The microphone plugs into the Frequency Modulator. One of the cables coming out of the Modulator plugs into the Communicator's microphone jack and carries the push-to-talk line. A second cable has the crystal plug which plugs into any one of the Communicator crystal sockets and the crystal plugs into it. A variable capacitance diode in the crystal plug frequency modulates the crystal and the frequency multipliers in the Communicator increase the deviation to about 8.5 kHz at the output frequency.



(continued on page 8)

The Japan DX Association (P.O. Box 7, Aobadai, Yokohama, Kanagawa, 227, Japan) is negotiating operation from such tantalizing locations as Burma, Bhutan and Iraq. The effort is being aimed at the Japanese Embassies in these locations. Different companies are being contacted as to equipment and travel considerations, too. And there are other possibilities of bringing on some of the rarer DX. Hopefully this will come about, giving many a DXer some new ones to chase after.

In an effort to promote meaningful communications among hams, the Electronic Representatives Association Ham Club has sponsored a contest among their own members and hams in Venezuela. "Eyeball to Eyeball," the project theme, expressed the desire of many hams to meet face to face with the voice on the other end.

Mr. Dave Hollis, the Club chairman, said "Venezuelan and U.S. amateurs who have contributed the most to promote this theme will be presented with a special prize for their accomplishments. Awards are being donated by prominent electronic equipment manufacturers."

The receipt of a QSL card from the American ham permits the Venezuelan operator to attend as a guest the banquet at Interface 2, the ER's 13th annual marketing conference, held at the Macuto-Sheraton Hotel in Venezuela. In order to continue face to face contact after the conference, the ERA Ham Club has received permission from the Venezuelan government to operate ham stations from Caracas.

DX station ON4QX (Bob) since 1936. He is an A2 op. DX 320/300, 294 CW, WPX 848, and a regular reader of 73. He has 250 awards and DX licenses 3A2CZ, ex-IL1QX, LX3QX, 9A1QX, PAØQX. Bob is an ex-radio officer of the British Navy.

EDITORIAL BY WAYNE GREEN

Columnists Wanted

For some ten years now we have avoided running much in the way of monthly columns in 73 . . . but now, with the concept of the newspages, perhaps the time is ripening. What I have in mind is a far cry from the four and five pages of rambling gossip that columns in some other magazines have been running. I'd like to see a short report on activities and news each month as a one-column feature in our newspages. If news is short, the column should be short.

Have we any volunteers to handle monthly reports for our newspages? I'm interested in people who are already expert on their subject, who already have most of their sources of information developed. I would entertain the idea of columns on RTTY, ATV, SSTV, DX, 160m, 6m, FM, 220 MHz, 432 MHz, moonbounce, certificates, contests, ARRL, ICs, Novices, YLs, traffic nets, or what else do you suggest?

I have in mind a column that would run maybe two double-spaced typewritten pages a month . . . plus perhaps one picture. Short and sweet.

Payment? Fame! Also little extras such as your own personalized QSL cards, letterhead paper, a Life subscription to 73, copies of new books as we publish them, and a small cash payment to cover your postage and expenses like that. Fame, mostly.

If you would like to manage a column sit down now and write up a sample of what you have in mind and send it in. Remember that once you start you are responsible to a lot of people to meet that monthly deadline . . . the 10th of the month.

Repeater Pictures Wanted

The 1972 edition of the Repeater Atlas is about to go on the press and we would like to include as many pictures of repeater sites as we can. Have you a good interesting picture of your repeater?

220 News

React has announced that it now supports the EIA proposal for setting up the citizens radio service in the amateur 220–225 MHz band. The full EIA proposal was printed in tiny type in the March 1971 issue of 73, page 124ff. React has petitioned the FCC to act quickly on the EIA proposal. How many of you who have read the EAI proposal prefer it to the "hobby class license" proposal which would still permit amateurs to use the entire 220 band?

Massive CB Antenna Announced

One of the EIA manufacturers has announced a "massive CB mobile antenna" which is guaranteed not to burn out in CB installations.

Photographs Needed

We would like to do some picture stories on the various aspects of amateur radio and would like to have some good illustrations.

We would like to have some good up-to-date illustrations to accompany a series of articles on the various aspects of amateur radio. How about it, you photographers out there, can you come up with some nice 8 x 10 glossy black and white photos showing the following?

1. A workbench with test equipment and tools with a partially built piece of ham gear on the bench.

2. A picture of a shack, complete with operator, obviously a DX op from the QSL's on the walls, neat and using equipment which is advertised in 73.

3. A slow-can television setup, perhaps with a good looking chick watching.

4. A ham-TV station, perhaps some enlarged test patterns on the wall. Could there be a chick here too? A girl makes things look ever so much more fun.

5. How about an RTTY shack photo?

6. There must be a gorgeous looking Novice out there somewhere . . . well, perhaps not, maybe then a Novice shack with a lot of QSL cards?

7. Yes, we need a 2m FM operator, probably in a car with rig showing plainly, and no QSL cards at all.

8. Let's not forget the VHF nut and his barrage of antennas . . . please, a nice VHF antenna picture.

9. Then there is the super DX VHF nut who works via moonbounce . . . dish pictures needed.

10. Club activities should not be forgotten . . . perhaps your club might pose for a big picture! With any luck I'll be able to get this into several magazines and perhaps a booklet or two. You'll all be famous.

11. If anyone can come up with a good picture of a mass of mobiles, whips showing, that could be a winner, too.

12. An interesting hamfest or convention shot showing a lot of hams having fun could be a winner.

13. Have you any good shots of contest operating such as Field Day or one of the VHF contests?

14. What did I forget? You think of it and send in the picture.

Good pictures which are acceptable for publication will bring $15 for the first in a category and $5 for each after that. Good pictures of girls doing something hammy are always needed. Licensed girls pay even more. Beautiful licensed girls pay a premium. Gorgeous sexy girls who are hams could bring you even more than a premium. And, say, don't forget to include a model release when you have people in your pictures.

Audio Amateurs

Those of you who are interested in building hi-fi gear will want to check out a new publication, *The Audio Amateur, 307 Dickenson, Swathmore PA 19061.* Like me, it's thin, but fun.

Mobile Installation

Not many years ago an FM installation in the car was a great big deal. The transmitter and receiver went into the trunk of the car, the antenna took an hour or so to install, the control head had to be mounted up by the driver, and all those wires!

The other day someone temporarily defuncted my Rover 2000TC and I had to change to an Alfa Romeo for a few days. It took about five minutes to remove the two FM units (with amplifiers) from the Rover and about an hour (at the most) to set it all up in the Alfa. Not bad for two complete FM units, one running 100 watts output!

I decided to use the Volvo for a trip to New York so the equipment was changed again, taking perhaps a half hour this time. The Standard 826 and the Regency Transcan went on the glove comparment shelf, the two amplifiers under the seat. We ran heavy wires to the battery with clips and didn't even have to put in new wires, the same harness being satisfactory in all three cars.

The big difference is in the small size of the units and the magnetic antennas which just clamp themselves to the car wherever you put them down.

(continued on page 7)

Building Club Interest

Clubs will die off, given the chance by inept officers. The big problem is how to get them to expand. This isn't really all that difficult if you think of it from the viewpoint of the prospective member rather than as a club officer. The key to getting new members is to offer them fun and entertainment which will make them want to come to meetings and participate in club activities.

Before I give you hints on how to attract members, may I take a moment to give you some good hints on how to kill off your club fast?

1. Rather than have the basic business decisions for the club made by a small executive committee, bring all matters up for discussion and agreement by the whole club. This will greatly entertain everyone by getting them into arguments and fights for hours at a time, frequently occupying the entire meeting period.

2. Exhort members who have shown little interest in coming to meetings or participating in club activities to shape up and stop leaving all the hard work to the little clique which has taken over the running of the club. Make them feel good and guilty about their laziness.

This list could go on indefinitely, but you get the idea.

Okay, now down to business . . . getting members. You are going to keep business out of those meetings as much as is humanly possible, right? You're going to have a nice coffee and doughnuts after each meeting, right? You're going to arrange to have interesting speakers and let everyone know they are coming, right? You're going to have a club bulletin full of reasons why the club is fun, right? You're going to wrack the brains of the elite clique who has taken over the club to think up more and more reasons why hams will have fun at meetings, right? You're going to have things going on that will interest Novices, right? You're going to make sure that the better known and more interesting amateurs in your area attend the meetings and that everyone knows they will be there, right?

Perhaps the idea comes through. You have to sell prospective members on the fun they will have at a meeting. You may find a short interesting film will help . . . a manufacturer of ham gear is often fascinating . . . an RTTY member will often just about break his neck to put on a demo and try to sell everyone his passion . . . ditto slow-scan television . . . and even regular television . . . and watch out for the repeater fiends, they are the most virulent of all and if you give them much time on the program they will have the club setting up a repeater in no time at all . . . and perhaps a repeater is a better club project these days than a club station? . . . and what club hasn't at least one member who has been traveling and can't come up with slides of Tonga or some damned place to make everyone else eat their heart out . . . you should have at least one inveterate builder who can take at least part of a meeting to show his latest TTL logical QSL-answering automatic transponder and keyer . . . and all this can be whipped to a frenzy of anticipation in that club bulletin.

You don't have a club channel on some band? Maybe on the club repeater? Well? And don't fight it if the SSTV fanatic wants to zip some of his pictures through the repeater now and then just to zing some of the other members into setting up a scanner. Or perhaps the TT nut should have a little time to send some of his diddle-de-diddle over the repeater to another typer. If you get members too excited over these things you may find a second TT repeater being set up for 10–70 and maybe even an SSTV repeater? Not likely.

That club bulletin . . . that is your workhorse . . . use it to let all prospective members know how much fun everyone is having at the meetings . . . use it to make them want to be at the next meeting . . . this is your advertisement to get more members so don't worry about the postage to inactives, if they don't see your ad they'll never come. Can you get each "active" member of the club to accept the responsibility to call one "associate" member (prospective member) and urge him to come to the next meeting? . . . everyone has been asking about the "associate" . . . they all want him to come . . . etc. Of course this all falls flat if the fellow finally comes out of his shell for a meeting and is royally ignored. The chap you see standing over there in the corner is attending his last club meeting.

Collinear Antenna Dimensions

Back in July we ran an article by K6MVH on a two meter collinear antenna. This article created quite a lot of interest in this easily constructed high gain vertical antenna which is so ideal for FM operation.

The antenna article was pretty good with one little exception . . . the dimensions of the antenna never made it to the printed page. That was an editor's "oops." It was particularly an oops for an editor who was printing his own article and who prided himself on being infallible.

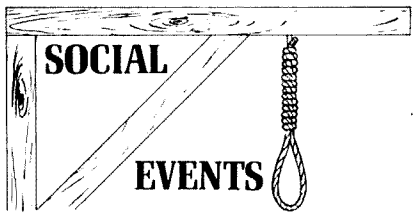
A correction of the oops eventually made it through the mills and, for those who could find it, appeared obscurely somewhere in the pages of fine print. The correction left something to be desired too. Apparently the antenna in question was originally written up in the FM Bulletin by VE3BXA and a bit got lost along the way.

Referring to the 73 Coax Handbook, we find the following dimensions for antennas and coax which are pertinent. A half wave is double the quarter wave dimensions.

Dimensions: Let 146.5 MHz=(a), 222.5 MHz=(b), and 440 MHz=(c). Then the dimensions for a quarter wave antenna would be (a) 20.15 in., (b) 13.25 in. and (c) 6.71 in. A quarter wave of RG-8/U polystyrene coax would be (a) 13.3 in., (b) 8.75 in. and (c) 4.43 in. A quarter wave RG-8/U foam coax would be (a) 16.1 in., (b) 10.6 in. and (c) 5.37 in. Half waves are twice quarter waves.

The Coax Handbook also gives the dimensions for full, half and quarter wave sections for all amateur bands from 80m through 1296 MHz for antennas and coax with Polystyrene, Teflon, Amphenol Polyfoam and Beldem Foam.

The diagram in the article can be deciphered by substituting the numbers under "antenna" in the above chart for (a) and the other RG-8/U numbers for the (b)s. (c) = 2(b).



Some of the PURPOSES of the Institute of Amateur Radio

1. PR for amateur radio to improve the public image of the hobby.
2. PR for amateur radio with members of Congress.
3. Encourage newcomers to get their amateur radio licenses.
4. Encourage amateurs to upgrade their licenses.
5. Provide study guides to assist amateurs in upgrading their licenses.
6. Encourage clubs to be started and to grow.
7. Encourage amateurs to build and experiment.
8. Encourage amateurs to try new facets of their hobby.
9. Work with any willing organizations toward a stronger hobby.
10. Encourage planning for the future expansion of amateur radio.
11. Encourage international planning for ITU conferences.
12. Encourage satellite amateur radio communications.
13. Encourage amateurs to take an active interest in regulation changes.

YOU *CAN* HELP! Will you?

The newspages of 73 will carry Institute news to all active and interested amateurs. If you have information on any of the following it will be

(continued on page 9)

GATHERINGS

Fun for all is guaranteed at the Navy-Marine Corps MARS Picnic, Swapmeet, Auction and Hamfest. Everyone is invited to this gala festival of exhibits, displays, and fun. Hourly prize drawings, ladies' prizes, and auction (2 P.M.) are only some of the features of this get-together. April 16 is the date, 10 A.M. is the time, and it's at Adobe de Polomares, Pomona CA.

The Ninth Annual International Hamfest will be held at the International Peace Garden between Dunseith, ND, and Boissevain, Manitoba. The dates are July 8 and 9. Hams from California, Washington, Minnesota, North Dakota, Saskatchewan, and Manitoba have attended in the past for the gathering. How many more places will be represented there this year? Contact Mel McKnight WAØSJF for more details.

In Mansfield, Ohio, the Intercity Radio Club will hold its annual Ham Auction at the U.S. Naval Reserve Training Center on Friday Feb. 4 at 6 P.M. Address of the Center is 170 Ashland Road in Mansfield. Donation of one dollar at the door.

On February 20, the Toledo Mobile Radio Association will hold its 17th annual auction at the Lucas County Recreation Center, Maumee, Ohio. There will be exhibits by manufacturers and door prizes to add to the festivities.

The Playground ARC, Fort Walton Beach, Florida, will host the second annual Florida Boondocks Swapfest on March 19 from 8:00 a.m.–5:00 p.m. at the Community Center on Highway 98. Talk-in stations will be on 94 direct, 34–76, and 3957 kHz. Tickets available from PARC, P.O. Box 873, Fort Walton Beach FL 32548.

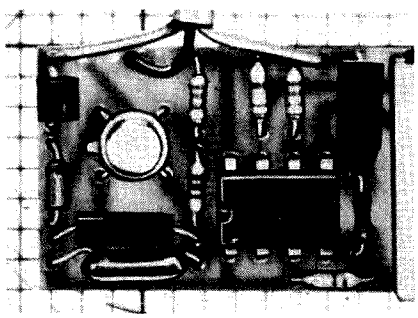
Watch for Special Events Station WY3MCA between January 23–30. This is the Severna Park YMCA ARC commemorating National Y Week. Phone and CW operation is planned on all bands, and a Novice station will be on the air also. Each contact will receive a special QSL.

The Texas VHF-FM Society will hold its winter meeting in Corpus Christi on February 26–27. Saturday's program begins with registration and in the afternoon progress reports from the different repeater groups of the state will be given. The evening offers a technical session that continues until all questions are answered. Sunday will be a variety of business meetings and speakers about aspects

MICHIGAN

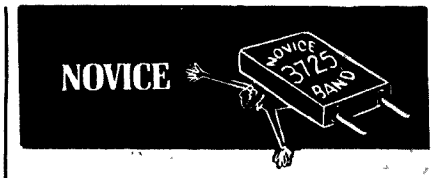
Blossomland Amateur Radio Association presents its annual ham auction, Sunday, March 12, at the Shadowland Ballroom, St. Joseph, Michigan. Doors open 7:00 A.M. Admission $2. Auctioning free. Display tables available with one-half acre under roof. For additional information write: BARA, P.O. Box 175, St. Joseph MI 49085.

CONTEST



The Itchycoo Park VHF ARS announces the second annual World-Wide VHF Activity from 1900Z March 11 until 0300Z March 13. The purpose of the Activity is to promote VHF and to provide a testing ground for new systems during an otherwise low-activity period. To make a contact, exchange call and state. Foreign stations exchange province or country and call. Any amateur band above 40 MHz is acceptable. To score, multiply contacts times states, provinces, and countries worked. A station may be worked once per band. Recognition certificates will be awarded every ham station that meets either of two requirements: fifty contacts below two meters, or twenty-five on two and ten on any higher band or bands. Special endorsements will be given for the top scorer in each call area or country.

Logs should show date, time, freq, state, and call. All modes are acceptable. Logs must be postmarked by April 15, and send them to WA3NUL, Itchycoo Park VHF ARS, Box 1062, Hagerstown MD 21740.



NEW PRODUCTS *(cont. from p. 5)*

The Frequency Modulator works with any of the Communicators. Built-in tone burst is available for use with repeaters. A carrier frequency adjustment allows the frequency to be set exactly. Other modulation, such as FSK, can be applied to the frequency modulator. The unit is priced at $34.50. Built-in tone burst is $10. Communicator model and tone burst frequency must be specified with order. For more information write to *Palomar Engineers, Box 455, Escondido CA 92025.*

TONE BURST ENCODER

Tone burst activated repeaters no longer pose an entry problem to walkie-talkie owners who have the Ross and White model TE-P tone burst encoder. This is a single tone encoder that is field adjustable from 1700 to 2500 Hz. Since most hand-held units are ultra-compact, R & W will handle the installation for a fee, setting the freq to your request. Drop a line to *Ross and White at 50 W. Dundee Rd., Wheeling IL 60090* and tell them what you have so they can quote you a price for the unit and installation.

As Wayne wrote in the December issue, it is kind of rough as a Novice to explain ham radio with a demonstration. Frequently it is a matter of impressing your parents' friends with those electronic gadgets in the basement. Those bleeps and boops are not too intelligible to the average member of the bridge club. Their impression of ham radio depends on you and how you show off what you can do. Here's the way I used to do it, and it has proven to be successful for others.

Tell the listener what has been done, what is being done, and a hint of things yet to be in amateur radio. A little history of amateur radio, with the early wireless experimenters is a good point at which to begin. Only one or two names are necessary, and no mention of spark gap. The fewer technical terms you use, the fewer you will have to explain. Also, you don't look as though you are showing off. Explain a bit about some developments in electronics in which hams have been in the vanguard, such as transistors, computers, television, satellite and moon-bounce. You can touch on the public service aspect of the hobby but do not make it sound as though you personally handle life-or-death traffic every day. In almost ten years of operating, the most urgent message I handled was a mother wanting her son to call home immediately. If you are asked what traffic you have handled, explain what type, if any, or what type you are prepared to handle. Remember that

(continued on page 9)

there are Novice and slow speed nets that you can participate in.

All of this should take about three to five minutes. After you have begun, you can turn on the rig and slowly and absent-mindedly tune around the forty or twenty meter bands, two of the more active frequencies. Next you can explain a little about the licensing requirements and that you are at the beginning step and will soon have a higher class ticket that will permit you to operate without restrictions such as you have now. Now mention a few of them. Show your guests a crystal, how you keep a log, and tune in a few stations for about ten to fifteen seconds each, but move slowly enough so that if one of your guests hears something interesting, you don't lose it. If your visitors are ladies, tune to the high end of twenty to get some of the YLs that often are there. You can explain that there are a lot of women involved in radio and that they are among the more proficient operators. Let them hear Morse code also and listen to a station that is going at about your speed and translate a bit of it. Remember they don't know the code and will hold you in regard as a skilled op even if the station you copy is going at about four words per minute. Compare your speed with a fast CW man and explain that you are not that proficient yet. They will asssume you have false modesty and are really that good anyhow. You have now taken up about eight or ten minutes, which is about all they wanted in the first place. Answer any questions that come up, including the request to call someone.

Do not give the excuse that your antenna is down or that no one is on. Tune up your transmitter (into a dummy load, of course) and explain that you are tuning up. "What's tuning up?" someone will ask. Tell them that it is like getting the air and fuel mixtures right when tuning up a car, or getting everything set so that the final tube will like the electrical qualities of the antenna. Finally, the moment everyone has been waiting for . . . a real live broadcast from a radio ham. Tell them you will call CQ or answer one if you hear a loud one. Tell them also what CQ means. Inform the awe-struck voyeurs that you probably will not make contact due to the odds against it happening just when you would like most to demonstrate (Murphy's Law). This way they are only a little disappointed if you are right, and really ecstatic if you get someone. Look calm if you do get someone.

While the other guy is giving you a call, explain what you will say, but keep it short, like perhaps RST, QTH, and that you are showing off. Do pretty much the same if you can operate phone, and on your next transmission give the mike to someone who wants to talk. NEVER force anyone to say anything over the radio if they don't want to. Translate what the other ham says as he is saying it (it's better to copy in your head than on paper). Answer any questions the ham might have in your next message and tell him that you have to go back to your guests. Of course, you have told your guests that you'll say this and often they'll say, "Oh, no. Don't stop on our account. You go ahead and talk with him and we'll go back to playing bridge." If this is the response, you need not sign, but can carry on as usual.

If you didn't get a reply, they'll still excuse themselves so that you can be disappointed and embarrased in solitude; but you expected no reply anyhow. So you can call CQ again on your own time. If your guests stay on, talk some more with them and answer questions. The shack will speak for your prowess as a radio experimenter so there really was no need to prove it other than to show off a bit and to inform and impress the visitors. Your QSLs on the wall, the DXDC certificate, the map with the colored-in states all attest to your ability. A neat shack is more sophisticated than the rustic rat's nest, and it shows a professionalism that the latter lacks.

Your station is a reflection of you, the operator, and how you keep it organized reflects on you. Your presentation of what ham radio does is the impression you leave with your guests and friends. If your license prohibits you from making a remarkable demonstration, make it a good one instead.

. . .K1NUN

de W2NSD *(continued from page 7)*

of value to all amateurs if submitted for publication.

a) Events where amateur radio has helped save a life or helped someone in trouble.
b) Legal or other possible threats to amateur radio.
c) Events where amateur radio has made the national news.
d) Legislation pending of interest to radio amateurs.
e) Sources of speakers, films, etc., for radio clubs.
f) Hamfests picnics, conventions, dinners, exhibitions, etc.
g) Lists of stolen ham gear to help dealers locate missing equipment.
h) Stories of amateur radio demonstrations to government officials.
i) DXpedition stories and pictures which would be of general interest.
j) Certificates being made available.
k) Contests of general interest.
l) News of unusual feats in amateur specialties such as SSTV, RTTY, ATV, etc.
m) Satellite news in as much detail as possible.
n) User reports on new equipment, good and bad.

Rather than set up an expensive system of issuing membership certificates and pleading for money and members, 73 is funding the operations of the Institute of Amateur Radio 100%. This includes all functions of the Institute such as the issuance of certificates which make operating a lot more fun for the newcomer to our bands, the sending of selected copies of the Amateur Radio Newspages to all members of Congress to help promote amateur radio where it really counts, in Washington, encouraging the publication of the most extensive and complete license study courses written specially for each grade of license exam, the publication of material to help clubs to be formed and grow, the publication of state-of-the-art construction articles to help amateurs have the fun and education of building their own equipment, the supporting of DXpeditions, the supporting of amateurs in legal difficulties which could have an effect on all amateurs, providing speakers and support for important amateur hamfests and conventions, and a myriad of other projects.

With YOUR help amateur radio will be bigger and stronger . . . and MORE FUN for everyone! Please go that little bit extra and help.

Inexpensive FM Crystals

The Ed Juge ads tell us that Ed is carrying crystals for the popular FM channels in the 6 MHz and 12 MHz ranges for transmit, which should work with the Regency, Simpson, Drake, Telecomm, Tempo, Gladding and Sonar. The receiver 45 MHz crystals should work in all the popular ham rigs except the Gladding, Standard, and IC20/21 units. The remarkable part is his price of $3.95 each! This is cheaper than even I can buy them from the crystal manufacturers, and I've bought over $500 worth so far to help me test out the many units which I've reported on in 73.

. . .W2NSD/1

GOOD GRIEF, WE MADE A BOOBOO (ERRATUM)

On p. 43 of the December issue, there is an error in the diagram of the power supplies for the Morse Memory. The middle bridge rectifier of the three should have the diodes all reversed, and the NPN transistor should be a PNP. This will give the −9V dc indicated.

LETTERS

ou goons don't ever proofr
lousy
bunch of rocks
you ignored my comments in
I insist that you print ev

About a month ago I decided to get on 40 SSB and try to carry on a *conversation* with somebody. I was really determined. After trying every approach possible (almost), I determined that it was not as easy as I had expected. Band condx were good – perfect for a good conversation. After a couple hours, I gave up.

I think that, as you said, there is no simple solution. I think that the problem is even deeper than you suppose. QST has had numerous editorials and articles on this very problem for years. I would be willing to wager it will get worse before it gets better.

New York City can be the loneliest place in the world with all its people. I think if that changes, our problem on the ham bands might change; but probably not before then.

Well, the idealists that we are, we can't give up. Keep trying to crack away at our shells!

Re getting rid of phone patches – as you can get from my prior statements, I don't feel that simple solutions will do any good at all. I think that stateside phone patches are a good way to "impress relatives." Often, I run a phone patch for just the sake of showing a non-ham friend how the radio works. In that way, these are meaningful contacts. Nets are okay if they serve a purpose (such as WCAR). Nets, formed just to talk, sometimes produce more meaningful conversation than single QSOs.

Gregory Ginn WB6ZNM
Hemosa Beach CA

Sorry about the late renewal but if I get one of those books I think it was a good idea to wait. You are not the only people with money problems. Maybe you should have a student rate.

Your magazine is pretty good except sometimes you should have articles explaining things that some of us don't know too much about. Like the propagation chart in the back.

Another thing is some people think that 2m FM is getting a lot like CB. I tend to think along those same lines, since you never see construction projects (except for antennas) for it. There also seems to be a lack of interesting things happening in it. In HF just working distant places seems to be enough, or ragchewing with another state, but on 2m it seems to be just a telephone service. OK for people who want it but I like doing something spectacular with my license like building something or talking with some distant person with a rig I had something to do with. Plugging it into the wall and working someone just doesn't thrill me. If you could do something about that I would be very interested and I am sure others would too. There are also higher bands like 220 and 432 that shouldn't be left out.

Ken Dragoon
Portland OR.

In regard to the article in your December issue on a "Morse Memory;" I think I can suggest an improved method of programming the device; if the user has a keyer that functions by counting down from a clock, he could add the output with the clock base to provide the desired input code. This would facilitate rapid reprogramming of the memory and greatly extend its usefulness.

John McHarry WA9FCH
Wappingers Falls NY

Could not resist writing a short note after seeing you listed as NH LocSec in the July/August Mensa Bulletin. I've been a member of Mensa (and, while it existed, of MM) for several years. Often wondered how many hams were members of Mensa, but didn't even know one more before. Can you shed any light on the subject?

I've not been too active in local groups – move around too much (am now a Major in the Army), and often end up where local groups aren't. Have written for 73 (May 69), as well as the competition. Must confess that, after some bad experience with CQ (Sept. 68) I have decided I much prefer your editorial policy. Unfortunately, a year in Viet Nam, and my current efforts to get an MS in Computer Science, have interrupted my writing for a while. The ideas are piling up, though, and next year may be a different story.

Possibly a short explanation and query in 73 might unearth a few more HaMs (or produce a few more).

Dale E. Coy W5LHG
Rolla MO

Amateurs interested in joining Mensa, an international club of people in the top 2% IQ, should write to Mensa, 1701 W 3rd St., Brooklyn NY 11223 for details. There are quite a few hams in Mensa, by the way. I dunno why.

I recently visited India on a business trip and had the good fortune of being able to meet some of the ham fraternity in Madras, India.

Back row, left to right: Rao, Venkata, Gokula; Front: Chauman VU2MZ, Bernie W9HTF, Savoor VU2RS and George VU2GF.

The Madras Amateur Radio Society held a special breakfast meeting for me where I got to meet and talk with them. They appear to be in favor of most of your stated ideas concerning amateur radio and feel that 73 is the most useful ham magazine for their purposes. They are a fine group of hams and SWL's. The 20m band is open to the U.S. from 1030 to 1230 GMT, and they are on 14.1–14.2 MHz and welcome DX break-ins. If the band is opened to U.S. hams below 14.2 they will move lower in frequency. Most operation is AM and CW but Savoor, VU2RS has just acquired a Yaesu and is on SSB. Chauhan VU2MV recently obtained a model 19 Teletype unit surplused by the Indian Army and hopes to be on RTTY soon.

By the way, they can obtain a reciprocal license for U.S. hams in 2 days.

Bernard Ostrofsky W9HTF
Gary IN

Articles on TTL logic, like the one by Darrell Thorpe in the December issue, are needed.

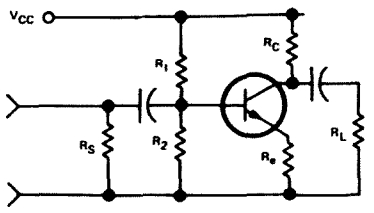
Please print some more of these. You might start with one on how to make an input circuit for a counter that uses TTL.

Present prices on these IC's must make them about the hottest item around.

Eugene H. Beebe W6SSB
Long Beach CA

DEPT. OF AMPLIFICATION

Carl C. Drumeller recommends in his article "Biasing the Transistor Audio Amplifier" in the November '71 issue of 73 that the "cookbook" method of amplifier design be dropped in favor of what is essentially an intelligent cut and try design procedure. In this letter I will expand some of the author's comments on common emitter, CE, amplifiers and suggest a design procedure that is a little more scientific than "cut and try."



The author correctly states that "Active devices, whether vacuum tubes or transistors, vary in characteristics from one sample to another," but for transistors used in low level audio amplifiers usually the only important parameter that varies widely is

beta, or the forward current transfer ratio. Alpha, or the common base current gain can usually be assumed to be 1.0, and the forward biased base to emitter voltage for a silicon transistor is generally about 0.7 volts. The key to good design is to design circuits that have low sensitivity to beta, then virtually any transistor of the correct polarity and adequate voltage ratings will work.

Thermal runaway should not be a problem in low level CE amplifiers. For thermal runaway to occur in a circuit, an increase in collector current must result in an increase in power dissipated within the transistor. If the transistor in the CE amplifier is biased such that V_{CE} is less than ½ V_{CC} the reverse is true and thermal runaway can't occur.

I disagree with the philosophy of tailoring the bias network to an individual transistor for three reasons. First, even though replacement may be seldom, it is quite a bother to redesign each time. Second, the breadboard circuit usually winds up in a box of some kind where things may get a bit warmer than out on the bench. That carefully tweaked circuit may be a bit off as the temperature goes up. And finally, the gain that results from a cut and try procedure will vary widely. In a feedback circuit this could be disastrous, turning an amplifier into an oscillator. Knowing what gain you will wind up with is usually better than extracting that last dB of gain. After all, transistors are cheap now. If you need the gain, add an extra stage.

A reasonably easy design procedure that gives good results will be described by example. Part designations refer to the sketch below.

Problem: design an amplifier that will put out 10V peak to peak into a 10 kΩ load. A gain of 5 and an input impedance of 75Ω are required.

Procedure: first pick the supply voltage. Since the output signal is 10V, the supply voltage must be greater than this. Arbitrarily pick 15V.

Second step. In order to adequately drive the load, R_C must be smaller than R_L. Think of the output circuit as a voltage divider made up of R_C and R_L. (Normally the drop across the coupling capacitor will be small) The voltage being divided is V_{CC}. A collector resistor, R_C, of about 1/8th the size of the load resistance will do nicely here. Choose 1.2 KΩ for this example. Needed in the next step is the total collector load, 1.2 KΩ in parallel with 10 KΩ or 1.07 KΩ.

Third, calculate R_e. With a large unbypassed R_e stage gain is very nearly R_{cl}/R_e where R_{cl} is the total resistance the collector sees. This follows from 1, the collector and emitter currents are nearly equal, and 2, the emitter voltage swing nearly equals the base voltage swing. Therefore in the example for a gain of 5 R_e should be 1.07 KΩ/5=214Ω. Use a 220Ω resistor.

Fourth, for maximum output voltage swing, the quiescent (no signal) collector voltage should be about ½($V_{CC}-V_e$) where V_e is the maximum emitter to ground voltage. There is usually no need to calculate the optimum, as a good guess is close enough. In this example pick the quiescent collector voltage to be 8V leaving 7V across R_C. Quiescent collector current is, therefore, 7V/1.2 KΩ = 5.83 mA.

Fifth step. Since the emitter current is about the same as the collector current, the emitter voltage will be about 5.83 mA X 220Ω=1.28V. Adding to this figure the usual 0.7V base to emitter voltage we find that the base must be biased 1.98V above ground.

Sixth step. The input resistance at the base is about beta times R_e for this configuration. In the example a beta of 50 is reasonable, so the input resistance of the circuit will be about 50 X 220Ω or 11 KΩ, but varying widely from transistor to transistor. To swamp out this variation, let the parallel resistance of the bias circuit be 1/10th of this or about 1.1 KΩ. Equations for R_1 and R_2 to simultaneously put out a desired voltage and have a desired parallel resistance are: $R_1=(R \times V_{CC})/V$ $R_2=(R \times V_{CC})/V_{CC}-V)$

Plugging in R=1.1 KΩ, V_{CC}=15V, and V=1.98V yields R_1=8.11 KΩ and R_2=1.27 KΩ. Choose 8.2 KΩ for R_1 and 1.2 KΩ for R_2. To obtain the desired 75Ω input resistance, putting an 82Ω resistor across the input will suffice.

The size of the coupling capacitors will be determined by the desired low frequency response. Note that the calculation for the input capacitor has been made easier by substantially removing changes in the input resistance caused by variations in transistors. Calculating frequency response is an article by itself, but each coupling capacitor causes a roll-off at $F=1/2\pi RC$ Hertz where C is the capacitance in farads and R is the resistance in ohms that the capacitor sees. For example, the output capacitor above sees 10 KΩ plus 1.2 KΩ=11.2 KΩ.

Understanding the above method may appear to be difficult when compared to the cut and try method, but the rewards are greater. With a little practice you should be able to design an amplifier to specifications in less than 10 minutes.

David L. Button
Medway, MA.

REPEATER CONTEST?

A contest through repeaters? How many repeater operators would go along with it?

Repeaters are set up and maintained for extended local coverage of members using mobiles, portables and low power fixed stations. After a contest or two the big guns of contesting would be on with KWs, 64 element arrays and all the other goodies.

Probably very few repeater groups would be satisfied to sit on their hands and pay the light bill for these people to chat among themselves. After a contest or two there would probably be very few machines on the air during contests.

FM operation has grown because it is informal, friendly and you don't need acres of antennas and kilobucks in equipment to operate satisfactorily.

If we must have a contest let's make it once every five years from 00:00 to 00:15 local time with the top thousand scorers in the last contest ineligible to compete in the next.

Don Norman K8LLZ
Elyria OH

You have to be out of your tree to suggest a repeater contest!

Max W5ODF
Little Rock AR

I read your little suggestion (in the current 73) about having a repeater contest. My vote is NO! I knowthat controversy builds circulation,*(1)* and I'm all for your magazine, but please lay off this one. I know that the ARRL is all for lots of stupid contests, but I really thought more of you.*(2)* My thinking? Repeaters are for communications, not competition.*(3)* In areas having numerous repeaters with 50 to 100 watts output, the repeater owners and operators would become egotistic enough to wish to up their power (as a "public service") and help that distant signal many miles away to hear much better. While this goes on in contests, the man who has an emergency on his hands get covered in the general foulup. Without having contests, when skip appears, the distant station works a few through several repeaters and stands by while others work distant stations. Courtesy is the rule, not something exceptional. Let me say here and now, I have never heard any contest on any band where courtesy was present except in nearly microscopic amounts, well hidden in the din. I have quit contests, but I'll listen if you have found some polite ones.*(4)*.

Don Chase WØDKU
Wichita KS

1. To the contrary, controversy cuts down on circulation. You have fallen for a big lie that one or two of the other magazines have perpetuated as an explanation for 73 telling it like

it is. Every time 73 is controversial the circulation takes a dive and ads fade away for awhile. It takes a lot of social conscience to print anything controversial when the reaction is going to be a loss of money. 2. Sorry to disappoint you, but I have always enjoyed contests. I agree that many of them are terrible and I have controversially written just this opinion on many occasions. The reason that 73 has NEVER run a contest is that I have yet to think up a contest that I would be proud to run. This does not mean to me that such a thing is impossible, only that it is difficult. Perhaps you are right and it is impossible to run a good contest. 3. Repeaters are for fun, in any way that is legal. If communications is fun, then let's use them for communications. If "communications" means I shouldn't rag chew, then we need a new definition of communications. If it means no contests then you need to look up the word. 4. I'll go along with that. What do you suggest?

Wayne

A contest is supposed to be a test of operating skill. From your SCR-522 days in Brooklyn and even from operating the powerhouse on 73 Mountain, I am sure you remember a really good operator had to be able to hear signals, find clear spots to call CQ, hear the guy he was trying to work through several other signals, remember which way to point his beam for the rare sections, tune across the stations already worked, and so forth. How can he do these things with strictly crystal controlled operation with omnidirectional antennas? Plus which, on FM you usually hear only the loudest when there are many signals close to the same frequency.

Practically all FM channels and repeaters have been set up to provide a ready means of communication of relatively unimportant first party traffic plus their incidental usefulness for minor emergencies. A general emergency, or substantial message handling, as on the lower frequencies, would create havoc such as used to occur on the "6 meter" MARS channels when E skip would unexpectedly combine 2 or more nets. Widespread contest operation will result in the same thing with not even the repeater frequencies being safe since all the contest station need do is transmit on the repeater output frequency and listen (if he's honest) on the repeater input frequency to get around the rule against repeated signals. Imagine what it will be like when all the guys like me who prefer to leave the FM guys in their own world, are forced by competition to "go FM" to have any chance of ever again winning a contest. If I do, it will be with high power, a big rotatable beam, and crystals for every imaginable frequency.

Finally by your own definition, contesting or FMing or whatever is supposed to be fun. I do not consider it fun to brow-beat a VHF sweepstakes contact exchange out of some guy who just wants to know how to get on Interstate 95, South, nor do I think he gets much pleasure out of it. Those who want to work contest have tunable gear for CW, SSB, etc. in the first place, let them use it.

Terry Banks K3LNZ
Washington DC

Well, Terry, I agree with most of what you say. It has been my experience, though, that FM'ers do seem to enjoy giving a fast contest contact to those mountain-top stations that set up to work them. In point of fact W1DC sets up on top of Pack Monadnock for the ARRL VHF contests and, last year, made nearly as many contacts on 2m using FM as all other modes combined. I heard few gripes. Obviously it could all get badly out of hand.

Wayne

GOOF DEPT.

As an avid reader of 73, I enjoy your magazine immensely and look forward to every copy. I find it very informative in just about every mode of ham radio. However from time to time I do notice errors in some articles, and in most cases, corrections to those errors in later editions.

I would like to point out 1½ errors in your Dec. '71 edition.

Error Number ½ appears on page 19, paragraph 2, where it explains the function of a nand gate. It is stated that "when all inputs are Logic 0, the output is Logic 1." This is a half correct statement. It should read that when *any one* or all of the inputs are Logic 0, the output is Logic 1. I will therefore only credit you with ½ an error. Hi!

The other error appears in the article entitled, "Morse Memory," on page 37. In reference to Fig. 6 on page 44, it shows that the outputs (pins 10 through 13) of A11 and A12 are connected to the inputs (pins 1 through 6 and 11 and 12) of A7.

However, in Fig. 2, page 41, A7 identifies a memory device, and the gate that A11 and A12 are fed into is unidentified. This caused some confusion when trying to follow the circuit when relating to Fig. 6.

Perhaps a correction will clear this up for readers that are confused, or am I the only one? Both articles, however, even with the 1½ errors total, still rate an A+. Would like to see an article on the Hal Devices Teletype CRT Readout Device or whatever they call it. How about it?

Al Bratz WA8YNH
Dayton OH

We made those errors just to test you, Al. Can any of our readers tell us more about the HAL machine?

BOUQUETS

I ordered the 30 back issues of 73 for $6 I found advertised in the June issue of 73. I've been QRT for three years and I used them to ease me back into ham radio. They were DYNAMITE! 73 is much better than ** and I won't even mention that funny "street" magazine.

John Phillipp WB2HYI
Brooklyn NY

On page 2 of the November issue, it is asked if any readers have run across the number 73 anywhere interesting.

I am a radio operator in the Canadian Armed Forces serving in the Submarine Service. Halifax is the home-port of the three submarines serving on the Canadian East Coast. One of them, the "Onondaga," bears the number "73" on its hull. I am sending a picture of it taken when the submarine was on the synchrolift.

The other two submarines are the "Okanagan" (74) and the "Ojibwa" (72). Since I volunteered for submarine service I served on all three of them. The Okanagan is the only one with an amateur station license at the present. The call is VEØNS and is being operated by Bob Forbes VE1AAU and Jim Guilford VE1ANO. I am now serving on the Ojibwa and she might be getting a station license in the near future, so I'm looking forward to operating VEØ .

When the submarine goes deep during a QSO, I have to QRT and close down. There isn't much I can do down there except to sit back and read a few back issues of 73. So, if you stand by, I will QRX when the submarine goes back up to the surface.

Do you believe in love at first sight? I didn't until I looked at the front cover of the November issue. I got a few centerfolds of Playboy hanging on the radio shack walls but I think I will replace them with the January, March, April and November front covers of 73. Keep making the same type of covers and I might become a life subscriber to your excellent magazine.

Donald J. Courcy VE1AKM
Halifax NS Canada

Much thanks for the new format. No more swinging mag to read. Now try a little larger print on the newspages even if you sacrifice some of the "Slum Gullion."

Lee J. Delworth WB6RDW
Anaheim CA.

Do not exactly know if you want a letter from a simple SWL or not – but I do so much enjoy the letters in your magazine that I want to say a word or so.

Now, my good friend WB6DGJ – (darn Good Jim) Myers has urged me and done his best to get me to get a license – learn the code and so forth, that I am ashamed of myself for not doing that. Jim is too good a friend to tell me that I'm just too lazy, but it's a fact.

Let's go way back to 1920 – that is when I first got interested in electronics, or wireless as it was in those days. I was born with a strong desire to become an electrician, and of course the urge, augmented by a magazine

:alled the 'Electrical Experimenter' ielped to push me along. In those lays, a WD11 was quite the thing, also he UN199. My friends were anxious o have a wireless set to listen to KDKA in Pittsburg, and the other tations who came along, slowly, SO, I built sets for them, and today, a friend of mine in Grandview, Washington has put one of my old sets in a nuseum there – haven't seen it yet, but I'm sure it is authentic, with the old horn speaker and the breadboard chassis with a hunk of Bakelite for a panel!!

Today – Pity is: I have an SB31 0 hat I built myself (bless Heathkit!). It gives me much pleasure – the hams but in the Pacific in the Micronesian net make me drool each night after I get home from managing the biggest theatre in Northern California. The shortwave stations from all over the world come booming in, and I try to ell myself that I am happy, yet knowing that if I ONLY had the guts o sit still long enuf to learn the code, 'd be one of them.

Your magazine is the best of the bunch – which of course you know. Old 'Never Say Die' is a good editor! I only wish I could contribute an article worth reading.

Art Warner
P.O. Box 2511
McKinleyville CA 95521

Will someone PLEASE help Art to get his ticket!

Congratulations on the publication of the 135th issue of 73 Magazine! Along with Ralph Nader and Wally Hickel, we have you providing reading material for hams with an IQ above 100. Fortunate for us . . .

Your editorial covers "meaningful" contacts quite well; that is a major problem and perhaps one reason why so many of us have long periods of inactivity, or, limit our contacts to a few friends around the country/world primarily.

As to phone patches, I think that is one area where the hobby fulfills the public interest area of licensing amateurs or other radio services. Especially, the patches for overseas military personnel.

There certainly does seem to be a "Vast Wasteland" out there . . . Best wishes to you and yours for a happy holiday season and a successful 1972.

Harlan D. Marcus W5MDT
Dallas TX

Have had tremendous response from advertisers I requested info from. Your consolidated request form for advertisers is a real winner!

John Andrews WB5ETV
APO, NY

I'm currently in the Marine Corps, unfortunately being hospitalized in the U.S. Naval Hospital Camp Lejeune NC. I just got back from the Far East and am a little behind in my reading. However I just completed your Oct. '71 issue and must say that your article written by John Campbell W2ZGY "How to be an Amateur," is one of the most inspiring and motivating articles yet. Bravo – it was well written. I enjoy 73 Magazine much more than its competitors which I also subscribe to. Each is good, but your variety of topics and contemporary technical articles have made your magazine worth more than the price on the front cover. I even look forward to the front cover for its art. The entire October issue is marvelous, the articles by Jim Ashe W1EZT, Bob Cooper W5KNT, H.P. Fischer VE3GSP, W. W. Davey W7CJB and others in the October issue and hundreds of amateurs like them in each of your issues has greatly added to the success of your (OUR) magazine. I'm finding myself addicted to 73 and I greatly enjoy the high! Congratulations on a job well done.

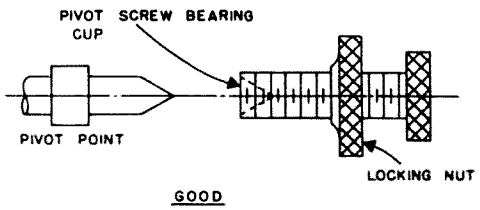
TUNING Mr. MORSE'S KEY

Since every license holder has at some time done a stint of key walloping, it might be assumed that we are all completely familiar with the beast. In fact, a recent study of some of the most comprehensive books dedicated to our hobby revealed almost nothing concerning the care and feeding of the key.

However, an evening spent listening on the CW bands will prove that the 'glass arm' is still with us, indicating that the selection, adjustment and operation of the familiar key may have well become neglected among all the other technological advances. If you are a regular habitant of the CW bands, or perhaps a member of a high speed traffic net – read no further. But if you are a Novice, or an oldtimer getting reestablished on the key, some of the following may be helpful

The humble telegrapher's key has gone through an evolution emerging in many forms some of which have already become obsolete. Today the three basic types found in ham shacks are the straight or "manual" key; the "bug" or semiautomatic key; and the electronic key.

Straight Keys



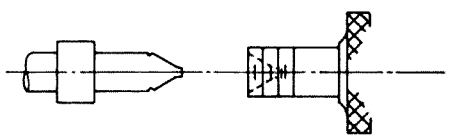
The popular American key is most generally used by hams for manual operation, and permits the greatest ease of operation. The pump-handle key, beloved by European and some oldtime Navy operators has all but disappeared. The former is characterized by wrist operation, while the latter, mounted at table edge, was arm operated. So if you have one of these relics from some surplus buy, keep it as a conversation piece or donate it to the Smithsonian.

If you are in the market for buying a straight key, invest wisely and buy the best available. Many of the inexpensive varieties, available for a buck or two, may be fine for Boy Scouts to earn their badge, but will not guarantee lasting satisfaction.

The essential requirements of a good key are first quality material and construction, including friction-free pivot bearings, low resistance corrosion proof contacts, smoothly adjustable return springs, and well designed balance. There are a number of manufacturers that have been producing such keys for generations, and their products are well worth the cost (upwards of $10).

If you have on hand a good key, it is worth a little time to make sure it is correctly adjusted. Even if the key is brand new, contact spacing and spring tension will have to be set to suit your fist. Disassemble the whole thing, being careful to note how the bits and pieces have to be reassembled, and give everything a good cleaning. Use metal polish to brighten up

the base and arm. If yours has a black crackle paint base, an old toothbrush and a little detergent in warm water will get rid of the dusty appearance. Examine the pivot points on the arm to make sure they are smooth and undamaged and that previous overtightening hasn't deformed the points or the cups in the bearing screws. See Fig. 1. A jeweler glass or one of those hand microscopes for inspecting phono pickup styli is handy for this examination. Check the contacts, and if they appear dark and oxidized, a few *light* strokes with a burnishing tool (Walsco type W529 or equivalent) will put them in shape. Do *not* use a file, even of the spark plug cleaning variety.



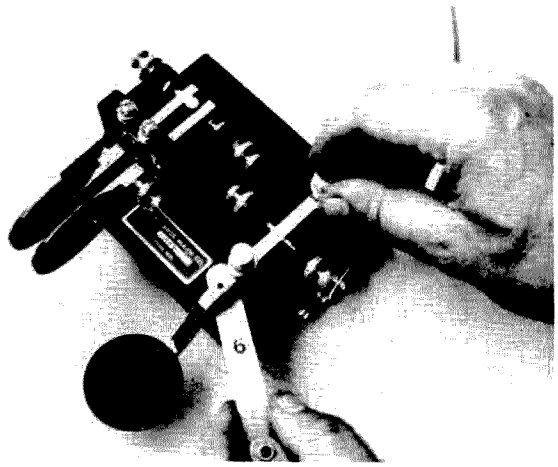


Fig. 1. Key adjustment.

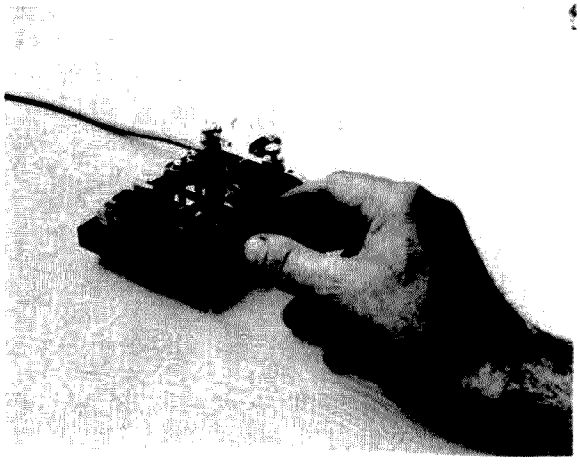
Reassemble the arm, pivot screws and spring loosely, adjusting each of the pivot screws until the contacts are centered. *Very gently* turn both pivot screws clockwise, until you feel the pivot points just bottom in the cups. Do not tighten further or the points may be damaged. Tighten the locking nut on one pivot screw, while holding the screw stationary. Back off the other pivot screw about 1/10th of a turn and similarly tighten its locking nut.

Now adjust the rear stop screw for proper contact spacing. What is proper is largely dependent upon your fist and speed of operation. Slower speed, larger spacing, and vice versa. About 0.005 in. has been found appropriate for moderate to higher speeds, but if you are a slow sender you may find as much as 1/16 in. desirable. Using a feeler gage to measure the contact spacing best suited to you is a good idea. You can then always quickly reset the spacing after some future disassembly. Just remember that too wide spacing will limit speed, while too close spacing may affect the intervals between characters.

Adjusting manual key contact spacing with feeler gauge.

Finally adjust the spring tension to your liking. A good method is to send a series of dits at a comfortable speed, while slowly advancing the tension screw clockwise. You will find a point where the spring tension counterbalances wrist movement, and the arm returns easily without requiring excessive depressing action. At this point the string of dits should be almost effortless. As with contact spacing, so with spring tension, and some final compromise between both may be necessary after a little operating experience. Too strong a spring tension will result in rapid overtiring of the wrist and forearm muscles, while too light tension will require lifting the wrist, and eventual stumbling over characters.



No dissertation would be complete without a few words on proper operation. First, the key must be mounted on a heavy base that won't slide around, if not actually screwed to the operating table. If yours is mounted on a base with rubber feet and it still tends to "walk" across the table, try rubbing a little beeswax on the rubber feet.

The key should be positioned on the table so that the entire forarm can lie comfortably on the operating surface. If

your table is too narrow, try sitting sideways to the table to properly position the arm, which under no circumstances should have the elbow or part of the forearm hanging over the table edge.

Semiautomatic Keys

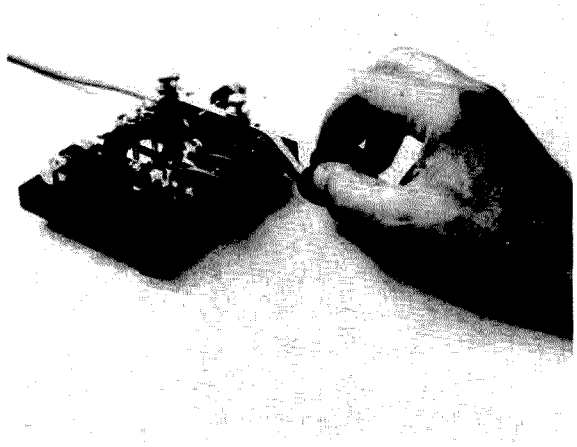
The venerable "bug" key has long been the favorite of the higher speed operator, particularly for use in excess of 18–20 wpm. It hardly seems necessary to mention that no one who cannot send 20 wpm on a straight key should attempt operating with a bug. However, there are some who apparently feel that such an endeavor will help to increase the speed they cannot accomplish on the straight key. Nothing is further from the truth. Most bugs have mechanical dit speed adjustments which are difficult to set below the equivalent of 15 wpm. The characteristic result of sending 10–12 wpm, is complete unbalance in the dit-to-dah ratio, which can be pretty unintelligible to the fellow at the receiving end.

Correct grasp for manual key.

The bug employs a vibrating spring attached to the horizontally moving arm, to produce a series of dits when the paddle is depressed to the right by the operator's thumb. Dahs are made manually be depressing the paddle to the right with the second and third finger, as with the straight key.

All the factors previously stated about selection, inspection and maintenance of a straight key apply equally to the bug. A good quality bug costs from $19 to $30 (more if you like to dress up your shack with a little gold plating).

If you are reactivating your old bug, or have obtained a second hand one, submit it to the same kind of disassembly, inspection and cleaning recommended for the straight key. Be extra careful to take note of how the pieces come apart, particularly with regard to insulating bushings, washers and springs, which can take on the aspect of a Chinese puzzle come reassembly time. Keep small parts in a plastic tray.



The tricky part is adjusting the paddle movement and contact spacing. Start first with the dit action, and adjust the left stop screw for the amount of dit-paddle depression you feel suitable. Just what is suitable is again individual, but bear in mind that too much will affect speed, while too little will give trouble with correct spacing. Some correction is likely to be required later.

Now adjust the right stop screw for an equal amount of travel of the dah paddle. Once you have the right-left paddle movement adjusted, tighten the lock nuts.

To adjust the dit contact spacing, first hook up a code practice oscillator or ohmmeter to the key terminals. With the dit paddle fully depressed, wait for the armspring to stop vibrating and become completely motionless. Then slowly adjust the dit contact screw until it just makes electrical connection with the spring contact, as evidenced by the oscillator or ohmmeter. Carefully tighten the locking nut without changing the screw setting.

Now try out a string of dots with the oscillator, having set the spring weights for slowest speed. The dits should sound about equal to their intervening spaces. If the dits sound clipped with overlong spaces, advance the stationary contact screw about 1/8th of a turn, and repeat this until the dit-space ratio is right. If your shack sports a scope, it can be a great help in observing the correct ratio by setting the horizontal scan rate to a slow sweep. Likewise, if the dits are overlong, and sound blurry, retract the contact screw 1/8th turn at a time until proper ratio is achieved.

Since the dah stop is usually also the dah contact on most bugs, initial adjustment has now been completed. And small

Correct grasp for electronic or bug key paddles.

adjustments of paddle travel and contact spacing, with intervening periods of operation are better than making wild changes that cause you to lose track of where you started from. Also, if you change the dit-paddle travel, it will also be necessary to reset the dit contact spacing..

Adjusting the left and right paddle return springs can be a bit tricky in models that have two such springs, but basically the same rules apply as for the straight key. Just enough tension to return the paddle snappily without requiring excess effort to depress the paddles.

After setting the bug to your liking, adjust the speed weight(s) for a dit speed equivalent to your comfortable operation. Then try sending a series of PARIS and ISH5. Just remember that a dah is equal to two dits with one intervening space (or three dits with no spaces), and only your manual skill can apply the correct ratio dahs to the mechanically produced dits.

Electronic Keys

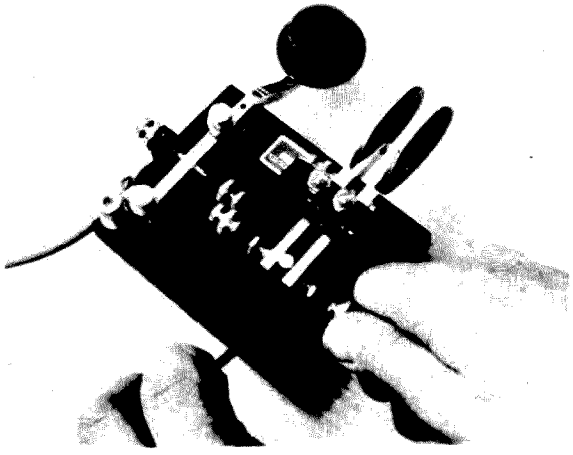
Nothing has done more for effortless high-speed operation than the advent of the electronic key. While the same rules apply to perfecting straight key operation, advancement to the electronic key may be easier than to the mechanical bug. This is because many models can be set for as slow as 10 wpm and are less dependent upon operating skill for correct character ratio.

Early models took considerable skill, since completion of each dit and dah was dependent upon the operator holding the contact closed for the proper period, and early release would clip the character. Contemporary keyers all have self-completing features that insure that a full dit or dah is completed once the contact is closed.

Since the electronic key comprises two basic parts, the mechanical paddle and the associated electronic circuitry, the two will be considered separately. In many instances the two are packaged separately, and connected by an intervening cable, but in some recent commercial models the paddle movement is built-in to the electronic unit, such as in the Heathkit Model HD-10.

The mechanical paddle used with an electronic keyer closely resembles the bug, but lacks the dit-producing spring movement, and has instead a second pair of stationary but adjustable contacts to activate the electronic circuitry. This type of key itself breaks down into two basic types, depending upon the type of circuitry it is intended for use with. The simplest type has a single moving arm, like the bug, mounted on a pair of pivots. A more complex version has two independently pivoted arms, with individual paddles mounted close together, each being capable of simultaneous movement. The latter type of key is used with electronic keyers that automatically generate dits when the left paddle contact is closed and dahs when the right paddle contact is closed. The twin arm key can also be used with this type of circuitry, but is really intended for use with more elaborate electronic keyers that produce alternating dits and dahs when both pairs of contacts are closed by squeezing the paddles between thumb and fingers. This is known popularly as squeeze-keying, and reduces wrist movements required for sending given characters.

As for example: the letter C requires four independent wrist movements, one dah, one dit, one dah and one dit. With squeeze keying the right paddle is depressed for the first dah, and then held while the left paddle is depressed, so that both paddles are squeezed, producing the dit-dah-dit portion of the letter. Thus only two paddle movements are required for the



letter C, instead of four with the simpler electronic key. Note also that this requires independent finger movement, rather than straight wrist action.

Apart from the independent arms of the squeeze-type key, mechanical assemblies are otherwise the same, and previous recommendations for inspection, cleaning and adjustment of pivots apply. However, one further adjustment is worth noting – that of equal contact spacing and paddle travel in both directions.

There are a number of electronic type paddle-keys available on the market, costing from $15 to $20, independent of the electronic keyer.

Now to consider the electronic keyer itself – the circuitry part which produces those flawless dits and dahs. Here the problem is somewhat more complex with the different features offered.

Early keyers provided individual controls for speed, ratio, and weighting adjustments. This may seem nice, but getting ratio and weighting just right can be tricky. Moreover, some circuits require resetting ratio and weighting whenever a major change in speed is made – obviously a disadvantage. Logic circuitry used in late units permits inclusion of a single control for speed, with ratio and weighting always being perfect whatever speed is selected. Ony excellent version of this type which you can build yourself is the Micro-TO Keyer by K3CUW (QST, August 1967 and ARRL Handbook 1968).

Adjusting electronic key contact spacing with feeler gauge.

You can have the **TOP F.M. SIGNAL**

with our base station antenna. The AT-2FM offers you 6 dB Gain, 1.5:1 V.S.W.R. (or better) and 3 Mega-Hertz Bandwidth centered around 146.94 Mega-Hertz.

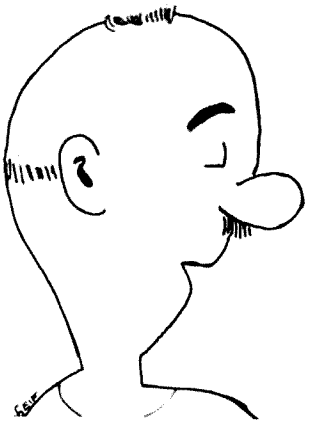
WORLD QSL BUREAU

5200 Panama Ave., Richmond CA USA 94804

THE ONLY QSL BUREAU to handle all of your QSLs to anywhere; next door, the next state, the next county, the whole world. Just bundle them up (please arrange alphabetically) and send them to us with payment of 5¢ each.



Other features include optional full automatic, or semi-automatic (auto-dits, manual dahs as in the bug); built-in sidetone oscillators and speakers; and built-in paddle mechanisms. Many keyers utilize a high speed relay as the output to key the transmitter. Reed relays are commonly used to accommodate speed requirements, but their contact ratings are limited and may not be suitable for directly keying some transmitters (such as cathode keying a high power stage). Other units use a power transistor to perform the keying function, and these avoid contact sticking, and have absolutely no time delay. On the other hand correct polarity has to be observed, as does the maximum current handling capability of the transistor used. All manufacturers specify such constraints in their instructions so take care when buying to select one compatible with your transmitter. Selection of any commercial unit will depend upon the features most desired by the individual after a careful perusal of the manufacturer's specifications.

So whether for you it's manual, semi-automatic, or fully electronic – happy keying!

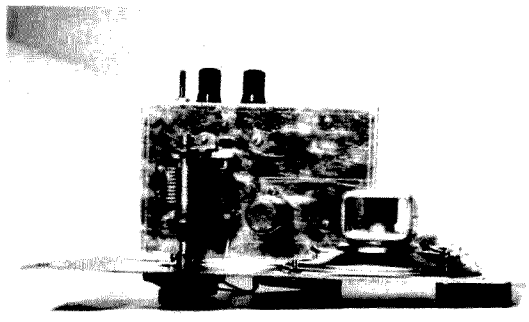
A Solid State High Frequency Regenerative Receiver



Like most hams, the first receiver I built was a one tube regenerative detector. Recently, while thinking back over old times, I decided to try my hand at building a solid state regenerative receiver just to see what kind of performance I could get. While the circuit shown has a few more components than my first receiver with its type 30 tube, it performs much better.

The receiver tunes from 14 to 35 MHz, a range that covers three ham bands, short wave stations and public service frequencies. The detector uses the readily available Motorola HEP 55 NPN VHF rf transistor. The audio amplifier stages are a single RCA 3020 linear integrated circuit. This is an entertainment grade IC and is quite a bargain.

The receiver was built on a 4 x 6 x 2 in.

The solid state high frequency regenerative receiver. A 3 x 5 in. speaker was used. The dial assembly is a Japanese import having a 10:1 ratio.

Top view of the receiver. Note the location of the transistor socket next to the tuning capacitor.

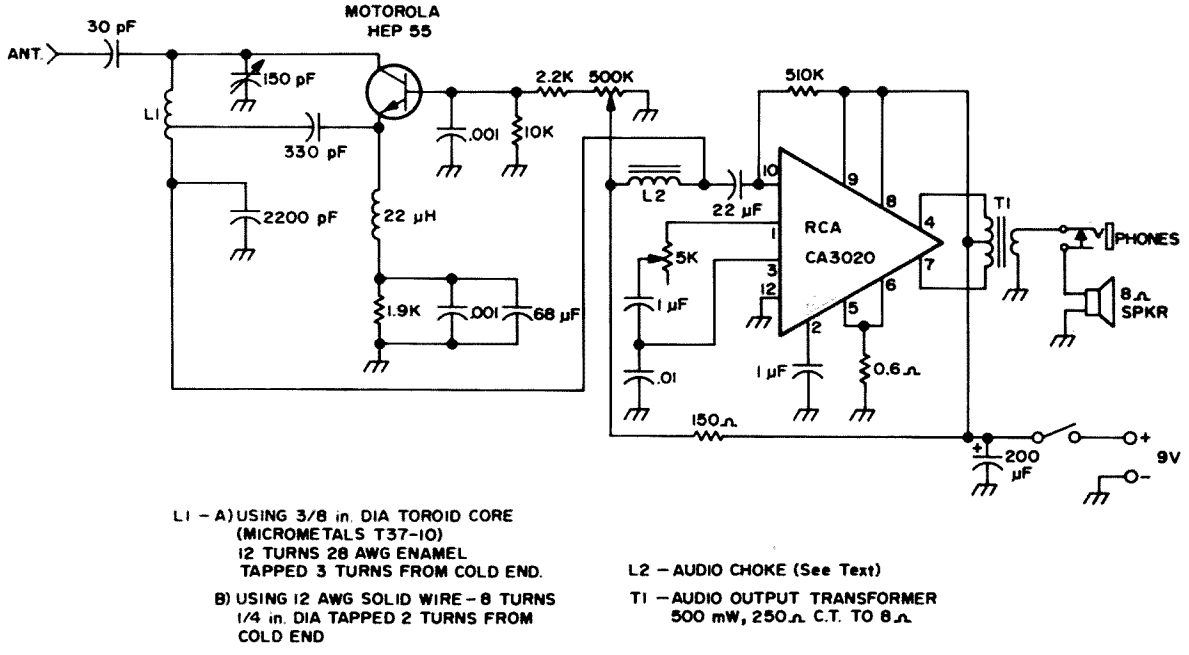


Fig. 1. Schematic of the regenerative receiver. L-1 A) using 3/8 in. toroid core (Micrometals T37-10) 12 turns #28 enamel tapped 3 turns from cold end; B) using #12 solid wire 8 turns ¼ in. diameter tapped 2 turns from cold end; L-2 audio choke (see text); T-1 audio output transformer 500 mW 250Ω CT to 8Ω

aluminum chassis. The audio circuitry, with the exception of the audio choke, was mounted on a 2 x 3 in. piece of vectorboard. The vectorboard was mounted to the chassis on threaded stand-offs. The input audio choke L2, is just the primary of a small 100K to 95K audio transformer. The secondary is not used. Practically any small audio transformer having an impedance in one winding of from 10 to 100K can be used. An alternate approach is to use transformer coupling with a small 20K to 50K interstage transformer.

All of the rf components except the tuning capacitor, are mounted below chassis. A transistor socket was used to permit experimentation with a variety of transistors. Actually a socket is a good idea unless you have had some experience in soldering to semiconductor leads.

You will notice that winding information is given for two different types of coils. The best bet is to use the small toroid cores which are carried by most major parts houses for about 10¢ each. If your local parts house doesn't carry them, use the alternate method. There isn't much difference in performance.

After wiring the circuit, carefully recheck your work. Remember, transistors, unlike tubes, are not forgiving about wiring errors. Now you are ready to hook up the antenna and apply power. Your best bet is to buy a battery holder that holds six D cells. While the idling current of the receiver is only 23 mA, peak currents are in the order to 50–60 mA. The cheap 9V transistor radio batteries aren't designed for this kind of use. Their internal resistance is quite high, and you will probably experience motor boating after short periods of use. The premium grade 9V batteries perform well, but their cost is high.

Connect the antenna. A 40 to 50 ft wire works well. Turn on the power and advance the regeneration control until a clean hiss is heard. Tune in a signal and alternately adjust the tuning and regeneration controls for best reception. A little practice will give you the knack of it.

Performance of this little receiver has been quite good. I have received signals from all over the world, not to mention the fun of listening to the local sheriff's department. Regenerative receivers aren't to be scoffed at for communications, either. I recently worked a station in Colorado (about 1200 miles) who was running five watts and receiving me on a regenerative receiver!

HEADSETS and HAM RADIO

There are several advantages to be gained by using a good pair of earphones in an amateur radio station. I hope this article will convince a few more hams to plug in their headsets and to cut out their loudspeakers.

Most hams operate from their homes and their stations are often set up close to where others are conducting activities completely unrelated to hamming. Using a good headset isolates us from most of the noises which might otherwise distract us from attentive listening. It is much more important, however, to realize that even the rarest DX is just so much objeetionable noise to those not interested in amateur radio.

You effectively double the power of the received signal when you switch from loudspeaker listening to using a pair of earphones. When copying weak code or voice signals, use of a headset can make the difference between whether or not you can enjoy a solid contact – or even complete the contact at all!

It is important to use earphones with good earmuffs. Earmuffs keep distracting external noises out and trap the desired acoustic energy where it will be applied to the hearing system. Old earmuffs get worn and they become rigid. The rigidity is mainly due to the effects of the earmuffs repeatedly becoming soaked in perspiration. When earmuffs deteriorate, they cause a loss in the high-frequency response characteristic of the earphones. Also, some of the desired signal leaks out and undesired noise leaks in past worn and rigid earmuffs. It is important to have thick earmuffs which are very flexible. Earphone efficiency is reduced if the headband does not exert enough pressure to hold the earmuffs firmly in place over both ears. Do not use a headset which exerts too much pressure, because it will be uncomfortable. Some headsets are actually painful when they are worn more than an hour.

The more powerful earphones provide improved performance, but they are larger and heavier. The increased size is usually not objectionable but heavy headsets are uncomfortable when they are worn for a long time.

We will not all agree that the same headset provides optimum sensitivity, earmuff pressure, noise protection, weight, and comfort. If you can do so, borrow several different types of headsets from your friends and run your own comparison tests to determine which set suits you best. There are several excellent military and commercial headsets available.

As delivered, both earphones are connected in phase in a headset. When listening to an extremely weak signal buried in noise, readability can be improved about 30% by just reversing the leads attached to either earphone in your headset. The human hearing system automatically cancels noise which is presented out of phase to both ears. The preferred (out of phase) connections can be

determined by noting which connection arrangement provides the best reception of an extremely weak signal on a very noisy band. I simply installed a double-pole, double-throw rocker switch at my right earphone to permit me to change the phase of signals applied to one ear immediately; this allowed others to hear the results of the phase shift also.It is almost impossible to note any difference when listening to a strong signal or when listening to a signal on a quiet band.

If you are working a very noisy band, you can effectively mask out most of the noise by wearing a fitted pair of earplugs under your earphones. The signals will seem to filter through the earplugs remarkably well, while most of the noise will seem to disappear. If you use earplugs or transducer-type earphones, it is wise to have them fitted to your ears. An incorrect fit causes discomfort and inefficiency. The transducer-type (air column) earphones are not a good choice in any situation where several people use the same headset.

If you delay the input to one of your two earphones about 500 microseconds behind the input to your other earphone, you will realize about a 5% increase in the intelligibility of a weak signal on a noisy band.

A pair of earphones is preferable to a single earphone in a headset. Human hearing tends to cancel out noise which is presented equally to both ears. When using a dual-earphones headset, we can detect signals which are 2–3 dB lower than the signals we can hear using a single-earphone headset. Most people do not have equally good hearing in both ears. At one kHz the better ear is normally about 2 dB more sensitive and it is usually about 6 dB better at 10 kHz. Once we reach about age 25, our hearing starts to deteriorate. Our high-frequency hearing capability decreases much faster than our ability to hear low frequencies. Men usually suffer about twice as much hearing loss as women during their lifespan.

If you can apply noise out of phase to both earphones while you just apply the desired signal to one earphone, the signal will completely dominate your hearing and the noise will seem to disappear. When performing this experiment in a laboratory, the signal actually seemed to be coming from inside the head, whereas the noise sounded external and was easily ignored.

If noise is applied out of phase to both earphones – while signal is applied in phase to both earphones– signal detection capability is greatly increased. Again, this is more of a laboratory experiment than a real life arrangement.

High audio levels cause human hearing to suffer a loss called temporary threshold shift (TTS). TTS amounts to a built-in gain control which reduces the hearing level when one is subjected to loud sounds. TTS lasts from a few seconds to several hours, depending on the intensity and duration of the sound which originally caused this temporary hard of hearing condition to exist. Get in the habit of turning the gain down to the lowest point at which you can comfortably copy the signals you want. As a general rule, you will find that noise and interference are minimized by running your audio gain almost wide open and turning your radio frequency gain down to the point where you are just barely able to copy the signals you want. If you are working code, don't make the mistake of adjusting your beat frequency oscillator control to the point where you produce a pleasant low musical tone. If you're trying to listen to a signal buried in noise and other signals, it is much easier to pick out a higher pitch which is slightly objectionable.

Use a headset with an input impedance that matches the output impedance presented at the headphones jack of your receiver. Mismatched impedances cause power loss and distortion of the audio output signal. Many receivers are subject to damage of the audio output stage if they are operated without an output load such as a loudspeaker or headset. It is wise to leave a loudspeaker or a matching load resistor across the loudspeaker terminals to protect your receiver from damage which could occur when the headset plug is disconnected, or if the headset opens up.

Do not use high-fidelity earphones in your station. Headsets with wide-frequency-range characteristics just reproduce added interference which reduces communication capability. You should use communication–

type earphones with their limited-frequency -response characteristics. Effective communications can be conducted using an audio range of 400 to 400 Hz, or less. Generally the available headsets have a wider frequency response than is desired, but several come close to filling our needs.

In summary, headsets offer many advantages over loudspeakers. Nevertheless, hams frequently struggle through unsatisfactory contacts due to their use of loudspeakers. More important than the loss of communication capability is the simple fact that the use of loudspeakers makes amateur radio station operation disagreeable to other members of the ham's household. If you don't have a good headset, I am sure your family would be glad to buy one for you – providing you'll promise not to use that damned loudspeaker!

THE PERFECT CW SIGNAL

Rereading a bunch of old 73's recently, I came across an article by W3RMI on page 30 of the August, 1967 issue, "Visual Monitoring of Remote Carriers", subtitled: "What does your CW signal look like?" That set my mental gears rolling. What could a fellow do, I wondered, to get the best possible keying characteristics for his CW rig?

After thinking it over for a while, the problem resolved itself down to one question: What circuit could start and stop a sine wave (your carrier) without introducing any discontinuities (distortion) in the resulting keyed signal?

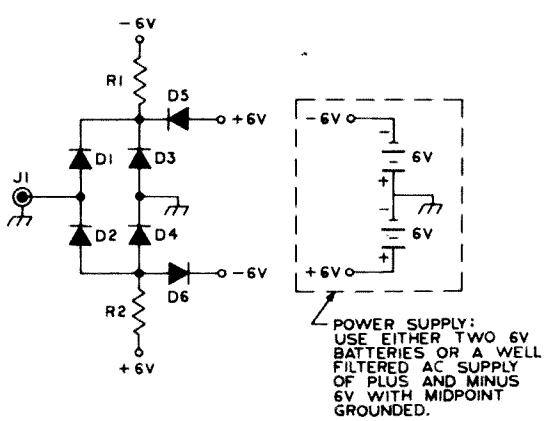

Fig. 1. A simple diode switch circuit using 6 diodes.

Suddenly the answer came – simple; the diode switch! Before I get deluged with a chorus of "Whatinhell's a diode switch?", let me explain. A diode switch is a half-dozen diodes (such as the IN4151) wired as shown in Fig. 1.

Easy, eh? Here's what happens: J1 carries the switched output. One side is already grounded and the action of the diodes causes the center terminal (the line going to the midpoint of D1 and D2) to be either open or grounded. For the open state, we apply the plus and minus 6V to D5 and D6 only. This causes diodes D1 through D4 to block both polarities of the applied voltage, causing the center terminal of J1 to stay at a very high impedance in reference to ground. In the closed state, we remove the voltages from D5 and D6 and apply them to R1 and R2. Immediately D1 through D4 conduct and effectively ground the center lead of J1 through D1 through D4 to the ground lead at the midpoint of D3 and D4. All we need now are some transistors to drive the diode switch, and a key to drive the driver transistors.

An emitter follower whose input can receive the signal from your vfo and whose output can be switched by the diode switch adds the final touch. The complete circuit is shown in Fig. 2.

Note that the circuit is set up so that the diode switch (D1 through D4) is conducting

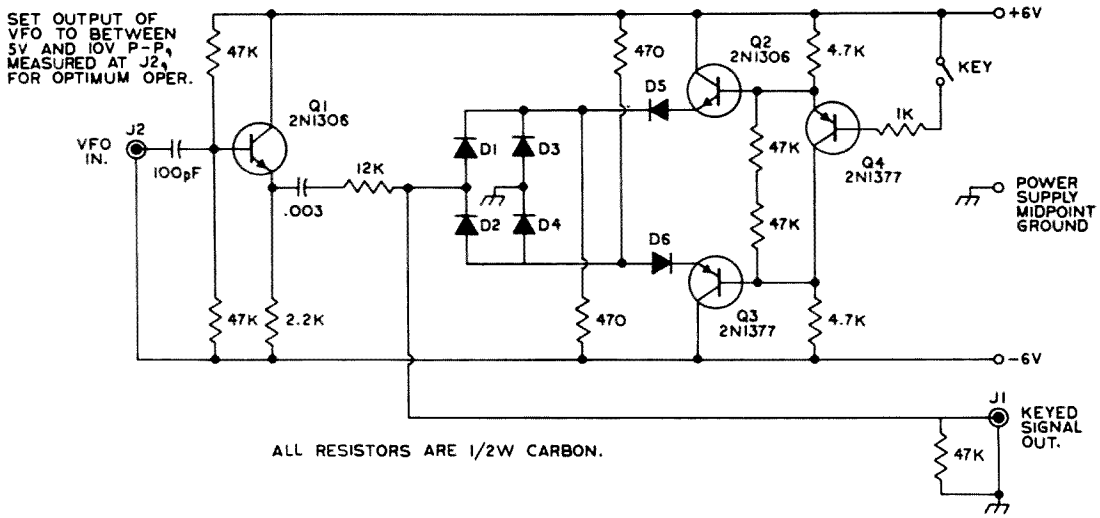

Fig. 2. The complete circuit. Note that it is set up so the diode switch (D1 through D4) is conducting with the key up.

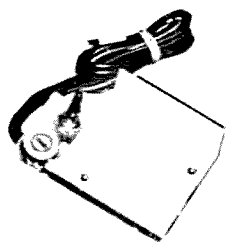
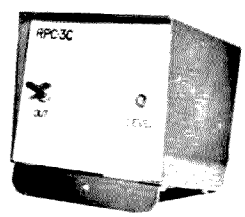


with the key up, thus turning the carrier (at J1) off. When the key is closed, the diode switch opens up, allowing the signal from the vfo (through Q1, the emitter follower isolating amplifier) to appear at J1. Since there are only 6V across the key, there is no shock hazard and the whole circuit can be wired up on a simple pegboard.

As to how fast you can key this circuit, don't bother sitting up nights building up your code speed to test its limit. This little gem will just sit back and yawn at a speed of many thousands of words a minute because the specified diodes have a recovery "speed" of 2 nanoseconds!



All you need now are power amplifiers with good linearity, and a well-regulated power supply to transmit the "perfect" CW signal.

TIPS for Raising Your Code Speed to 20 WPM

Many holders of the General or Advanced class license disavow any interest in raising their code speed to the magic rate of 20 wpm, and probably most Extra class amateurs felt the same way at some time in the past. When your code is just barely at the 13 wpm level, a speed of 20 wpm seems an impossibly difficult goal. The purpose here is to give you some practical tips on increasing your code proficiency.

Receiving and sending Morse code is purely a skill, requiring only minimal cognitive abilities. It belongs to the same class of acquired skills as learning to type, to ride a bicycle, or to ice skate. The principal ingredient needed to arrive at a certain level of performance is practice. However, the type and frequency of practice is quite important. Knowing approximately how much time will be required to increase your speed to 20 wpm can be helpful psychologically. Most of us expect faster improvement than can be reasonably expected. A realistic appreciation of the amount of practice that will be needed will help prevent the natural feeling of frustration that arises when you feel you aren't making fast enough progress. Individuals vary considerably in their learning rate for skills such as copying Morse code, but 120 to 140 hours of the right kind of practice should raise your speed from 13 wpm to 20 wpm. That amount of time may seem like a lot, but spread out over a period of time it becomes easier to contemplate. For example, if you can regularly put in 30 minutes of concentrated practice per day, five days a week for fifty weeks, your total time spent will be 125 hours. With that amount of the right kind of practice, you should be close to your goal of 20 wpm.

What is the Right Kind of Practice?

The first thought that comes to mind when you start thinking about increasing your code speed is to start having CW

contacts. Working CW will certainly help your code speed, but it isn't the fastest way to make progress for at least two reasons. First, in a QSO we generally want nearly solid copy, and as a consequence we all tend to work stations that match our own speed quite closely or even those who might be a little slower than we are. And you never increase your receiving speed unless you are pushed and made to copy material at a speed somewhat higher than your top speed for solid copy. Another reason that on-the-air QSOs tend to be inefficient as code speed improvement exercises is that their content tends to be highly repetitious. Hams unfortunately tend to say about the same things in QSO after QSO, and as a result, you can predict too easily what is coming next.

A somewhat better procedure is to spend time copying amateur or commercial stations sending at a suitable higher speed than is comfortable for you. Finding such stations is not easy, and about the time you do find an appropriate signal it will often sign off. As a result, a lot of time can be wasted tuning around looking for suitable material to copy. A better idea is to listen to one of the stations sending out code practice material on a regular schedule. The ARRL headquarters station W1AW has an extensive program of such transmissions. The detailed schedule can be found in *QST*. A number of other amateur stations across the country also feature code practice sessions at speeds in the 5 to 35 wpm range. Unfortunately, rarely more than 10 minutes is spent at any one speed. You will usually find at most two speed ranges that are really suited to your learning needs, but nonetheless these transmissions are a good source of practice material.

The Tape Recorder as a Code Instruction Device

Perhaps the best solution for obtaining suitable practice code transmissions is to prepare your own code tapes using a tape recorder. A helpful procedure is to record at half the linear tape speed, half the code speed, and half the audio frequency that you want on playback. You can use either a hand key or some form of automatic key together with an audio oscillator set at 400–500 Hz.

Can you decipher this message within 60 seconds? "Nialp hsilgne txet with all tpecxe the elttil sdrow delleps scrawkcab sekam doog ecitcarp lairetam."

Sending at half speed will enable you to record really good-sounding, accurate code characters. Plan on a playback speed 5 wpm or so above your top receiving speed. Feeling pushed during your practice sessions is quite important. To prevent memorization of the material on the tape and thus soon vitiating any practice value it would have, record plain English text with all except the little words spelled backwards. Be sure to use material containing some numbers and punctuation marks. Spelling the short, common words such as *the, an, but, for, it, on,* etc., in their normal manner is helpful because as your speed increases you will begin to recognize the short, frequent words as single-unit sounds. This type of material is better for practice than code groups because the various letters occur with the same frequency as in plain English, and you will obtain valuable experience with the important high-frequency, short-length words.

When your copy begins to get too nearly solid, prepare a new tape at a higher speed. Always keep yourself on the stretch. Before tackling that FCC Extra class examination, you should be working with a tape in the 27 to 30 wpm range, and you should be able to take almost solid copy at 22-23 wpm. You will need a margin of two or three wpm to compensate for the natural nervousness and tenseness you will feel in the FCC examination room.

How Long and Often to Practice

With a code tape available, you will be free to practice at a time to suit your own

personal convenience and as often and for as long as you wish. However, don't make any one practice session too long. Once you begin to tire, prolonging the practice period will bring diminishing returns. Probably 30 minutes is long enough for any one session. If you are really eager, one 30 minute lesson in the morning and another in the evening would not be too much per day, but most of us will find one practice period a day is about all we can or want to have.

With one 30-minute session a day, you should plan on at least a year to raise your speed from 13 wpm to a comfortable 21 to 22 wpm. If you have to miss occasional daily sessions, you ought to think in terms of 18 months. Realistic estimates of the time that will be required will reduce the frustration so often felt by aspiring Extra class candidates who have grosssly underestimated the amount of effort needed to increase their code speed merely 7 wpm.

Plateaus and Breakthroughs

A fundamental law of acquiring motor skills seems to be that progress toward a goal is never linear, but proceeds by means of a series of frustrating plateaus followed by breakthroughs to new, higher levels of performance. When you hit a plateau at 14 or 16 or 17 wpm, don't give up. Sometimes your skill may even seem to regress, but if you continue to practice regularly, you will suddenly realize one day that you can now copy at a higher speed than ever before.

Copying Behind

As your code speed increases, it becomes increasingly important to copy behind by a letter or two, or even by a whole word. Copying behind simply means that the operator does not write down the character that is being sent, but lags behind by one or more characters. Copying behind has the effect of smoothing out the rate at which code characters must be transcribed, and does away with the panicky feeling resulting from trying to write down each character before the next one is heard. As code speed increases, a certain amount of copying behind becomes almost mandatory if one is to keep from feeling too frantic, but fortunately the ability to copy behind will tend to develop more or less naturally. However, the rate at which your code speed will increase can be accelerated if you make a deliberate effort to try to copy behind. Force yourself to carry a letter or two in your head before writing them down. At first this procedure will seem difficult and unnatural, but you will soon get the hang of it.

Sending

From all that has been said so far, you might conclude that the FCC examination covers only the ability to receive Morse code, but of course you must demonstrate your ability to send at 20 wpm as well. The type of key you want to use is up to you. Since the FCC furnishes only a standard, manual key, you must bring along your own if you want to use a special type key, such as a bug or an electronic keyer. Learning to use some type of automatic key is not necessary in order to pass the code text at 20 wpm. Most individuals find a speed of 20 wpm relatively easy to reach with a standard key, but for speeds much higher, the majority of us find some type of automatic key mandatory. Generally, considerably less practice is needed to raise your sending speed than for the corresponding increase in receiving speed. In your sending practice, the emphasis should be on quality and accuracy. One easy way to monitor quality is to record periodically a few minutes of your sending with a tape recorder, and then listen critically both at normal playback speed and at half speed. You will easily be able to detect

You must feel pushed during your practice sessions for best results.

If keeping cool and calm during the exam is half the battle, guess which guy will pass?

any abnormally formed characters, and can take steps to correct them.

The FCC Examination

That fearful yet wonderful day has arrived – you are going to present yourself at the FCC district office for the examination. As a candidate for the Extra class license, you have one marked advantage over the General or Advanced class aspirant – you have been through it before. However, if you are an oldtimer, you may fear that your last visit to an FCC office was so long ago that everything is different now. I can assure you on the basis of personal experience that nothing has changed, at least not in the last twenty years. The five-minute code transmission is sent automatically be means of a punched paper tape machine, and you will be provided with a pair of black, lightweight earphones for listening. The code message to be copied is preceded by a long string of *v's*. Although the text material proper is in plain English, it contains a generous number of punctuation marks, numbers, and even an occasional Q-signal. One minute of error-free copy, i.e. 100 consecutive correct characters in the 20 wpm range, is all that is required. If you pass the receiving test, the engineer will give you a chance to demonstrate your sending ability. No precise timing of sending speed is made, but if you send markedly too slowly, you will be asked to increase your speed. Nearly all who pass the receiving test also pass the sending test. Once past the code hurdle, you are given a chance at the written part of the test, but if you should fail the code test, the engineer will politely tell you to try again in thirty days, and all that has been lost is an hour of your time, and, alas, nine dollars.

Best of luck to you. I'll be seeing you on the Extra class bands.

WHY NOT TRY QRP?

In this day of kilowatts there is relatively little low-power operation. But running QRP can be a lot of fun, even if you don't get a lot of QSO's.

When running high power all one has to do is hit the key or blow into the mike and he gets a QSO. He can talk to just about anyone he wants. But after awhile one comes to realize there is not much fun to this. One can achieve the same effect by dialing the telephone at random, and save a lot of electricity while doing it.

When one starts running QRP, hamming takes on a new challenge. No longer does one say "QRZ-599-73-QRZ" endlessly. It is *work* to get a QSO, and much more of a thrill to get it with QRP. I really got a kick out of working FP8AP on 40 CW during the afternoon with 10W, while I thought nothing at all of working ZD8OFE with 180W of SSB on 20.

Before trying real QRP, such a 1W or less, it would be a good idea to start out with *relatively* low power. Try something like 10–15W, but not much more. This power is low enough to provide some of the fun of QRP, but not so low that contacts come really hard. It is a good idea to start out with rather high powered QRP, to get used to it gradually. If one were to start out running something like ½W, he would of course have a rather large contacts-to-calls ratio and would quickly become discouraged. But by starting out rather high, and getting used to low power operation, the small number of QSO's with real QRP won't bother a person as much.

I would not recommend much over 15W to start out with. While many will disagree, I consider something like 20–30W in almost the same class as 75–100W. With 20W it is possible to get quite a lot of QSO's. I have worked 45 States on 40 CW with 25W, and many, many QSO's, and lots of others have done the same.

It is hard enough getting QSO's with a watt or so under the best of conditions, and especially when the operator has no experience running that much. I would suggest for a start you confine your experiments to

less crowded bands, like 80 meters. If you want to try 40 or higher – to get better distances – try and keep away from the more crowded parts of the bands.

Here are a few things to know before trying QRP:

1) Vfo operation is infinitely better than using crystals.

This is obvious in normal high-power operation, and much more so with QRP. What can you do if there is a kilowatt sitting on each of your crystal frequencies? And what good will a crystal for 7130 kHz do if all the activity is under 7100? You must put your signal where people will hear it right away. In these days of vfo's almost no one tunes after a CW. Even if they do tune around, they will probably hear someone else calling CQ and call them, leaving you out in the cold.

2) Wait until conditions are good.

If you hear a 559 signal tell someone he is running a kilowatt to a 100 ft high dipole, you can be pretty sure your 100 mW will be unreadable there. If someone is S 8-9 you can be reasonably sure he will hear you. But don't bother with S 6-7 signals unless you know they are also running QRP.

3) Call others, don't call CQ.

Anyone will tell you that a low power station has a better chance if he calls others. And when calling others, make sure no one else is. If you hear three 599+++ signals calling him you can be sure you will be drowned out. If you only hear weak ones calling, give it a try; you may be lucky and be the one he comes back to. Also, remember that if someone hears a 539 signal calling CQ he will assume that conditions are bad, and not bother calling.

Some will disagree on the point about calling while others are. For some, competing with QRO stations is half the fun of QRP, while others, like me, just like to get a maximum of QSO's with a minimum of trouble.

4) Don't settle for lousy antennas.

If your 100W rig does not get out well you can be certain that your 1W won't get out at all. You are already operating under a 20 dB or more handicap when running QRP, so don't make things worse by using an antenna that has loss rather than gain.

Of course, don't spend a fortune on copper and towers before trying QRP – give your existing antennas a try – you may be surprised. Read on to the examples of what has been done with QRP and look at what I did. I did it all with 10–15 ft high dipoles and a 20m vertical. (I do, however, have several logbooks full of unanswered calls, and many premature gray hairs from it.)

VE1ASJ has worked many stations on 80m CW, using 100 mW, and has worked as far West as VE5 and W6. His antenna is a three-element wire beam!!!

Some of you may have heard of the QRP Club, International. Members are limited to 100W and it has 3,000 members in 57 countries. Many of them experiment with low power. Later on are some of their accomplishments with QRPP. (QRPP is becoming the generally accepted term used for QRP Power, designating an input of 5W or less.)

The QRP Club issues several awards. One of them really has the low power operator in mind. It is the "1000 Miles per Watt" award, also called the "KM/W." It is issued for *either* transmitting *or receiving* signals from a low power station such that the great circle distance between stations divided by the power of the low power station equals or exceeds 1000 miles per watt. It is issued for work on different bands and modes. Over 150 of them have been issued. Perhaps thanks to the influence of this award, the generally accepted measure of QRP DX is "miles per watt."

This award is not really hard to win. Several people have even won it more than once. Here are some of those who have several hanging on their walls, and the bands and modes they used:

W9UZS – 40, 20, 10 CW
WA5NOM – 80, 40, 20 CW
VK3XB – 40 fone and CW, 20 fone and CW
W6TYP – 40 and 20 CW, 80, 10 2 fone*
WA8MCQ – 80, 40, 20, 15, 10 CW, plus one for receiving on 40 CW

*Current official record holder

When trying for this award, remember that the distance in miles one must work is equal to one thousand times the watts input,

or one mile per milliwatt input; eg., 2 watts need 2000 miles; 5 watts needs 5000 miles, and 250 milliwatts needs 250 miles.

The QRP Club also has another award. It is the "QRPP-WAS" Award, for working states in steps of 10, 20, 30, 40, 45, and 50. (The reason for the 45 state class is that the last five states really come hard, especially when running QRPP, so people won't get discouraged as they approach 50.) For this award, the maximum power that may be used is 5W, and there is an endorsement for using under 1W.

Here are a few of the things being done with QRPP:

WA8MCQ: I have worked 47 states with 800 mW and under. Anyone in KH6, Oregon or New Mexico want to sked me? I have the KM/W six times, and have qualified many others for it by running low power. Have over 300 contacts with under 1W, and often run the 80 mW rig in contests, and make at least 20 contacts, and made 73 once. I usually establish contact with the small rig, but a few times I use the big rig first, and ask people to listen for my QRPP, in order to get a few of the harder states.

WA5BMN: Used to keep regular skeds with W6TYP, running under ½W both ways.

WB2YPA: Running 3 mW he worked WA6ZHP, a QSO good for 800,000 miles per watt. This fantastic feat is close to the official record, which is held by W6TYP.

WA8RQQ: Worked several VK's with 10W and less, plus much more DX, including 11 countries with under 5W. Of course he has the KM/W. He even worked an HK3 on 40 CW at *noon* with 1W, and got a report of *599*!!

W8AVB: Has a 200 mW vfo rig for 80 meters, with which he worked at least 30 states, including some 6's and 7's,

W7IGV: Had been keeping regular skeds with W6EAC on 40 CW, both using 1 to 2 watts. One day W7IGV showed up on sked "maritime mobile" from a rowboat on Lake Coeur d'Alene in Idaho! W6EAC could hear him but could not copy. The effort was not wasted, however, as WA7BIY, running 5W, W7OE and WA7FYW, all in Washington, broke in, and solid copy all around. W7IGV's antenna was 10 ft of loaded whip. (From Sept. 1968 issue of *Random Radiation* official organ of the Pacific Amateur Radio Guild, published by W7OE.)

WA9MFZ: Running 2W he worked a station in Colorado who was running 800W, and got a report of only 2 S-units lower – pretty good for a 26 dB power difference!

W6TYP: Art has worked at least 24 states with under ½W, plus 4 countries including ZL. He is the current official record holder for miles per watt. He worked WA6JPR on 40 CW to set the record. He was running 354 *microwatts*, and the other guy was 354 miles away, a QSO good for one million miles per watt.

W2UUV: According to a letter in the October 1964 issue of *QST*, on page 104, he is the unofficcial record holder for miles per watt. He worked W2BNA, 205 miles away, while running 67 *microwatts*, a contact good for over *three million miles per watt!!* This guy has got to be one of the top QRPPers around, as far as miles per watts go. He logged 15 successful attempts out of 15 to make over 105,000 miles per watt, working with W2BNA, a 205 mile path with a milliwatt and less. He says that W2BNA is tops, and often runs up scores of over 600,000 miles per watt. He also says that K1HNJ made 769,000 miles per watt, at 100 miles and 130 microwatts. He says he has 31 states plus KZ5 and DJ, all on 80 meter with 180 mW. Sometimes he runs his final off a solar-battery which he puts in the window, and others get quite a kick out of it. He also sponsored a "QRPP QSO Party" a couple of years ago, in which the maximum input allowed was 300 mW.

The foregoing should inspire some of you QRO people to give QRP a try. It's lots of fun, and beats running a KW anytime. (Note; I meant it's more fun than running a KW, *not* that it will do better than a KW!)

Anyone interested in joining the QRP Club can obtain information and application blank by sending a self-addressed stamped envelope to K3YNN, the Corresponding Secretary of the Club. Lifetime dues for the club are only $2.

Whenever you are on the air, give a listen for some of those real weak signals you hear, and you may make some. QRPPer very happy.

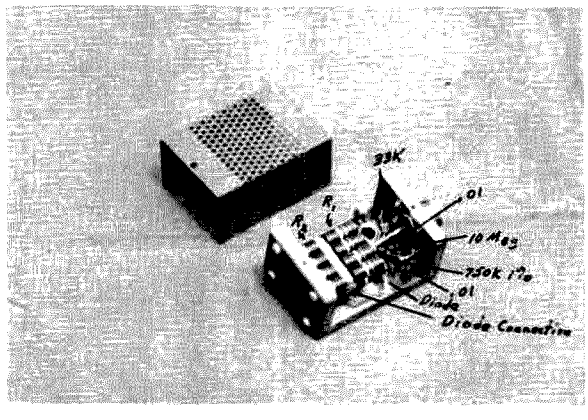
VHF DUMMY LOAD WATTMETER

The active vhf amateur often has need of some type of dummy load for transmitter checkouts. The units found in amateur applications range from the Bird "Termaline" units costing around $350, downward through the Waters units, through the Heathkit Cantenna, to the inexpensive units described in the various amateur publications.[1] The Bird and Waters units have the advantage of a direct readout wattmeter movement, whereas the cheaper units are dummy loads only. A dummy load serves as a constant impedance load while keeping the signal from interferring with other amateurs. When a wattmeter or relative output meter is added, the dummy load becomes a very useful piece of equipment.



The unit

The unit described herein is similar to some 60 watt units which may be found around many commercial two-way radio shops. This dummy load has provision for connection to an external relative output meter. This external output meter may become an accurate wattmeter if the following criteria are met:

1. Frequency bandwidth of $\pm$10% of calibration frequency.
2. RF output kept within power dissipation of dummy load.
3. Accurate initial calibration.

These criteria may be easily met in amateur vhf operation if only one band is considered for each set of calibration data. Since most vhf amateurs operate on 50 mhz, 144 mhz or 432 mhz, the $\pm$ 10% frequency limitations may be easily met. This limitation gives a 10 mhz bandwidth at 50 mhz, 29 mhz bandwidth at 144 mhz, and 86 mhz at 432 mhz. The limitation to the power ratings of the dummy load is only common sense, for if a resistive network is overloaded, the impedance may be drastically increased, caused by damage to the load resistors. The calibration limitation may be overcome if a standard, previously calibrated unit, or commercial unit is used.

The unit may be built for less than six dollars (less meter movement) if all new parts are purchased from Allied Radio, or at much less if a little scrounging takes place. The unit consists basically of 16 220 ohm resistors in a series parallel arrangement. The metering circuit consists of a germanium diode pickup with necessary *rf* filtering. The meter movement is generally a vom, but any 50 μa meter movement should suffice. Exact physical

Parts layout and interior view of Dummy Load – Wattmeter

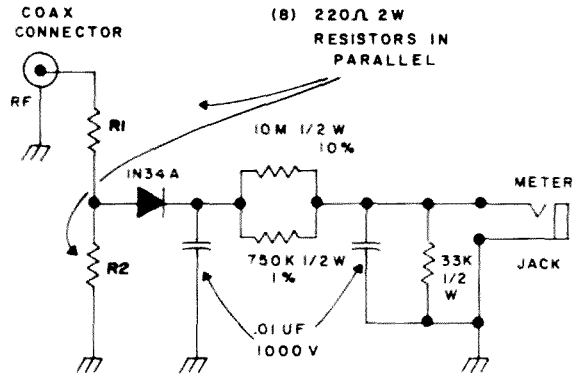


Fig. 1. Schematic. R1 and R2 consist of eight resistors each, in parallel.

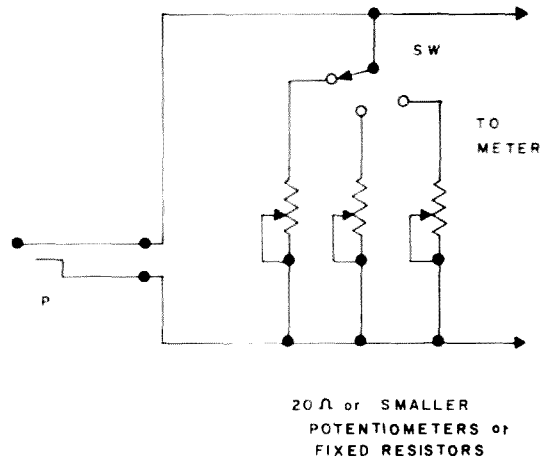

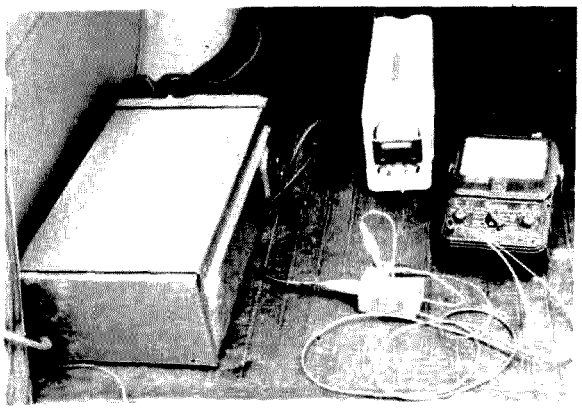

Fig. 2. Metering shunts.

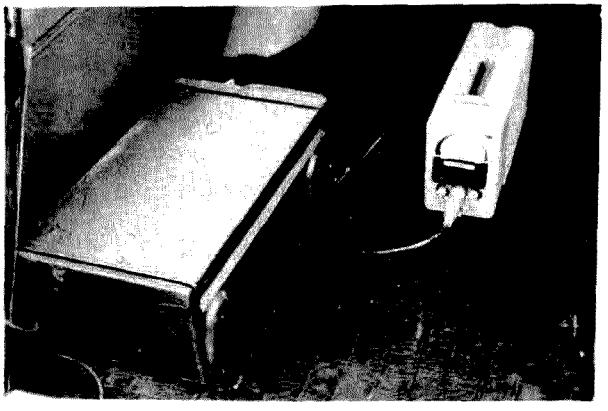

layout is not extremely critical, but it is suggested that the layout be made similar to the unit shown in the accompanying photographs. This unit is acceptable for 60 watt output transmitters without modification. The power capability may be increased to about 200 watts if the resistive network is suspended in 1 quart of oil. If this is done, care must be taken to keep the metering circuit out of the oil. The lead from the diode to the resistive network must, of course, be partly submerged, but keep the diode itself out of the oil. I do not personally use this arrangement, but I know of two units which have been in use at a large Southeastern two-way radio shop for several years. The same shop has incorporated a range switch with several meter shunts for various maximum scale power readings. This feature is especially useful to the amateur vhf fm operator who may be working with equipment of from ½ to 250 watt outputs. The schematic appears as **Fig. 1**, and the basic circuit for various meter shunts as **Fig. 2**.

Calibration

Calibration is best accomplished by using a Bird "Thruline" or similar commercial vhf inline wattmeter. Second choice is a Bird "Termaline" or similar dummy load-wattmeter. In both cases, a graph should be created by plotting meter divisions on the horizontal axis, and power on the vertical axis. The meter shunt should be placed at minimum resistance and increased to give maximum reading at the desired power level (this holds primarily true for units using the metering circuit of **Fig. 2**) or, if a vom or vtvm is being used the range switch should be placed on a high voltage setting and reduced a setting at a time until the desired reading is obtained. The transmitter should be adjusted for various power levels on the standard wattmeter and the voltage or current reading on the new meter recorded on the graph. In the case where the standard meter is of the dummy load-wattmeter type, it will be necessary to switch the coax from one unit to the other. Do not retune the transmitter, for each unit will present almost the same load to the transmitter (50 ohms). Take the reading and record as with an inline type of meter. The points on the graph should now be connected with a smooth curve (use of a draftsman's

FM YOUR GONSET COMMUNICATOR

- New! Plug-in modulator puts the Communicator transmitter on FM.
- No modification or rewiring of your Communicator. Just plug into mike jack and crystal socket.
- Compact self-contained modulator measures 4" x 3" x 1½".
- Works with Communicator I, II, III, and IV.
- FM at a tenth the cost of a new rig.
- Frequency adjust for netting built in.
- Built-in tone burst available. Keyed by push-to-talk switch.
- $34.50 postpaid U.S.A. Built-in tone burst $10.00. Specify Communicator model and tone-burst frequency. 5% tax in California. (HC-17/U crystal and 9 volt transistor battery not supplied.)
- Send for free descriptive brochure.

range switch is used, it will be necessary to calibrate for each switch position. Also, if multi-band use is expected, the graphs must be made for each band. Use of the wattmeter now requires only the connection to the transmitter, setting of range switch to the proper level, and reading the graph.

Uses

The uses of this dummy load-wattmeter are as varied as the amateur mind can devise. One very important use is determining the losses of 50 ohm coax. Measure the output of the transmitter at the transmitter. Then measure the output at the end of the length of coax. The losses in the line become apparent. The loss in db may be calculated by the standard power ratio formula, 10 $\log_{10}$ Power out of coax/Power into coax.

Another use is the determination of efficiency of final amplifier stages. This efficiency may be calculated by Power out (measured by dummy load-wattmeter)/Power in (measured by plate current/plate voltage meter) x 100%. A third use is determining once and for all which amateur really has the most output. This list may be expanded by the builder to suit his own tastes.

Conclusion

This dummy load-wattmeter is not a Bird "Termaline" nor should it be regarded as a substitute for any other laboratory equipment. However, with a little care in calibration, (assuming a 5% accuracy standard is used for initial calibration) the accuracy should be within 10%, and this, my friend, is not bad for a wattmeter costing less than $10.

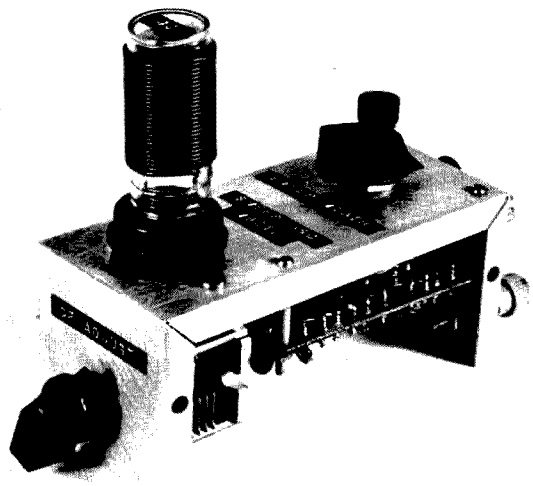
An Experimental Sweep Oscillator



This article describes a sweep frequency oscillator that was put together to gain some experience before tackling a more sophisticated instrument to be used in a specific application. The unit described is relatively simple and can be used to sweep a signal across all or any portion of the ham bands below ten meters.

The heart of this device is a special diode called a varicap. All diodes exhibit some capacitance across their terminals when they are reverse biased; i. e. when a positive dc potential is applied to the anode with the cathode returned to the negative side of the supply. Varicaps are fabricated by special processes to make their capacitance in the reverse biased condition vary in proportion to the amount of bias voltage applied. A plot of the capacity variation with voltage is shown in **Fig. 1**. While the curve is not linear, it can be seen that from about 2 volts on up it does not vary too much from a straight line. Also, not much capacity change occurs above 5 volts bias, so the range from about 2 to 5 volts is the most useful part of the curve.

The curve in **Fig. 1** is normalized to unity capacity at 4 volts bias because nominal varicap capacities are specified at this bias level. To use the curve, the nominal value of the diode to be used is multiplied by the factor on the vertical scale at the bias applied to determine the capacity at that bias level. For example, the varicap used in this sweep oscillator has a nominal value of 12pF. If the bias voltage were 2 volts, the multiplying factor from the curve is about 1.4, so the capacity at 2 volts bias is 1.4 x 12 or 16.8pF. At 6 volts bias the factor is about 0.82 and the capacity at this voltage is 0.82 x 12 or just a little under 10pF.

Before beginning this project, some theoretical plots were made to see how a sweep oscillator with a varicap in the tuned circuit should function in terms of sweep widths with diodes of different increasing nominal values. These curves are shown in **Fig. 2**. The 80 meter band was selected for the calculations with 12, 33, 47, and 68pF diodes in the tuned circuit of the oscillator. The curves were set up so that the oscillator is on the same frequency at 4 volts bias no matter which diode is in the circuit. The total tuning capacity at this point was assumed to be 100pF. As the curves show, the entire 80 meter band could be covered with a 47pF varicap with reasonably good linearity. By limiting the voltage variation with the 47 and 68pF diodes, any portion of the band could be covered. On the basis of these curves at 3.5 MHz, the higher bands, where less capacity change is required for a given frequency shift, should present no problem.

To make an elementary sweep oscillator it is then necessary to provide the frequency determining circuit of the oscillator with a varicap as part of the capacitive element and

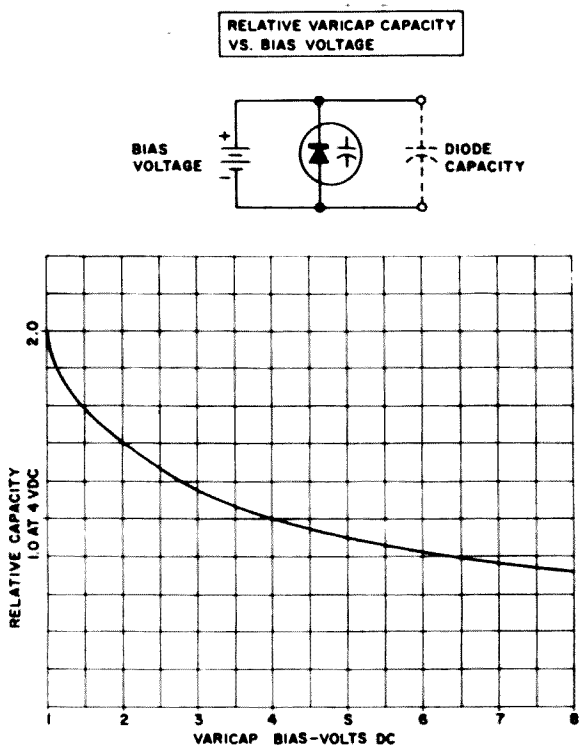


Fig. 1.

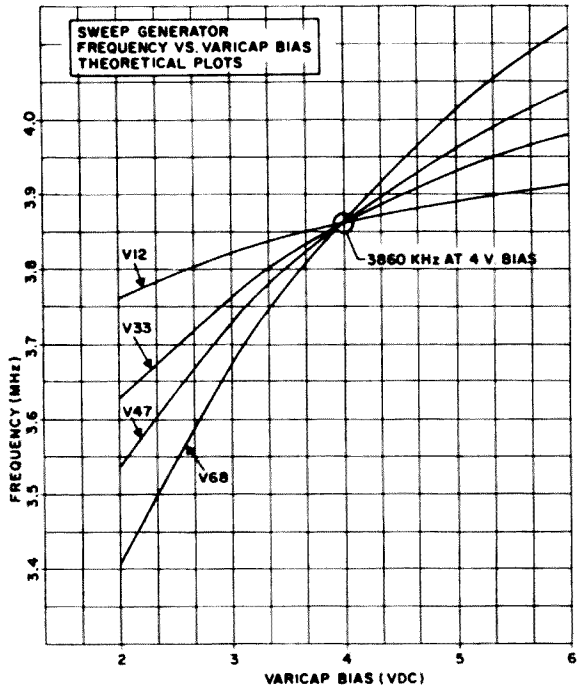

Fig. 2.

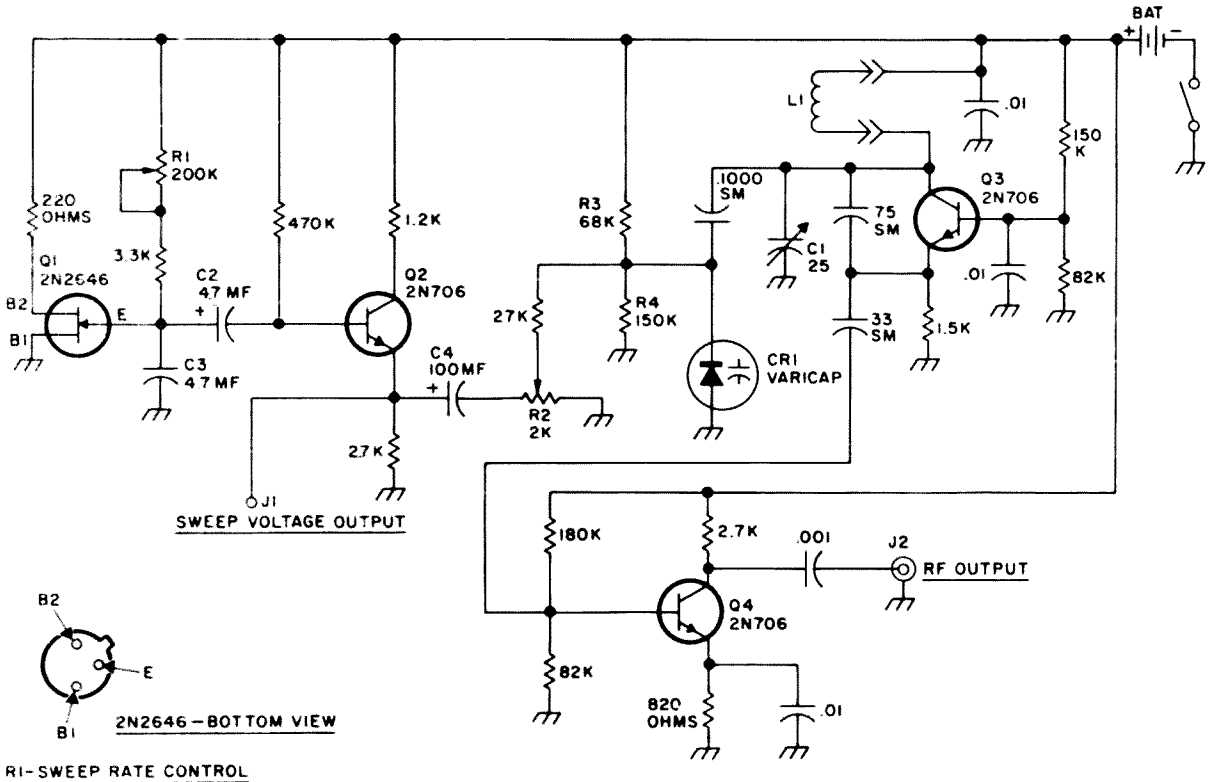
find some way to vary the dc potential across the varicap repetitively. The schematic diagram is shown in Fig. 3.



Q1 is a unijunction transistor relaxation oscillator that generates a sawtooth waveform. This sawtooth is used to provide the voltage variation across the varicap to provide the sweep function. The potentiometer R1 sets the sweep speed and can adjust the sweep rate from under one sweep per second up to about 50 sweeps per second. The sawtooth from the unijunction is coupled into Q2 which feeds the varying dc voltage to the varicap. Q2 also provides a sweep output that can be applied to an oscilloscope as will be described later. Potentiometer R2 adjusts the amount of voltage variation applied across the varicap which controls the amount of frequency shift or sweep width.

The oscillator section is straightforward. The 25pF air variable capacitor C1 is used to set the center frequency around which the oscillator is to be swept. The frequency set capacitor is kept at a small value so that the relatively small variations in varicap capacity have a sufficient effect on the frequency and thus the sweep width. At the higher frequencies not much capacity variation is required, and the width of sweep can be adjusted by R2 if it becomes too great.

Q4 is used as a straight amplifier to boost the output signal to a usable level and to provide isolation between the oscillator and whatever load might be applied. The unit described provided about 2.5 volts rms on the 40 meter band and about a volt rms on 20 into a high impedance load.

The unit shown in the photograph was built in a 2¼ x 2¼ x 5" Minibox. As was mentioned earlier, this project started out as an experiment and a larger enclosure might have been better since the parts became rather crowded after several additions and modifications were made. The center frequency adjust capacitor C1 is mounted on the front apron of the box with an octal socket for the plug in coils mounted immediately above it on top. The sweep width potentiometer R2 is mounted on top toward the rear. On the rear apron are the sweep rate control R1, a BNC *rf* output connector and a universal binding post for the external sweep output connection. Originally it was planned to use a fixed sweep rate, but when a variable rate was found to be useful the rate control took the spot that was intended for an on-off switch for an internal battery. As a result, two binding posts were mounted for connection to an external battery or power supply.

The circuit is wired up in typical transistor construction fashion on a phenolic board. The unijunction circuitry is toward the rear and the oscillator/output amplifier

toward the front near the center frequency capacitor. The board is supported on 1" pacers from the top of the minibox.

The plug-in coils are wound on plastic coil forms (I used pill bottles) 7/8 inch in diameter. Winding data is given in the table. After the turns have been adjusted to cover the desired range the forms are cemented to octal plugs. The only coils wound for this experimental version were for the 40 and 20 meter bands.

Amateur bands were chosen for ease in checking sweep widths with the bandspread scales on a receiver. When the oscillator is functioning it can be heard sweeping across the band in use. By tuning across the band, the upper and lower limits of the sweep range can be found when the thumps as the oscillator goes by can no longer be heard. With the circuit shown it was possible to sweep all but about 30 kHz of the 40 meter band, and on 20 meters the sweep width was a little over 400 kHz, covering more than the whole band. Minimum sweep width on both 20 and 40 was between 10 and 20 kHz. No attempt was made to calibrate the center frequency capacitor because this can be found by the receiver calibration. Also, the center frequency depends somewhat on the sweep setting, as is explained later.

Applications for this device will probably suggest themselves to anyone interested in trying such a gadget. Of course it can be used in conjunction with an oscilloscope to get a visual display of the frequency response of the tuned circuits in an *rf* amplifier by connecting the external sweep output to the horizontal input of the scope and the amplifier output to the vertical channel. Also, by just using the external sweep

connected to the horizontal input, sweep speeds lower than provided by the usual garden variety scope can be obtained.

In conclusion, a few comments on the circuit might be in order. No provision was made for turning off the sweep; but by turning the sweep rate control to its maximum resistance position, the unijunction stops and thus the sweep. I found that the signal, with the sweep stooped, sounded rather coarse in the receiver; but this is probably due to noise, etc., being picked up by the varicap.

The varicap used is a V12E manufactured by Pacific Semiconductors. This series is available values from 7pF to 100pF so wider sweep ranges could easily be achieved. They are available from Allied Radio for about $3.00.

As was mentioned before, an external power source was used. Supply voltages from 12 to 18 volts are about right, but it should be pointed out that the resistors R3 and R4 must be adjusted to suit the supply voltage used. These resistors (along with R2 and the 27K resistor feeding the sawtooth to the varicap) form a voltage divider which sets the static bias on the varicap. To set this up, set the sweep rate at a low speed and connect a vtvm across the varicap. As the voltage divider R3 and R4 is adjusted the vtvm will swing back and forth slowly with the sweep. The divider should be adjusted so the meter swings around approximately 3.5v as a center point. Since the sweep width control R2 is in parallel with R4 through the 27K resistor, changing the sweep width will also change the center frequency slightly because the static bias level on the varicap will be changed.

The curves of Fig. 2, while being theoretically sound, cannot be duplicated on 80 meters with the circuit shown because the voltage shift across the varicap is not enough to produce the shifts shown.

Although this generator is rather simple, it proved to be a very interesting project and much was learned. The general circuit shown, with varicaps of larger value and suitable coils, should be capable of providing any desired shift at any frequency. An obvious application would be to build this sort of device to tune 455 kHz (or other if frequencies) for receiver alignment purposes. A different oscillator circuit would be required and plans are under way to try this in the future.

WHO CAN'T LEARN THE CODE?

R. B. Kuehn W0HKF
1212 Bellows St.
St. Paul MN 55118

I'd give anything to get an amateur license, but I'm one of those people who just can't learn the code." It seems there are more of these unfortunates each year swirling around the fringes of ham radio. Let me tell you how this supposed inability to absorb an elementary skill all began.

Many years ago there was no such thing as a person who couldn't learn the code. With equal enthusiasm young Johnny Ham tackled learning the code and how to build and operate his station. The required code speed in those days was only 10 words per minute for the General Class license, but then the only reason the FCC has since raised it to 13 wpm, I understand, was in response to the widespread conviction that the present generation has at least 30% more on the ball than the preceding one.

Then along came WWII with its urgent demand for far more military CW operators than amateurs could possibly supply. The armed forces set up radio schools and one of the entrance requirements was to pass a "code aptitude" test. Fellows with recent exposure to military methods can vouchsafe that even today the armed forces are not notably successful in placing men in the areas of their greatest talent and interest.

Imagine then how it was 30 years ago in the hurry and confusion of an approaching war. Great numbers of would-be radio operators were told they had no code aptitude and were summarily sent off to become cooks or hospital orderlies – for which they probably had no aptitude either.

With war's end and the resumption of amateur radio it didn't take long for the miliary radio school dropouts to spread the idea that many people lack the wits to learn the code. Nonsense.

Anyone who has learned that when he hears the three syllables 'dou-ble-you" pronounced it represents the letter W can also learn that three other syllables, "dit-dah-dah" represent the same letter in Morse code. If one letter can be learned so can the others – it's that easy. Building up speed is then a simple matter of repetition just as in any other subconscious skill, like tying your shoes, for instance.

Is there a valid argument to the contrary? If there is, I've never heard it!

The Greater Dipper

Introduction

To the uninitiated, a grid dip oscillator is neither glamorous nor exotic, even if it does happen to be transistorized. But to those who have ever tried to put a coil on frequency, one is worth its weight in microcircuits.

The original model of the *Great Dipper* proved to be a versatile, if unexciting, grid dip oscillator. Intended to be used mostly at VHF, the dipper was limited to frequencies above 28 MHz. To those who seldom operate above 10 meters, the lack of frequency coverage below 28 MHz was a definite handicap. Expanding the frequency coverage downward extends the dipper's usefulness considerably.

Component changes made were not extensive, nor were the physical dimensions of the unit changed. The schematic diagram of the modified circuit is shown in Fig. 1, and the pictorial diagram of Fig. 2 is included to supplement the photographs printed in the original article.

Modification

First, the oscillator circuit board should be rotated 90 degrees from its original position so that transistor substitution or replacement can be made easily. A microwave diode might be substituted for the original glass computer-type diode; this results in better performance at VHF, but its effect cannot be accurately predicted. A 1N21 or 1N23 diode could be used in place of the D4900 called for in the schematic. Best oscillator performance over a wide frequency range results from using a 5 pF capacitor as the collector feedback coupler, but this was a compromise value. If operation is likely to be confined to either the HF or VHF segments of the radio spectrum, some experimentation with this capacitor should result in improved performance over that particular range. For experimentation, use a 3-12 pF or 4-30 pF trimmer.

To perk up meter amplifier performance, replace the 2N918, a relatively high gain, low leakage transistor. Meter amplifiers are not difficult to construct, and more information on them can be obtained from articles published in 73 Magazine.[2,3]

Although the change was not made in this unit, a 6-100 pF (MAPC-100) variable capacitor could be substituted for the existing 5-50 pF unit. As can be seen from the full-size scales, frequency coverage is narrow on the 13-23 MHz plug-in coil. Those who

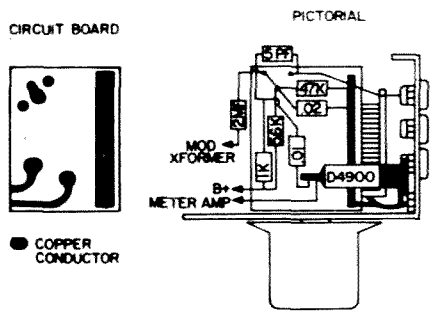

Fig. 2. Pictorial view of the dipper and its circuit board.

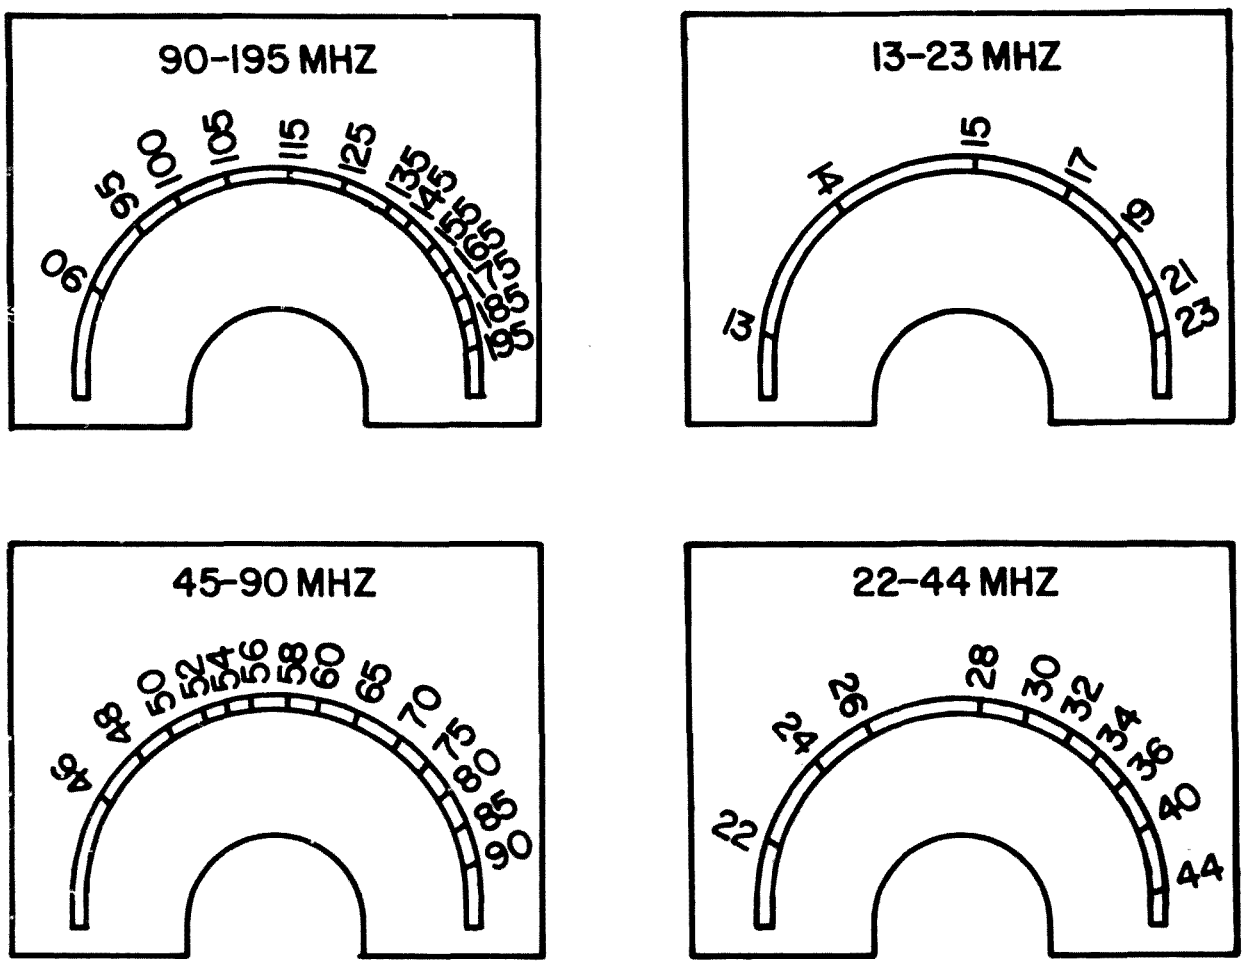

Fig. 3. Dial designs for the various MHz ranges, full size.

frequently construct HF gear might benefit from the substitution.

Operation

Operation of the dipper is the same as before, except the frequency range is greater. Another coil must be wound for the 10-25 MHz range, but existing coils were not modified. Calibration is now different from before; full-size scales are included with this article for those who do not have a general-coverage receiver or another grid dip oscillator on hand for calibration.

Oscillation is still vigorous at 13 MHz, which indicates lower frequencies may be reached with a suitable coil plugged in. Similarly, oscillation is still noticeable at 195 MHz, so operation at higher frequencies may be possible.

Finishing Touches

Appearance of the dipper was improved after enlisting the help of a draftsman. The dial and meter scales were professionally inked. **Figure 3** provides full-size copies of these scales.

To improve the legibility of the labels and scales, they were inked on yellow cards rather than on conventional white paper. It's a small point, but for those who use test equipment frequently, the black-on-yellow technique results in less eye strain.

Pull the plug on the rig; in its stead, plug in your trusty (rusty) soldering iron and get started on this small project.

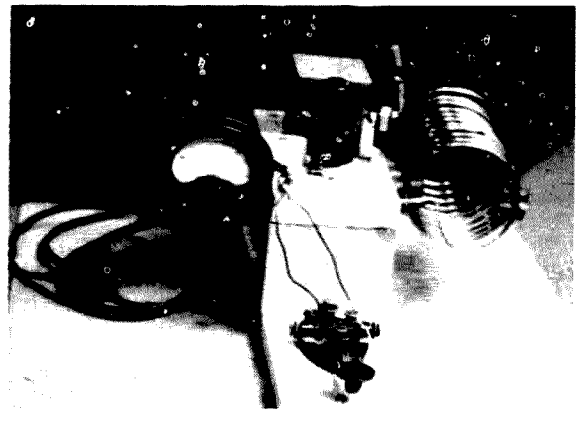
CQ DX on ½ WATT

If someone had told me that one day I would be getting out on the air *too* well I would have administered a well-placed kick and gone back to grumbling about TVI, ignition noise, tower restrictions, and the like. Well, here I was on an isolated Coast Guard station far from TV and motor vehicles. I had a full kilowatt and a tower topped with a three-element beam. And I was bored.

In the first six months on the island I had worked DX as I had never done before. I operated USB, LSB, DSB, and NO SB (CW) – and the DX poured right in. Before long, however, the novelty began to wear mighty thin and, since I am not a certificate collector, I began to cast around for something new.



The idea of QRP operation ("low power," if you're not in the know) came by accident as I listened around the band one night. There at the low end of 20 was a UA9 calling CQ. Deftly, I zeroed in on him and keyed back the usual short, confident reply. As I rapped out *KN*, I realized that in my haste I had neglected to flip the plate switch on the Thunderclap XVII. Without the big rig, I was naked – a defenseless victim for QRN, QRM, and QSB. I would never get through. But what was this? An answer!

My hand shook on the key: "Rig is running 100 watts," I said.

"FB Sig," he said.

I had done it. I had broken through the power barrier. Not going up this time, but coming down. Would it be possible, I mused, to get out with (shudder) *10* watts?

The following day I called a ham in town and asked him for the loan of his old Novice rig. He was very obliging and the rig floated out to me on the next supply boat.

A 6AG7 in working condition for the tube and a clean board for the chassis.

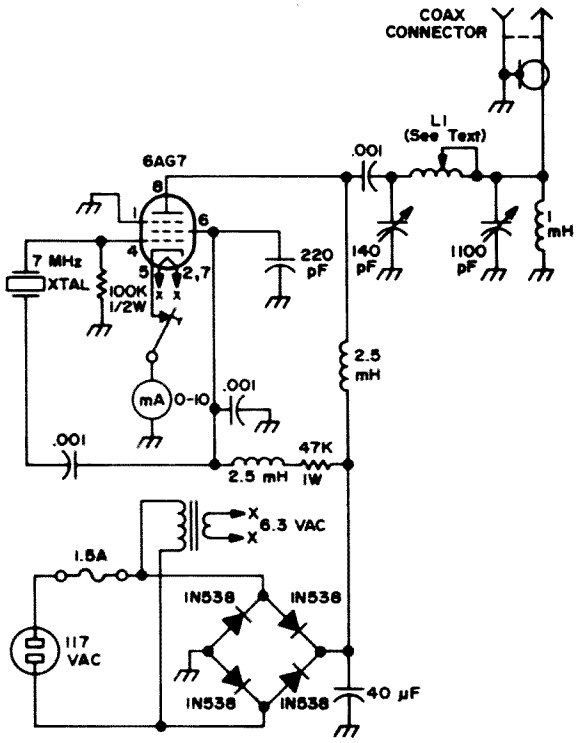


Fig. 1. This "monster" really works. 1.2W input but lots of contacts. This is real QRP.

I set it up and measured the input. Eleven watts – almost. It was close enough! And it was crystal controlled! I put it on the air, and within a week I had accounted for 14 states and 3 countries. What next?

The inspiration took me by surprise. One moment I was moping over the Novice rig and the next I was digging busily through the junkbox, pulling out likely looking components for a rig to end all rigs (and maybe all QSOs too).

Could I, I mused, build a rig using one receiver tube and junk parts of the TV variety? Could I nail them all to an old board and still make a contact? Could I?

Well, a 6AG7 in working condition was the tube, and a clean old board the chassis. I could not find a transformer anywhere, so line voltage would have to do. I did find a filament transformer after a mighty search. I was really sweating the vision of a big bank of resistors or a long string of do-nothing tubes to drop the line to 6.3V.

All went well and Fig. 1 shows the result of my labors in low-class circuit design. Some of the component values I figured out by use of formula but, as many have found, it just doesn't want to work that way. So I was forced to resort to put-it-in-and-try-it techniques. If you have a grid dip meter around you've got half of it licked right there.

The rig is a funny sort of Pierce oscillator and amplifier all in one metal-cased tube. I put in a pi network to match the 50Ω transmission line impedance. The key and meter are in the cathode lead (she'll chirp like a bird, I thought).

The tank coil is a wonder. You can't help but wonder why it is so big. Why would anyone in his right mind want to put a 500W coil in a 500 mW rig? Well, it seems that in the junk heap I came across this nice shining 12-gage wire; and since I didn't have any small coil forms anyway, what the heck! I spaced its 11 turns with hunks of rubber so that I came out with about three turns to the inch and a length of about 4 in. I rolled it on a partly empty roll of Teletype paper so the diameter just happened to come out to 3½ in. I drilled holes in the side of my wooden chassis and hammered the ends of this little beauty into them so it is mounted nicely on the side of the rig. An alligator clip provides for tuning but as it turned out, the coil works best without any of it shorted.

This monster really works. The tube runs at 150V and 8 mA when dipped (10 mA not dipped). This figures out to about 1.2W input and, considering the efficient design, I would imagine about 500 mW or below ever sees its way to the antenna. It is barely enough to move the pointer on my swr bridge more than half an increment – and you have to look closely to see it move!

When the plate is dipped carefully there is no chirp, and the rig puts out a fairly clean signal. Because I am keying the oscillator, I always monitor with the receiver to make sure there is no chirp or frequency drift.

After a week of operation on 40m with a dipole 10 ft up, the rig turned in great reports from everywhere. So what next? I wonder how a souped-up version of the 2N107 would work out?

20-60w 1-4 BAND TX

It is indeed easy to build a transmitter which will run 20–60W on 7, 14, 21, or 28 MHz with excellent efficiency. Figure 1 is the circuit, and this is so well proved that it would be difficult to find any snags; and the constructional work could scarcely daunt anyone. Probably few other circuits can give so much with so little complication. You can even connect a modulator if you like – either for screen grid, or both plate and screen (high-level) voice working.

The 5673 is a crystal oscillator able to provide output on the crystal frequency, or multiples of this. As an example, a 7 MHz crystal will allow working on 7, 14, and 21. This type of oscillator is astonishingly easy to get going.

L1 is the plate coil, tuned by C1. L1 is for the band on which output is required from the transmitter, so that the power amplifier works straight through on all frequencies. The final is a 6146, and running up to 100 mA at 600V (60W input), it is well within its ratings. As a 6146 can easily cook itself with its own juice off-tune or without bias, and bias is obtained by grid current through R3, a 5

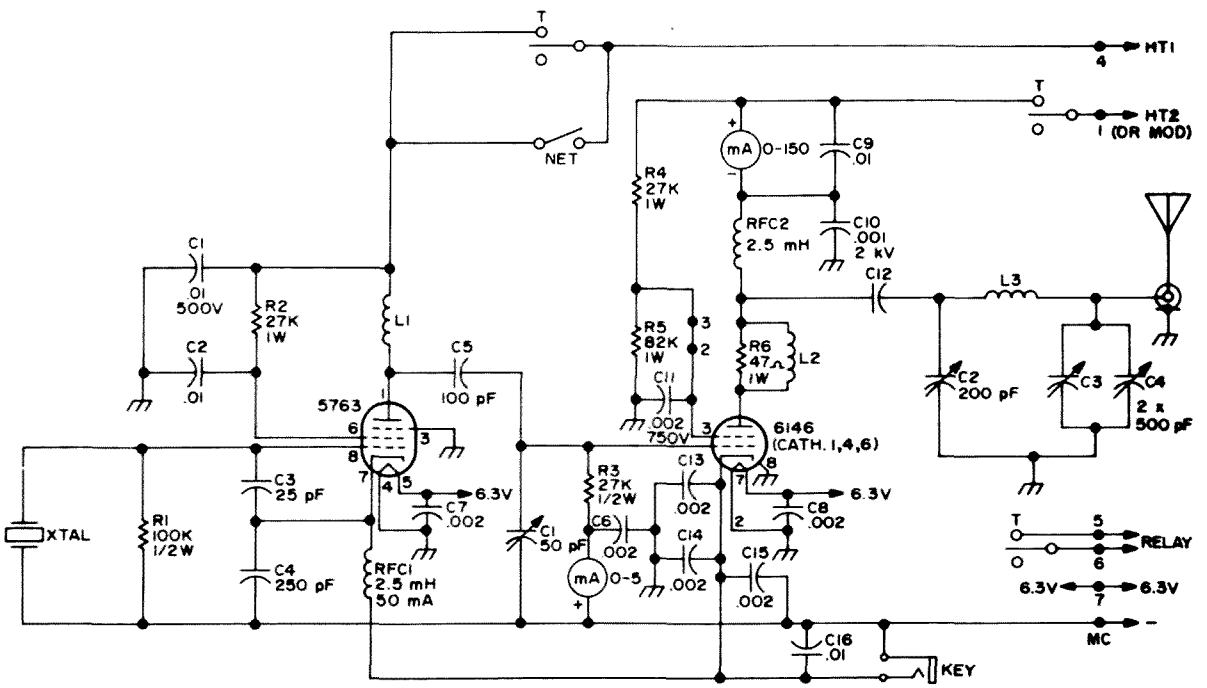

TABLE I–DATA				
BAND	DIAMETER	NO. OF TURNS	GAUGE	LENGTH
7–L1	1/2 in.	40	24	—
L3	1-1/4 in.	22	18	2 in.
14–L1	1/2 in.	20	24	—
L3	1-3/4 in.	10	16	1-1/8 in.
21–L1	1/2 in.	9	22	—
L3	1 in.	11	16	1-1/4 in.
28–L1	1/2 in.	9	22	—
L3	1-1/4 in.	5	14	1 in.
NOTE – L1 ALWAYS HAS TURNS SIDE BY SIDE				

Fig. 1. Circuit of 1–4 band transmitter.

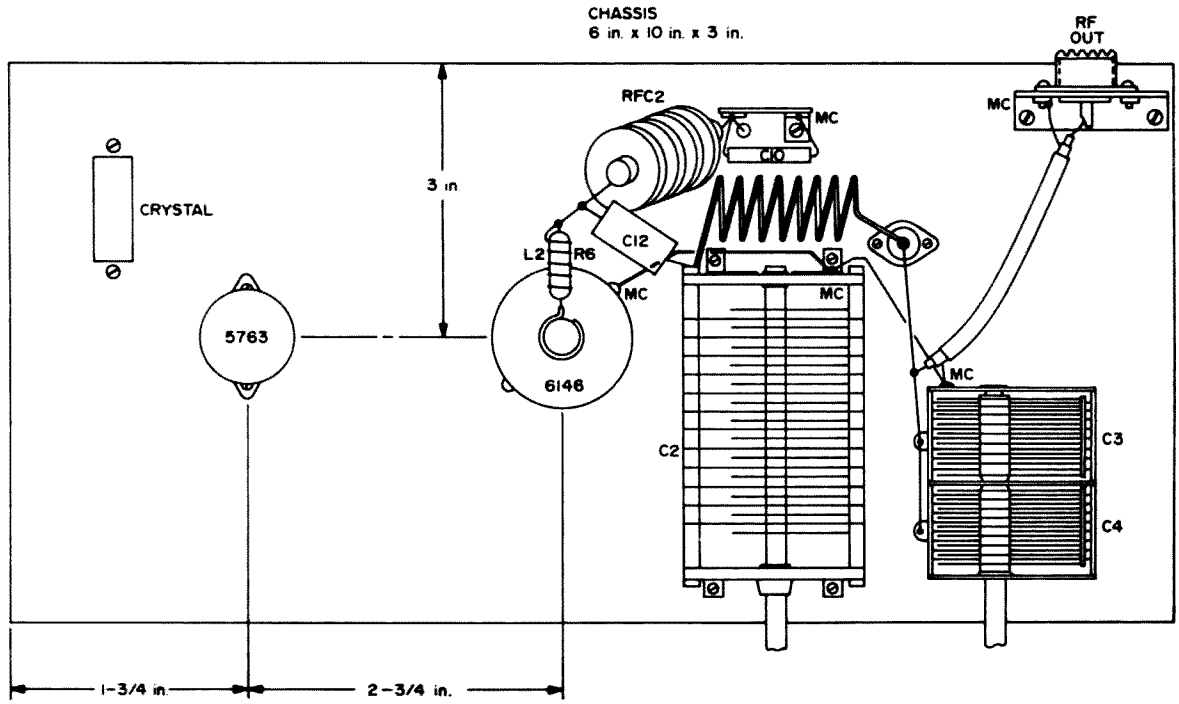

Fig. 2. On top of the chassis.

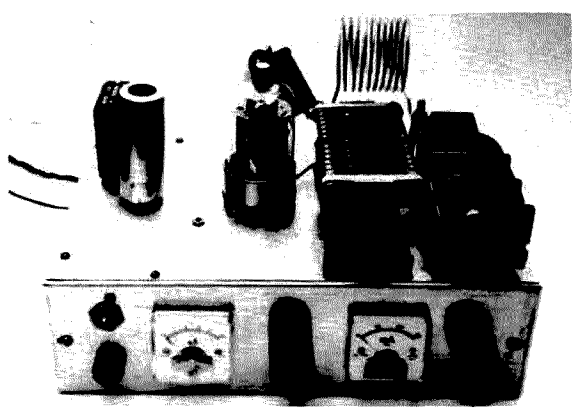
mA meter monitors grid current. So on any band, you simply tune C1 for about 2 mA grid current, giving about 54–65V grid bias.

After the parasitic suppressor (L2/R6), rf reaches the pi tank L3, with power amplifier tuning capacitor C2, and output capacitor CE–4. This will match into a dipole and useful range of other impedances.

Keying is via both cathodes, giving complete cutoff with the key up. R5 and R7 are to keep screen-grid and cathode voltages within limits with the key up. With the key unplugged, the key jack closes, for tuneup of grid current or amplitude modulation working. Closing the NET switch puts B+ on the 5763 only. This gives an indication of the crystal frequency with the receiver, and will also allow tuning for grid current.



When the transmit/receive switch is at transmit, B+ reaches both stages. Turning this switch to receive takes B+ off. Spare contacts can operate the antenna changeover relay. This is useful for phone contacts because this switch can control modulator B+, transmitter, antenna, and receiver muting circuits through a relay.

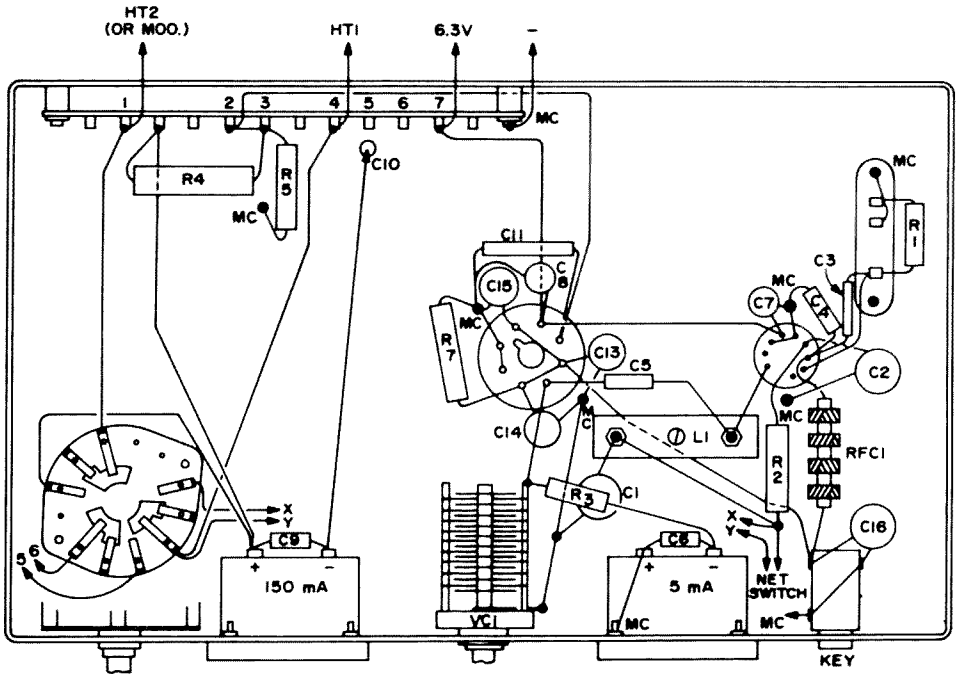
Building It

A chassis 10x6x3 in. seems suitable, with pi tank and other output components on top (Fig. 2). To obtain a short rf return, a stout lead joins rotor tabs of C2 and C3/4 together, and to a tab at the 6146 holder.

The meters, C1, Net switch, T/R switch, and key jack fit on the front runner. Figure 3 is the underchassis.

Leads not intended to carry rf (those to heaters, B+ circuits, key jack and meters) run against the chassis. Bypass capacitors go directly from the holder terminals to the chassis lugs. In particular, have very

Chassis carries grid and plate meters on front. The 6146 PA runs 20–60W input.



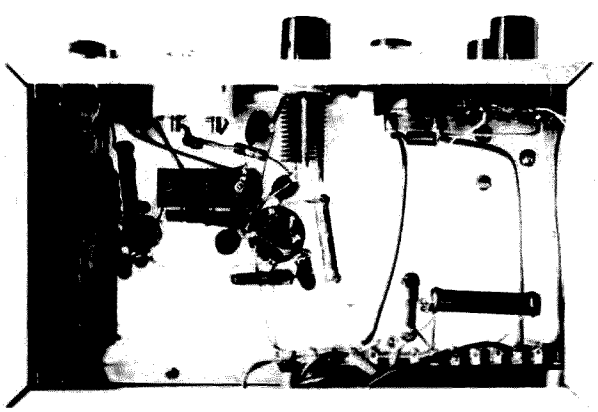


Fig. 3. Under the chassis.

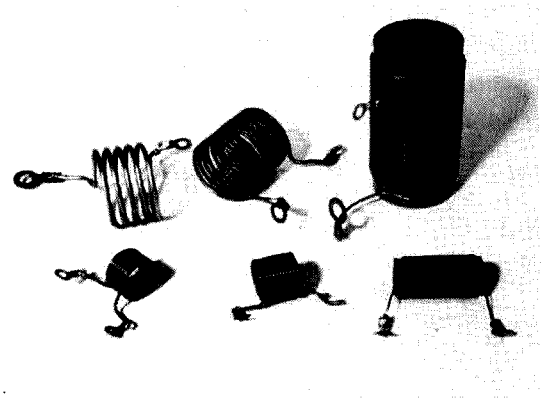
short leads from the 6146 to C13, C14, C15, and C11, and to chassis.

The B+ circuits must be well insulated, especially for the higher voltage. Should you practice high-level modulation of the 6146 with a 600V supply, the peak B+ swing will be 1.2 kV; hence, the need for insulation for this voltage, and the use of high-voltage reliable mica capacitors for C10 and C12.

A terminal strip anchors power and other leads (Fig. 3). For high-level modulation, bring modulated B+ to terminal 1. The modulator should give about 30W of audio, for 60W power amplifier input. To modulate the screen grid, the single 6BW6 or similar output stage will do. Remove the jumper between terminals 2 and 3. Modulate at terminal 2. Be sure switching cannot apply screen-grid voltage when B+ is not on the other circuits.

Underneath. The 5763 oscillator coil attaches to two bolts on insulated strip for bandchanging.



Power Requirements

The heaters need 2A at 6.3V. The 5763 crystal oscillator will work with about 200–300V. It draws 30 mA at 300V. A separate receiver type power supply is good for this stage, though it is possible to work with a single supply for both stages.

The 6146 supply may depend on what is available. Good results at a lower input rating are obtained with 300–400V, though 500–600V will naturally give more input and output power.

Though any usual supply is practical, the best type will have a choke input from the rectifier, with bleeder current consumed by a resistor across the B+ line. Then the voltage will not soar during intervals when the transmitter is not drawing current.

A capacitor-input power pack gives more voltage from a particular transformer secondary, but unless quite a heavy bleeder current can be spared, the voltage rises badly "off load."

Oscillator and output tank coils for 28, 21 and 7 MHz. Pair of coils for 14 MHz are on transmitter.

Inductors

L2 is 5 turns of 18-gage, 3/8 in. outside diameter and 5/8 in. long, with R6 inside. L1 and L3 are fitted in pairs. Changing them simply needs four nuts to be removed. This lets you work one band if that is all you want, or use other bands if you wish.

Coils for L1 can be close-wound on insulated tubing, or self-supporting for 28 and 21 MHz. If turns are as in Table I, wrong harmonics are not likely to be tuned. It is as well to check the band tuned by L1 with an absorption wavemeter, which will cause a dip in grid current (shown by the transmitter grid meter).

L3 tank coils are self-supporting for the HF bands. Though the 6146 will double, this is bad practice. So L1, and grid drive, is always on the wanted output frequency.

Operating Procedure

Those crystals which multiply up into the wanted part of a band can be used where they provide enough grid current. So some low-band crystals will allow working on one or more HF bands as well. As an example, a 3.55 MHz crystal will do for this frequency, and also 7.1 MHz. Similarly, a 7.05 MHz rock would do for 7.05, 14.1 and 21.15 MHz. A 3.5 MHz crystal gave better than 4 mA grid current on 14 MHz, and a 7 MHz crystal about 4 mA on 21 MHz. Grid current is greater at the fundamental, or with only 2X multiplication.

Always tune for at least 2 mA grid current,with the NET switch putting B+ on the oscillator only. If enough grid current is not obtained, the crystal is unsuitable. A 3.5 MHz crystal will not give enough output on 21 or 28 MHz.

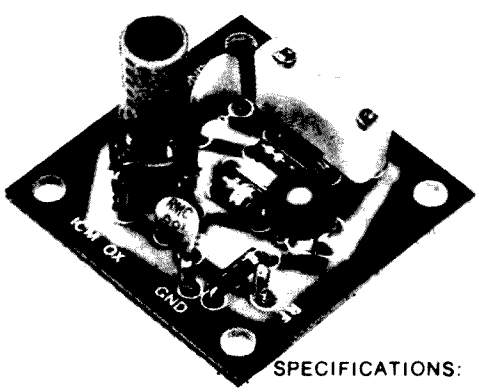
A 60W domestic lamp as load will check rf output from the transmitter, but not for keying, due to changes in cold and hot resistance. For this, a 75Ω dummy load can be connected.

Close C3/4. Tune for grid current. Open the NET switch. Switch to transmit and immediately tune C2 for minimum current as shown by the meter. Increase B+ input by opening C3/4 while readjusting C2 for the HT dip. As this proceeds, plate current will rise, and the lamp will light with good brilliance.

Check grid current as necessary, readjusting C1. The 6146 is not neutralized, and tuning its plate circuit causes some change in grid current, especially on the higher frequencies. This has no great effect on results, as grid current is always seen and easily adjusted.

When loading the transmitter to an antenna, tuning up can be as described. A dipole cut for the wanted band is probably a good antenna with which to start. With other types, if adjustment of C3/4 does not allow satisfactory loading, then the antenna impedance is outside the range of the transmitter. The best solution is to add a match box.

The 6146 should not be left operating in conditions in which it has a high dc input, but little rf output, because the power is then dissipated *inside* the tube. This is avoided by always having at least 2 mA grid current, and dipping C2 for minimum B+.



To use a vfo, remove the crystal and C3. C4 can be 0.002 μF. Take the vfo output through a screened coax lead to the 6763 grid. Plugs in the crystal sockets will do this and ground the coax shield at the transmitter. It is usually best to apply drive at a frequency which lets the 5763 multiply. For example, at 7 MHz for 14 and 21. A two-stage vfo with fundamental operation on 1.75 and 7 MHz was found to do for all bands, 3.5 to 28 MHz.

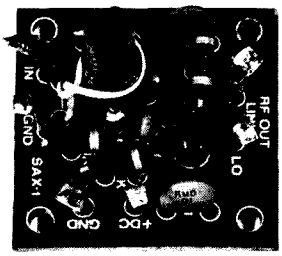
JUST LOOK AT WHAT YOU CAN DO WITH THOSE LITTLE INTERNATIONAL CRYSTAL KITS!

Since I have been building some kind of solid-state unit such as an i-f amplifier, an rf power stage, a solid-state X-band oscillator, etc., at an average of about one a week, I appreciate an organization that is marketing kits for us amateurs in a sensible fashion. Frankly the prices don't appear sensible, being much, much too low! For $2.95 you get a complete crystal oscillator kit (3–60 MHz). You don't get the crystal at that price, but you do get the transistor, and the oscillator works right off the bat.



You can follow the oscillator with an rf power amplifier for $3.75 that puts out 200 mW up to 30 MHz and will light a pilot lamp brightly. Any time you can light a bulb you can have QSO's. With a 201A and 90 volts of B battery I used to work all up and down the East Coast every night. Of course I was in Bermuda, parked just *outside* the American band, and it was 1925. I'll bet it can still be done today.

The nice thing with these kits is that you can put them on the front seat, either with dry cells or the car battery and drive up on any hill, put a small beam on top of the car, and away you go. Don't just go up there with a halo or a whip, please! Try something with a little more sock to it. Battery operation plus a hill plus VHF equals DX.

SPECIFICATIONS:

1. Frequency Range	LO—3000 KHz to 19999 KHz HI—20000 KHz to 60000 KHz
2. RF Output	.2 volts rms into 50 ohms (min)
3. DC Power Required	6 volts at 20 ma (operates 4 to 9 volts)
4. Frequency Tolerance with OX and EX Crystal	.02%
5. Operating Temperature Range	0 to 50 Degrees Centigrade
6. Frequency Change with 1 Volt Supply Change	.001% (max)
7. Output Level Change with 1 Volt Supply Change	2 DB (approx)
8. Size	1½" x 1½" x 1¼"
9. Mounting	4 holes with spacers or fits over 1¼" chassis hole
Complete Kit (less crystal)	**$2.95**

Fig. 1. OX oscillator kit specs.

OX-oscillator

You probably know by now that my fun begins on six meters and goes on up, so I'm mostly talking 50 MHz to start with. If I did try one of those little rigs on 40 or 20 who knows what I could work?

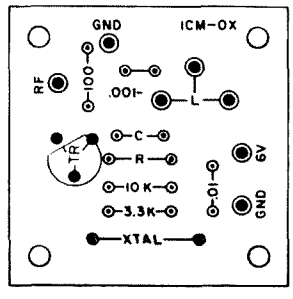
The OX Oscillator Kit.

There is a certain fascination about these little kits that grows on you. It could be due to the absence of cerebration needed, something like a vacation for me, as most of the work I do on this well-worn bench does require at least a little.

When you get the kits you receive a four-page instruction folder with good, simple dope and the circuit. You also get a very neat little copper-clad phenolic board which not only has the actual circuit on the copper side, but clear and well-printed names of the components on the other side. It is *almost* impossible to go wrong. I did. If I had read every word on that little four-page sheet I would have been fine, but I hurried a little too much. There is a just slightly tricky spot if you don't read it all over carefully. This is where it says on page 2, "the remaining parts (R, L, and C) are selected according to the frequency range from the chart below." What they mean is that this particular selection is done at the parts packing stage in Oklahoma City. And it was done exactly right for the "OX-HI" kit I ordered. Just read every word and think it out with the aid of the board and the schematic and you won't go wrong. Also check all the parts in the bag, recheck with the circuit on page 4, and you'll have it correct the first time.

Be sure of this, because it is *not* handy to replace or change parts that are soldered in place. Plan to do any experimentation *outside* the board.

As soon as I got those little parts "selected according to frequency" installed (my fault entirely on that one) and threw the battery switch, bingo, 3V dc output on the meter of my trusty old 25 to 75 MHz tuned diode receiver-rf meter.



One actual omission in the instructions did show up. I've just read everything over again once more to be sure this one wasn't my fault also. Several loose connections showed up as intermittent oscillation, and these were in "the connector pins that have been staked into the board at the factory" department. As soon as I *soldered* them onto the copper circuit, operation was steady as a rock and has been since then.

The instructions are pruned down to exactly the minimum possible number of words and still get the correct ideas over. The exact quantity of all the parts needed, including "1 jumper wire, No. 24, 1½ in."

The circuit , as can be seen in Fig. 2, has everything you need. It will be interesting to see just how far you can go up in frequency and power using these little planks exactly as they are.

Planned Systems

My first intention is to build up a complete six meter rig similar to my faithful

OX Hole Layout

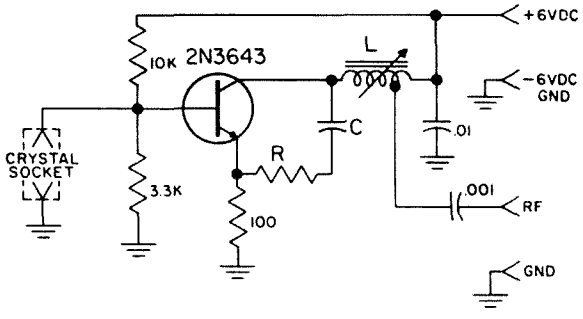


Fig. 2. Layout and schematic, OX-oscillator.

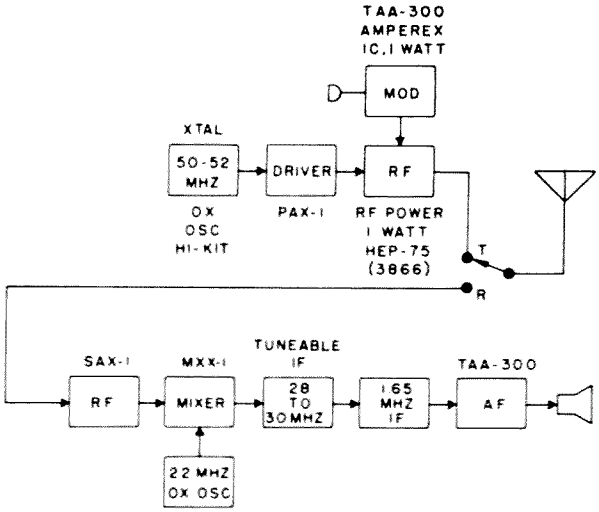

Fig. 3. Diagram subject to revision

old Gonset Three (Fig. 3). The biggest mistake I ever made in radio work was to sell that unit. Plugged into the ac at home or into the 12V battery in the car, mobile or mountain top, I could listen to all the lads on the air and could contact them. So maybe now I'll have a solid state replacement for it. I sure hope so.

There is a slight hiatus coming up though, because the power amplifier kit, PAX-1, says it only goes to 30 MHz. There is also the broadband kit, the BAX-1, to work with, which claims to go to 150 MHz with 6 dB gain (it does).

The receiver should go well with the small signal amplifier, mixer, and oscillator kits. There doesn't seem to be any frequency-multiplier kit. How come? Maybe the BAX-1 will triple? It will probably do well as an i-f amplifier also. Plenty to do, as you can see.

The Broadband Kit, BAX-1

This little gem (they're only 1½ x 1½ in.) was tried with the 50.5 MHz input from the OX oscillator kit. No good. Like the instruction sheet said, it is limited. I should confess right here and now that I'm not exactly a broadband type. With a scope a broadband amplifier is not only good, it's a necessity. And this little plank does amplify small signals, and well, too. I checked it out with my signal generator and it really does amplify, several hundred times, just as they claim. I'm sure going to try it out in the i-f stages when I come to that part of the receiver for the complete six meter rig.

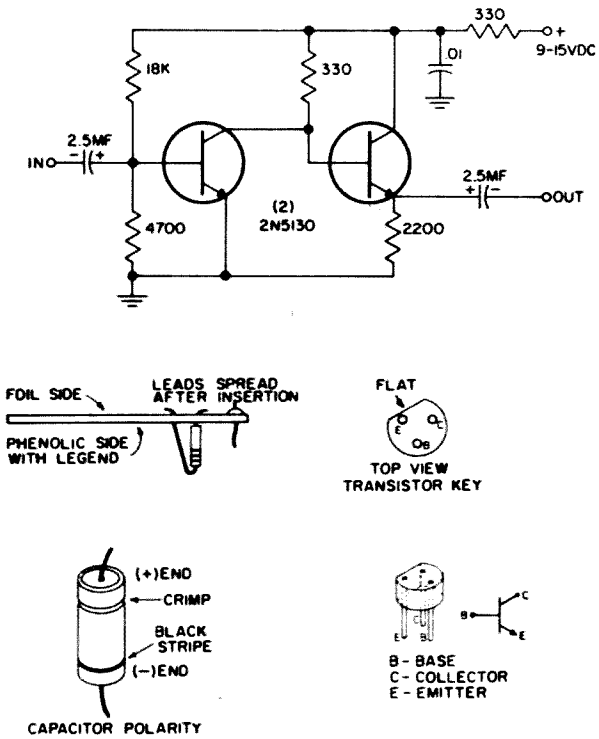

Fig. 4. Broadband amplifier BAX-1.

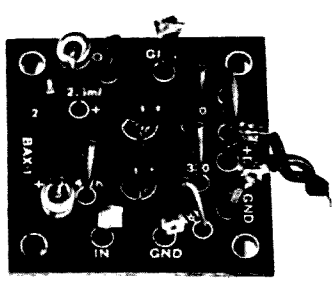


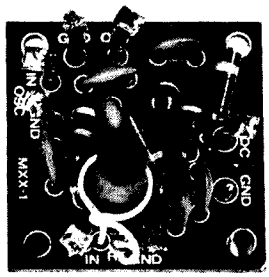
They ought to say whether or not there is any nuisance feedback in it for such an application. This is the thing called "reverse transadmittance" by the engineers in charge of such things in big companies.

I might add that it took me less than an hour to solder in the parts and have it working.

When you consider that it does amplify whatever signal you put into it, over a tremendous range, without inductors and without tuning, it's quite a nice little unit. I'm sure I will find a use for it soon, other than as an i-f.

The rf Power Stage on Six

Since International Crystal did not have an output stage on six, I threw a Motorola



BAX-1

transistor, the HEP 55 at only $1.20 amateur net, into the breach, and it took off like a little black plastic bandit on 50.5 MHz. Figure 5 shows the circuit, breadboard style, driven by the OX crystal oscillator exactly as is! Figure 7 shows the layout.

The OX oscillator on 50.5, one of the crystals I picked out, has a low impedance output tap so this was fed directly into the HEP55 base, through a couple of feet of RG8/U, two "phono" plugs, and J1, into a .001 capacitor, to preserve the base's dc bias. The base is fed dc through a 1K resistor, which I prefer to a choke because there is less chance of self-oscillation. So far none has appeared, so leave well enough alone!

The low value final emitter resistor was "snuck up on" in the usual fashion em-

"MXX-1" Transistor rf mixer

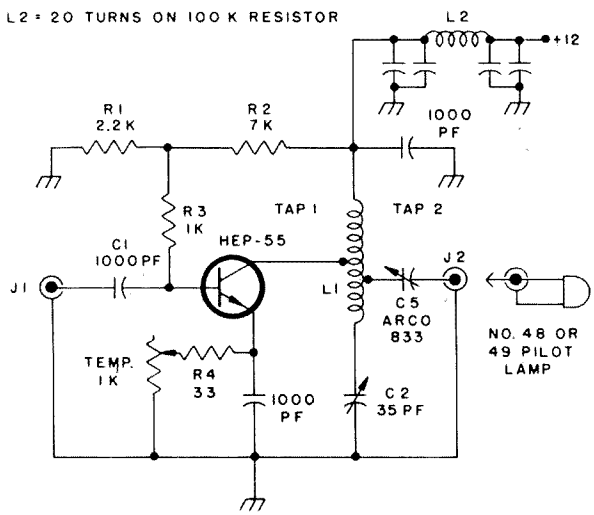


Fig. 5. Motorola HEP55 six meter amplifier. L1 = 12 turns, airwound, 6 per inch, 5/8 O.D. Tap 1 = 5 turns from cold end. Tap 2 = 6 turns from cold end.

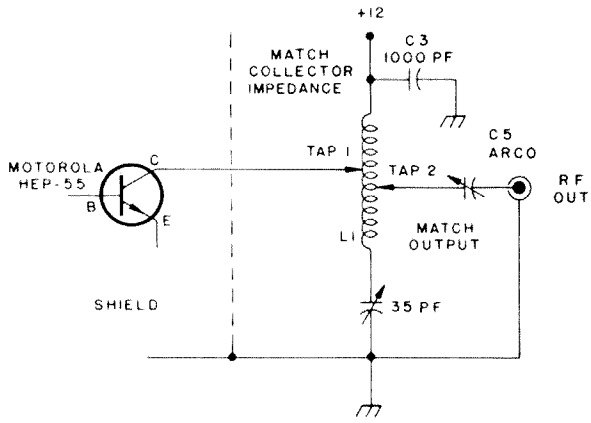

Fig. 6. Collector and output maching.

ployed here, a 33Ω series limiting resistor, along with a temporary 500Ω pot. When everything is tuned up and properly matched and loaded, but not before, you can tie the 33Ω resistor down to ground and leave out the 500Ω pot. Until that happy all matched point is reached, the rf output will tend to drop off with less than 100Ω or so. You'll see what I mean as soon as you try it.

The collector tap as well as the output tap was determined by the "empirical" method, otherwise known as "cut and try."

You should see the complicated equations indulged in by various types of engineers to get rf circuits running today! After ten pages of this stuff they announce, "The circuit was then built and tested." Results count, so don't be scared off. The above circuit using the OX oscillator drive as mentioned puts out 180–190 mW on six, from a $1.20 transistor. After all the HEP55 is only rated at 310 mW dissipation. The dc used was 15V and the mils 25, for 375 mW dc power, and thus a little over 50% efficiency on 50 MHz. What more do you want?

Figure 6 shows details of the breadboard tuning up method for the collector and the output circuit taps, which handled perfectly. As the collector was brought nearer the cold end and tuning became sharper, and the power rose. The output matching is done with a tap and a series capacitor to match the number 49 or 48 bulb impedance at six meters.

This match may change a little for use with a 50Ω cable going to a beam, but for now it loads the final in good style, for either overloading or underloading or just right for 180 mW to the No. 48 bulb.

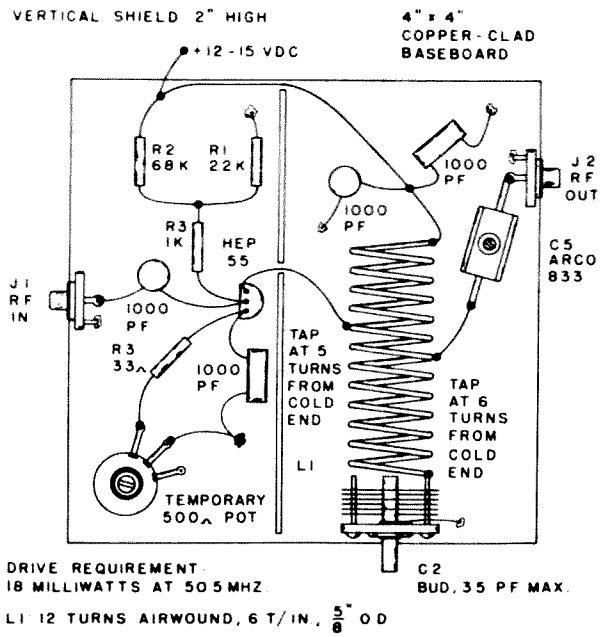

Fig. 7. Layout, six meter, HEP55 power amplifier.

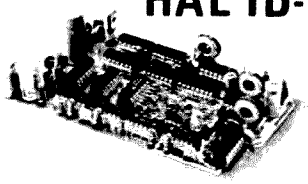
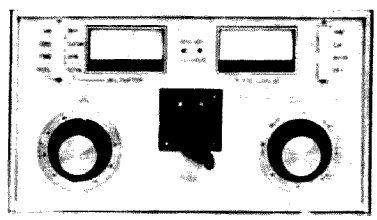
Note that when you have maximum output with the desired loading and tuning, you will also have a good match. They go together like peaches and cream. This does *not* mean the maximum without varying both taps 1 and 2, referring to Fig. 6. It *does* mean that when both taps, tuning, collector loading and current, have been run through in combination several times and no more gain and power out can be obtained, *then* you are matched.

Pushing the OX Oscillator (Just a little!)

Busy tuning up the HEP55 final I noticed that the output of the OX crystal job, when pushing it along with 9V (sometimes 10 or 11 I'll admit) seemed almost enough to light a bulb, but I couldn't quite see a glow, even with the lights out. This is the good old 2V-60 mil pilot light No. 48 screw base type, or the 49 bayonet type, which starts to glow a dull red around 17 or 18 mW. So, after swearing that I would not touch that gem of a circuit by ICM, I gave in and lowered the emitter resistor a shade. See Fig. 2. It only needed just a touch, like down to around 75 Ω to light that bulb. When I can *see* the rf I feel much better.



A little later I tuned up the "L" better with the slug and found that I could light the bulb with the exact circuit of Fig. 2 without changing the 200Ω resistor. I also find that I have about 11V dc on it. ICM says 4 to 10, so maybe that's a little too much. After all, if you want more power, add a power stage, which is of course just what the HEP55 is in there doing, so don't push that one tiny little oscillator transistor off the shelf!



Conclusion

Everything going fine so far . . . next comes modulation, size reduction, then the receiver, a mobile six meter beam idea, and then a little mountain topping to try the rig out.

Lots of interesting extras can be dreamed up for this one, too, like; A, adding a Motorola HEP75, which is their version of the famous 2N3866 for only $2.95, "suggested net," with a 3 to 5W dc input capability that works good at 432 so no knowing what it will do at six, but I'll soon find out; B, a low noise input rf stage; and C, a narrowband i-f following.

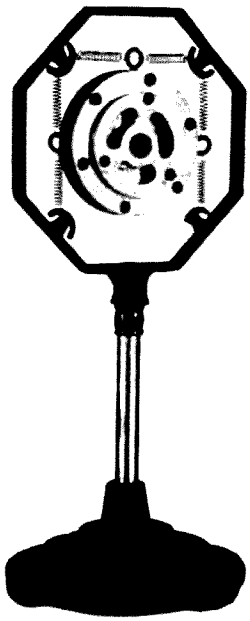
"My advertising money was absolutely wasted!" That's what one manufacturer who tried ads in all four ham magazines told us about the results he got from one old and well-known magazine. This chap, trying to launch a new product of interest to VHF men and home builders, had no money to waste on advertising that didn't pay for itself and could ill-afford a setback like that. You'll find his ad running in this issue . . . 73 paid off for him and paid off well . . . the others didn't! The results elsewhere ran from "absolutely worthless" to "didn't pay for itself."

This chap is lucky, in a way, because he is selling his products by direct mail and he found out immediately which magazine was selling for him and which was just using up his valuable capital, slowly running him out of business. Pity the larger manufacturers who buy their ads on the basis of how old a magazine is, how much gall the publisher has at circulation swearing time, or how much of a discount they can get from the regular rates. He passes along this tremendous waste of money to his customers in higher prices and then wonders where the profits went.



Does it make any sense that 73 readers buy more ham gear than the readers of the other magazines? Just think over the general slant of the four ham magazines for a moment and see which seems most slanted toward the probable active and buying amateur. How about one aimed at kids and certificate hunters? Will they be good buying customers? Will a magazine aimed at conservative old-timers be a rouser at the cash register? How about one that interests engineering-type home builders marching to the tune of "build, don't buy!"

Only 73 is edited and published by an active amateur . . . a ham who is on the air daily and who has worked with enough different aspects of the hobby to write books on several of them . . . a ham who has represented the U.S. at Geneva at the I.T.U. . . . a ham with over 30 years of hamming behind him. Only 73 has a sense of humor, realizing that amateur radio is a hobby and is for fun . . . as soon as the fun goes out of it the hobby will die. Only 73 carries the ball when new developments turn up . . . 73 pushed sideband when it was new . . . pioneered transistors years before the other magazines . . . pioneered ICs . . . pioneered RTTY . . . pioneered ATV . . . and now is publishing more FM info than all other ham magazines combined, times two . . . and watch 73 for SSTV developments! Only 73 has newspages for the non-technical amateurs so they can keep up with current amateur events.

It's true that QST still has more circulation than 73 . . . but for how long? Our special book offer circulation drive is keeping us busy and the circulation is going up faster than ever before . . . watch out QST! Activity of the readers means a lot more than sheer numbers, as the mail order advertisers have discovered . . . which is why they are advertising in 73 . . . many of them ONLY in 73!

The Saga of Mikes and Earphones

Late in the 1870s, a Boston inventor was so stunned by Bell's creation of the telephone that he suffered with insomnia for a whole week. "If Bell had known any more about electricity," he fumed, "he could never have invented the telephone." In one sense he was right. Electrical knowledge of the day was restricted to make-and-break devices. Strict obedience to what in that day was thought to be hard and fast rules would have rendered telephones absolutely impossible. As is generally the case in the birth of any major device, Bell was not primarily an electrician, and so was not hampered by convention.Bell knew one thing, however, that the electricians of his day did not know. That was the exact nature of human speech. His father had been an expert in the subject before him. Moreover, Bell had actually made tracings of the vibrations of speech by connecting a diaphragm to a movable pen which rested on a paper strip. He knew what to shoot for before he started, a current which could vary exactly as the air pressure varied when transmitting sound waves.

The big idea came to him through a lucky accident while working on a multiple telegraph system. A series of metal strips, each tuned to vibrate at a different frequency, would be set into motion in the field of an electromagnet and caused a similarly tuned strip to vibrate at the other end. Bell's assistant, Thomas Watson, was having difficulty at the transmitting end. His struggling with a jammed reed set up a racket in the receiver which Bell was smart enough to interpret. "Don't change a thing!" he shouted to the startled Watson, and began scrutinizing the apparatus. The infant idea was developed and a a patent granted nine months' later. Bell's first telephone consisted of a diaphragm which vibrated a piece of soft iron within the flux of an electromagnet. The changing flux allowed the current flowing through the electromagnet to undulate. It worked, although very faintly. Bell also tried attaching the diaphragm to a rod immersed in a container of acid. The vibrations of the diaphragm moved the rod in and out of the conducting acid. A battery connected in series with it saw an undulating resistance, therefore, an undulating current. It was over this monster that the famous distress cry ("Mr. Watson, come here. I want you.") was delivered. Bell had spilled some acid and was in pain from it. Now Bell was not an American citizen at the time, and so he did not have the option of filing a *caveat*, or declaration of intention to invent the device.

He had to patent a working invention or forget it. Two hours after his patent had been entered on Bell's behalf by his future father-in-law, another inventor filed a caveat for an almost identical device. Elisha Gray did not invent the telephone at the same time as is commonly believed. He merely served notice of his *intention* to do so. In fact, Gray was later part of a committee that honored Bell, and quite glad to do so.

It's a sad thing to note, but in that day it was common for one company to pirate the rights of another and try to beat it in the courts by bribery or by out-and-out fraud. Bell found himself pitted against some of the largest corporations of his day, and, at one point, he had to fight it out with an ex-governor, a number of congressmen, and the United States Attorney General. This kind of piracy was unusual in only one way. Bell won.

With the introduction of the telephone to the public, Western Union interests nearly panicked, and for several years there was quite a bitter feud between the two. Bell and Western Union pirated one another freely. To compete with the telephone, Western Union had hired a clever young man named Thomas Edison. Edison replaced the electromagnet with a container of carbon granules. The varying pressure of the sound waves on the diaphragm caused the resistance of the carbon granules to vary. Edison's microphone was far more sensitive than Bell's. Bell used Edison's mike while Western Union used Bell's earphone. Nothing like reciprocal piracy, is there?

The battle between the two raged both in the U.S. and abroad. In England, the British patent office forbade Western Union from using Bell's earphone. Edison's patent on the microphone was useless by then since a man named Berliner had, after fourteen years of litigation, managed to prove that he had invented the same thing before Edison. He finally got patent rights, although Edison still had rights to his model. Berliner sold his patent to Bell. In England, then, both parties could use the carbon microphone, but only Bell could use the earphone.

The British rivals of Bell's company frantically cabled Edison. "Hang on," the inventor replied, and went to work on it. The answer came in the form of an "electromotograph." This forgotten child of Edison's genius consisted of a rotating chalk roller which kept a tension on the end of a rod. The rod was connected to the diaphragm. A sponge kept the roller wet. Edison had discovered that the slipperiness of wet chalk would change when electric current passed through it. As the slipperiness of the chalk roller varied, so did the tension of the diaphragm, and the diaphragm vibrated. The electromotograph had originally been invented for another application, and here it still had a lot of bugs, but it worked well enough to get a patent.

Finally, Western Union and Bell merged. The Western Electric company was formed to construct telephone equipment, and for a number of years it had a monopoly on communications. Then came radio. In 1906, Dr. Ernest Fessendon made his first radiotelephone transmission, and startled the entire world. By the end of World War I, radio was becoming more and more available to the public. KDKA, which, by the way, had begun as an amateur station, started the first scheduled broadcasting and the rush was on.

Carbon buttons were the first microphones used in broadcasting, which is natural enough, since they were the only kind available. But carbon buttons have their disadvantages. Frequency response is restricted. Also, the necessary current offers a high noise level. First to be attacked was the frequency response. Western Electric used a stretched diaphragm to raise the resonant frequency

This meant lower output, but that was no problem. It was partly compensated by using a carbon button on either side of the diaphragm. For a few years the double button carbon mike was the standard symbol of broadcasting.

Western Electric kept a firm grip on the patent rights to the stretched diaphragm microphone until, in Watertown, Mass., Delano Co. started making them. It was a small company, and Western Electric sued. Their strongest point was the stretched diaphragm raising the resonant frequency.

Delano showed that the African savages, for years, had been stretching the diaphragms of their drumheads for the same effect. He won the case.

At the receiving end, the electromagnetic earphone had been there right from the beginning. It was, after all, a fundamental thing. To this day, it's still essentially the same instrument Bell invented. When radio became a public medium, manufacturers simply put a large horn on the output of the earphone, something like a megaphone. In the mid-20s Nathaniel Baldwin attached a diaphragm to a lever which, in turn, was connected to the earphone diaphragm. By simple lever action it magnified the motion, thereby giving a louder sound.

In the late 20s, scientists found an answer to the biggest drawback of the carbon microphone. The current through the mike caused a very high noise level – so high, in fact, that a whisper or a soft voice was simply lost in the mud. (Incidentally, this defect was responsible for the downfall of a lot of the stars of silent movies as "talkies" came into vogue.) Clearly the need was for a microphone that would have a low noise level.

The answer came in the form of the condenser microphone. The vibrating diaphragm would cause a capacity change between it and a back-plate a few thousandths of an inch away. A high voltage was connected across the capacitor, and as the capacity changed due to the varying spacing between the diaphragm and the back-plate, it would alternately gain and lose charge. Consequently, a minute alternating current would be present which exactly followed the audio. This current was detected in the form of a voltage drop across a series resistor. The output was so low that two or three amplifier stages had to be built right into the case. Nonetheless, the condenser microphone was and still is unsurpassed for fidelity and frequency response. It was put into wide use around 1934 when NBC started broadcasting.

In the meantime, loudspeakers were introduced by Jensen. The Jensen unit was an electromagnetic dynamic driver feeding a horn, and first saw light of day in the early 20s. Loudspeakers such as we know them were introduced in the late 20s as the paper cone replaced the horn. The magnet was an electromagnet until the mid-30s with the introduction of Alnico. Electromagnetic speakers remained in use for quite a while, however. I can remember seeing them in the early 50's as I took apart old radio sets. I recall that one of the more popular means of exciting the electromagnet was to use it as a filter choke in the power supply circuit.

Until the condenser microphone was introduced, Western Electric was without competition. Then they suddenly found themselves competing with a microphone that was much better suited for broadcasting. They responded with the dynamic microphone, which had a good frequency response, low noise level, and a high output. It was also far less sensitive to moisture than the condenser microphone, and needed no high voltage power supply.

About the same year as the condenser microphone was invented, an engineer at RCA named Harry Olsen produced still another microphone. This one used a thin metallic ribbon suspended between the poles of a magnet. It was the velocity of the sound waves that actuated it, rather than the pressure. While the output of the velocity microphone was lower than that of the dynamic, it had a wide, flat response.

The microphones were manufactured with two ribbon elements at right angles to one another. By connecting them in or out of phase you could alter the directional pickup pattern. This helped the broadcasters to get by one very sticky problem. The problem was best expressed in an old cartoon which showed a microphone placed at the head table of a highly publicized banquet. The voice of the guest of honor was being drowned out by the other head table guests who were loudly downing their soup. An exaggeration, maybe, but extraneous noise was a major problem in the early days of broadcast, and a directional pickup was a welcome answer. So much so that the housing of the velocity microphone, in its familiar diamond shape became an unofficial symbol of broadcasting, and still is to this day. . . .W2FEZ

QUICK AND EASY PNP/NPN TRANSISTOR SORTER

A simple tester that quickly sorts out unknown transistor types (NPN or PNP) and can be used to give an indication of relative gain for each type.

There are numerous sources of bargain transistors, such as surplus computer boards but, invariably, the transistors are marked with production numbers rather than standard 2N numbers. So, one cannot simply look in a handbook to determine the transistor type (NPN or PNP), or any of its operating parameters. Usually, however, the only characteristic of immediate interest is whether the transistor is of a NPN or PNP type, since the transistor is usually intended for experimental usage, or as a "pot-luck" replacement for another transistor in a non-critical circuit. It would be false economy, generally, to search among surplus transistors to find a unit to use in a circuit where a specific transistor is used because of its known and stable gain characteristics, noise characteristics, etc.

The simple tester or sorter described here is designed to simplify the rapid sorting out of PNP or NPN transistors while not causing any damage to the transistor under test when the test voltage polarities are reversed from those applicable to a transistor type. It provides an aural indication when a transistor corresponds to the type to which a test switch is set, so one does not have to interpret meter scales or other displays. The transistor is used in a dynamic circuit so that when the type is found, one can also have confidence that all the transistor junctions are undamaged.

Once one is familiar with the usage of the tester, transistors can be sorted out at the rate of 5–10 a minute. This is quite an improvement over the laborious VOM testing techniques used by many amateurs where one also runs the risk that excessive current flow generated by the VOM can damage the transistor under test.

Circuit

Figure 1 shows the complete circuit of the tester. It is about as simple a circuit as one can imagine, but yet it does the job. The circuit is basically that of an audio oscillator where the split primary transformer winding provides feedback coupling for oscillation. The frequency of oscillation is determined by the transformer characteristics, as well as by the time constant of the RC network in the base lead. The components used for the RC network were carefully chosen so a large value resistor could be used since it limits the base--emitter current flow when that junction is variously biased during the testing of a transistor. If one follows the polarity of the battery terminals to the various transistor terminals, it will be seen that the correct biasing of the transistor junctions (collector-base junction back biased and emitter-base junction forward biased) only

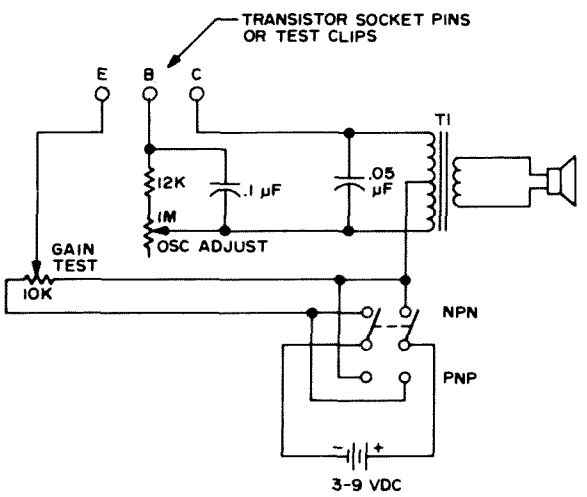

Fig. 1. Diagram of transistor type sorter. "T" is a miniature 400Ω centertapped to 4Ω transistor output transformer costing about 98¢.

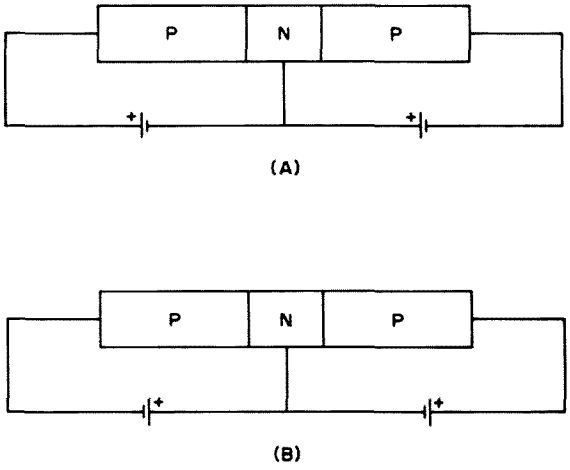

Fig. 2. Junction bias polarities must be correct for a transistor type to oscillate in the test circuit. (A) shows correct arrangement while (B) is false (for a PNP type). Sufficient base lead resistance prevents damage to transistor when improperly biased.

exists when the switch position corresponds to the correct transistor type. Only then will the circuit oscillate. Figure 2 also illustrates this point.

The combination of the low battery voltage used plus the high resistance used in the base lead insures that no damage will result to even a low power transistor during the testing process. We tried deliberately reversing the polarity a number of times on the lowest power plastic case transistor we could find without causing any damage to the unit. This was even done using a 9V battery supply.

The "gain test" potentiometer simply acts as a voltage divider network, so that the supply voltage can be reduced as desired.

Operation

A known transistor should first be used to double check that the circuit functions properly and that the switch positions for NPN and PNP have been properly marked. During this process, the oscillator adjust potentiometer should be set for a roughly 1000–1500 cycle tone. The gain test potentiometer is set for full battery voltage (arm toward left end).

Unknown transistors are then simply tested by connecting them to the tester and noting in which switch position they oscillate. The oscillator tone will vary with transistor type, but this is not important. If a transistor fails to oscillate in either switch position, the oscillator adjust potentiometer should be varied from its reference position, trying each switch position. If the transistor still fails to oscillate, the overwhelming chances are that it is defective and should be discarded.

A crude gain check can be made among a group of similar transistors by noting how much the battery voltage can be reduced, by means of the gain test potentiometer, before the transistor stops oscillating. During this check, however, the oscillator adjust potentiometer must also be adjusted so that oscillation (regardless of frequency) is sustained as long as possible.

Construction

The circuit can simply be breadboarded if only a temporary need exists to sort out a batch of transistors, or it can be packaged nicely into a minibox enclosure as a permanent test unit. In the latter case, if a DPDT switch is used which has a center-off position, it can also function as a power on-off switch for the unit since the gain test potentiometer will drain the battery supply even when a transistor is not being tested.

The idea may come to mind to utilize a code practice oscillator or CW monitor unit already existing as a test unit. Such units can work but one should be sure that the circuit utilized is similar to that shown, particularly with a high value of resistance in the base lead. Circuits with low resistance value voltage *divider* bias network for the base circuit, including most simple RC oscillators, are particularly unsuitable.

The circuit shown has performed extremely well in sorting out transistor types ranging from low power RF amplifier types to surplus digital board types to large power types. Somewhat like a VOM, it soon starts to become an invaluable test instrument for anyone dealing with transistorized equipment since even when transistors are conventionally marked, one does not always have immediately at hand the necessary handbook data to determine transistor types.

Self-Contained Reflected Power and CW Monitor

The average amateur, especially the CW enthusiast, uses only his receiver as a monitor for the outgoing signal from his transmitter. The amateur receiver usually becomes overloaded in this application and does not truly reflect the outgoing keyed signal. Also, irritating key clicks which are present only in the immediate ham shack are detected by the receiver. Not only does the receiver give out an erratic CW tone but these irritating clicks also.

If the transmitter oscillator stages are allowed to run continually to prevent chirp, the keyed signal can hardly be detected in the average receiver. The transmitter oscillator signal – being the same as that of the final – allows no distinguishable difference in the keyed tone. It is essential then that we directly sample the outgoing power and utilize this as an example of the keyed signal.

Not only is it essential to monitor our fist but also to observe the reflected power ratio. The reflected power ratio gives us an idea of how well the power leaving the transmitter is being accepted by the antenna. There is no such thing as a perfect match to the antenna and some power, no matter how small, will be reflected. The main objective is to achieve the lowest reflected power with maximum forward power. This indicates that power is being radiated by the antenna rather than generating heat within the transmitter or transmission line.

The CW monitor uses very inexpensive and easily obtainable components. The tone generating device is merely a transistor oscillator that requires only a very small amount of current to function. In theory, the oscillator requires only 1½V at 8–10 mA to function.

A small rf sample is extracted from the coaxial line going to the antenna. A 1N34 or similar diode rectifies this rf and the resultant is a dc component. Rf is prevented from coming into the oscillator section by the 470 pF capacitor connected from the plus side of the diodes to ground.

The dc that we have generated is adequate to power the entire transistor oscillator. The rf necessary to generate this dc does not necessarily have to be taken from the transmission line. A small pickup loop may be assembled and placed near the tank circuit of your transmitter. The pickup loop would take the place of the line placed inside the coax.

The audio emanating from the oscillator is at quite a low level so must be amplified to drive a speaker or headphones. An inexpensive imported transistor amplifier

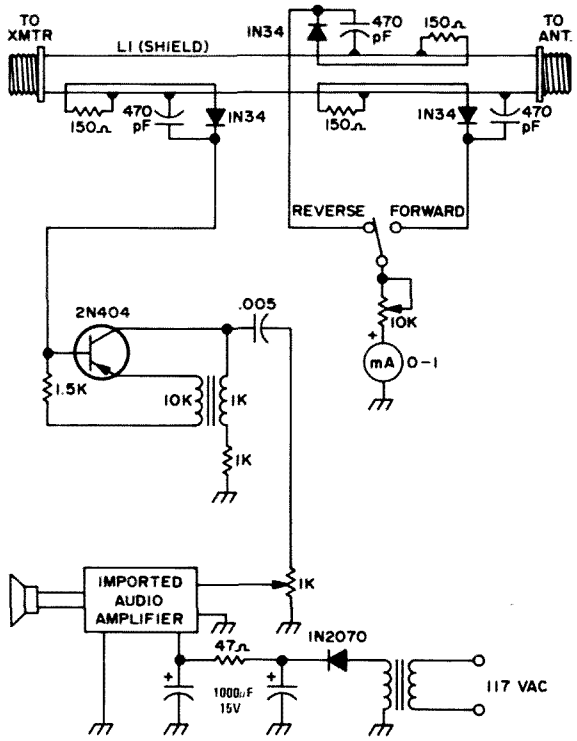

Fig. 1. Schematic diagram. L1 is a 12 in. section of RG-11/U coax with plastic cover removed. Coaxial fittings attached to each end. 5 in. pieces of #20 insulated hookup wire inserted under shield for pickup loops.

with about one watt output power was used in this application. This amplifier boosts the low level audio from the oscillator to speaker level.

The tone oscillator does not put out a pure sine wave but produces one that is rich in harmonics. This actually lessens operator fatigue over extended operating periods.

Rather than operate the transistor audio amplifier with batteries, we decided to construct a simple ac power supply. This eliminates the need for battery replacement at regular intervals. An ordinary 6.3V filament transformer was used with good results.

With the reflected power meter in the FORWARD position, the oscillator may not operate because of consumption of power by the meter circuit. When operating, leave the meter in REVERSE and the oscillator will function properly.

The heart of the reflected power meter is a 12 in. section of RG-11/U coaxial cable. All of the plastic insulation must be removed leaving only the copper braid. The sampling loops are made of 4 in. pieces of insulated hookup wire. There are three of these. One samples energy to power the oscillator and the other two are for the reflected power meter. These 4 in. pieces are inserted under the braid of the coax and the ends are left exposed about ¼ in. It is especially important that the two loops used for the reflected power meter are exactly opposite each other and are symmetrical.

If you will notice in Fig. 1, the 150Ω resistors are soldered directly to the groundshield of the coax. The opposite end goes to the diodes.

In using this device, the coaxial lead from the transmitter is attached to the transmitter end of the reflected power line and the antenna is attached to the opposite, or antenna, connector. The transmitter is then keyed and tuned properly. The calibrate pot is adjusted for full scale deflection of the meter in the forward mode. Once this is completed, switch to the reflected mode and the amount of reflected power will be indicated. If you have a good match between the transmitter and antenna, the reflected reading should be quite low. Maximum forward and minimum reflected is your goal.

When you have completed the previous steps, the monitor section can now be activated. 117V ac is applied to the power supply. This will place the audio amplifier in operation. Each time that the transmitter key is depressed, an audible tone should be heard in the speaker indicating that the oscillator is working and that there is sufficient dc to trigger the oscillator. The volume control should be set for ample volume at this point.

It is interesting to note that the frequency of the oscillator will change as the transmitter is tuned. It therefore becomes an aural tuning device also.

This dual purpose device should provide you with many pleasurable operating hours and also make the proper tuning of your transmitter much easier.

USING and IMPROVING the TEN-TEC TRANSCEIVER MODULES

A detail discussion of module circuitry, circuit improvements, transceiver packaging and operating experiences.

When the Ten-Tec series of low-power transceiver modules appeared on the market, I purchased them more out of curiosity than with any great expectations that they would be very useful. This thinking goes back to about 1950 when my "large" 100W rig became inoperative, leaving only a 3W vfo–exciter available for QSOs. I had so much fun with the 3W rig on 40 and 20 CW that there followed over the years a continuous desire and search for the circuitry and components to build a truly portable low-power CW transmitter/receiver.

Of course, with tubes, one problem followed the other of trying to keep the battery drain low while still achieving a reasonable power output, trying to extract stable performance from a regenerative receiver on the higher-frequency bands, compromising on crystal-controlled transmitter operation instead of vfo because of oscillator stability problems, etc. The result was never very satisfying, nor economical. Even some of the best "spy" type HF transmitter/receivers built in WWII never resolved all the problems involved, as became apparent later when some of the more widely produced types found their way to the surplus market or into museums.

So, with this background in mind it was very surprising to experiment with the simple and inexpensive Ten-Tec modules in

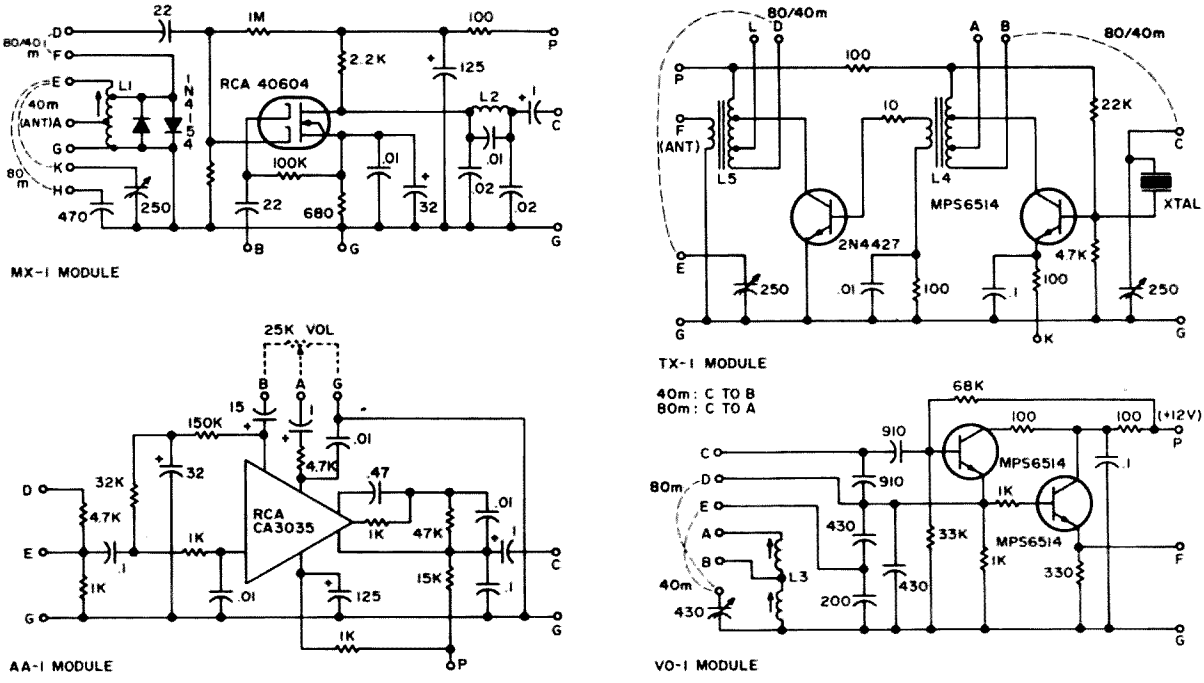

Fig. 1. Diagrams of the original unmodified four modules for the Ten-Tec 80/40 meter transceiver.

an attempt to build a truly compact transistorized and portable CW transceiver and to find that they performed amazingly well. Of course, low-power operation will remain low-power operation regardless of whether tubes or transistors are used. No 2W transmitter is going to sound like a 100W rig regardless of how good it keys, etc. Nonetheless, with a change of operating habits tailored to low-power operation, and that is probably the key to enjoying low-power operation, many satisfying QSOs can be had.

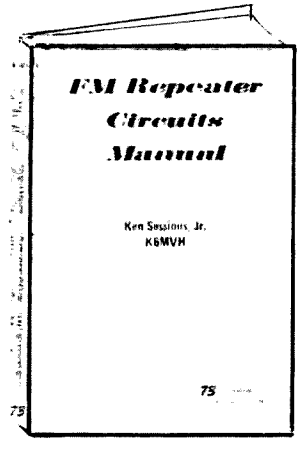
Basic Modules

Figure 1 shows the schematic of the transceiver modules with their actual PC board terminal designations so one can easily understand the interconnection points for the circuit modifications described later. The individual modules are the VO-1 vfo which can be wired for either direct output on 80 or 40 meters and consists of the basic oscillator stage and a direct-coupled buffer output stage.

The TX-1 is a two-stage transmitter which can either be crystal-controlled or driven by the VO-1 at approximately a 2W input level with a 12V battery. The TX-1 can be set for straight-through operation on 80, 40, 20, or 15 meters by means of the coil taps provided. The MX-1 is a dual-gate MOSFET product detector circuit with an approximate 2 kHz audio filter for selectivity in its audio output channel. As with any product detector, it requires an injection voltage (bfo) at its operating frequency which in this case can be provided directly by the VO-1 module on 80 and 40 meters. The taps on the input circuit of the MX-1 allow it to be set for 80, 40, or 20 meters. Operation of the MX-1 below 20 meters is not recommended by the manufacturer because of its greatly lowered sensitivity. Of course, a converter can be used ahead of the MX-1 to bring another band down to 80, 40, or 20 for use with the MX-1. The AA-1 module is simply a very high-gain (100 dB) audio amplifier that provides enough gain to drive any headphone in the 0.1–2 kΩ category to ear-splitting volume.

80 and 40 meter Operation

The interconnection of the modules for operation on 80 or 40 meters is quite simple by following the manufacturer's instructions. The VO-1 feeds the TX-1 and



MX-1 modules simultaneously. The original interconnection instructions called for a 50 pF capacitor from the VO-1 output (terminal F) to the TX-1 (base of the MPS6514 via the lower contact on the crystal socket). Latter instructions call instead for only a 3.3 kΩ resistor since the TX-1 when keyed was found to pull the frequency of the VO-1 quite a bit. The manufacturer now recommends this change. The antenna used is switched back and forth between the TX-1 and MX-1. No tone can be heard in the headphones during transmit because the product detector is always tuned to the same frequency as the transmitter. However, to eliminate the annoying thumps heard, terminal E on the AA1 can be grounded during transmit. Switching of the 12V supply to the AA-1 to quiet it, does not work well because the large capacitors used cause a time delay when the unit is switched on before the gain comes up.

One of the most immediately noticeable difficulties in operation is the limited bandspread provided by the VO-1 module. It covers far more than the entire 80 and 40 meter bands in one half-turn of the vfo capacitor. It is unlikely that most users will require this sort of coverage if they are interested in just the CW portions of the band. The solution is quite simple. The 430 pF vfo variable capacitor is replaced by a 150 pF capacitor fully meshed, the slug of the 80 meter vfo coil (bottom slug in coil can) is adjusted to place the vfo output at 3500 kHz and the slug of the 40 meter vfo coil (top slug in the coil can) is used to place the vfo output at 7 MHz. In this manner, just the CW portions of either band is covered and the ease of tuning is greatly improved. If one were to also add a 6:1 gear reduction drive to the tuning, such as that provided by the inexpensive ($1.50) Jackson Bros. reduction drives, a really excellent tuning system would result. A further modification to the VO-1 would be to regulate the supply voltage to the unit. Although regulation is not required when using fresh batteries to power the transceiver, after some hours of operation the internal resistance of two series-connected 6V batteries, or three series-connected

REPEATER CIRCUITS MANUAL

If you're into FM, you'll want to have this incredibly complete manual of FM circuits. You don't have your own repeater yet? Well, you've been thinking of it . . . admit it. Some fellows even have gone so far as to have a repeater in their car so they can extend the range of their hand units!

This book, over 300 pages long, has just about every circuit that you could possibly want. Many of these have been published elsewhere, but many haven't, too. And you can go out of your mind trying to find a circuit when you want it . . . so here they are, all in one handy place!

ONLY $6.95 ppd.

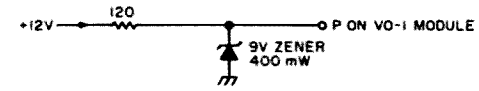

Fig. 2. Simple zener regulator improves transceiver stability greatly when battery supply starts to become "soft" after several hours use.

4.5V batteries, does build up and vfo chirp during keying becomes apparent. The simple solution is a 9V zener regulator for the VO-1 module, as shown in Fig. 2. Reducing the operating voltage of the VO-1 to 9V from its nominal 12V did not produce any noted reduction in output of the TX-1 module, nor in the receiving sensitivity of the MX-1 module.

Another simple addition to the modules when they are used on either 80 or 40 meters is a keying monitor and a transmitter rf output level indicator. The manufacturer does produce a keying monitor in two forms. The AC-2 module is just a keying monitor, but it is a bit elaborate and expensive as compared to the other modules for the purpose of providing just basic sidetone.

The AC6 module is a better value since it contains for about the same price not only a sidetone oscillator, but a VO-1 doubler (discussed later). However, the doubler circuit is not needed for basic 80/40 meter operation. The AC-6 keying monitor is also of the phase-shift type which produces a very good sine wave output, but is a bit superfluous when only

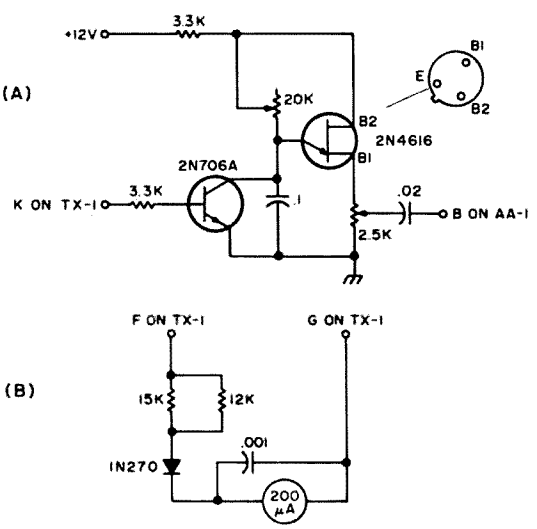

Fig. 3. CW monitor (A) with adjustable tone and volume and rf output level circuit (B).

basic sidetone is required for a portable transceiver. The use of a 300 mA meter in the battery supply lead for tuning purposes, as recommended by the manufacturer, is certainly easy to use and does give a continuous indication of the input level to the TX-1 module. However, when dealing with such a low-power unit, it does appear advantageous to instead have a tuning indicator which shows that the maximum possible power output is being obtained.

Figure 3 shows the CW monitor developed by the author, as well as a simple rf level output monitoring circuit. The CW monitor, if one disregards the 2N706A, is seen to be a very simple unijunction sawtooth oscillator. The output is fed to the AA-1 module, but beyond the point where the volume control for the AA-1 module has effect. Thus, the sidetone volume will remain constant regardless of how the AA-1 volume control is changed during receiving. The 2N706A stage operates as a switch controlled by the TX-1 keying terminal voltage. Under key-open conditions, about 3V is developed across the key terminals. This voltage applied to the base of the 2N706A causes the transistor to "short" the .1 μF capacitor in the 2N4616 emitter lead and that stage cannot oscillate. Under key-down conditions, the 2N4616 stage is free to oscillate. The monitor circuit produces a very cleanly keyed sidetone because of the 2N706A switch. The output frequency is adjustable by varying the 20 kΩ potentiometer in the emitter lead and the output level by varying the 2.5 kΩ potentiometer in the base 1 lead. The rf output level circuit is simply a series rectifier circuit employing a sensitive 200 μA meter connected across the link output of the TX-1. The high series resistance used insures that the circuit will have no effect upon the low impedance output loading of the TX-1. It is used the same as any rf output level circuit, with the tuning capacitors in the TX-1 both simply being adjusted for maximum output level on the meter.

The performance of the transceiver on 80 and 40 meters, once the above modifications have been made, is very satisfac-

tory. Keying is good and the stability during receive is excellent. SSB reception can be done quite easily with the expanded bandspread tuning. The CW reception is really surprising and one wonders how so many signals can be heard with even the simplest of antennas using such a simple receiver. The answer is perhaps not hard to find when one considers the high conversion efficiency and low noise factor of the MOSFET used in the MX-1 module, plus the extremely high gain of the AA-1 module. The mating of the MX-1 and AA-1 modules is very well designed. A 1.0 μV or less signal on CW can be copied quite easily. A comparison of the MX-1 and AA-1 combination to any expensive communications receiver will, of course, demonstrate the superiority of the latter. However, the comparison of the modules to several of the medium price range receivers, or receiver portions of inexpensive transceivers, is rather disturbing. Not only does the module combination seem to perform just as well on CW but the freedom from spurious mixer responses, images, etc. provided by the module combination is really refreshing on the extremely crowded, BC infested lower frequency bands. It is a rather new experience to again be confident that what one is hearing is really on the frequency being received, rather than the creation of poor receiver design. The CW selectivity of the modules is not adjustable since it is determined by the audio filter in the output of the MX-1 module. However, one can adjust the slug in the large inductor (L2) of the MX-1 to vary slightly the audio frequency filter bandpass to a setting more suitable to individual preference. The audio gain of the AA-1 is so great that a sharp audio filter such as the surplus and inexpensive FL-8 can easily be added between the MX-1 and AA-1 when space is available to provide extreme audio selectivity without any additional circuitry.

Operation on 20 and 15 Meters

The first inclination when one investigates the usage of the modules on 20 meters is to be a bit critical of the manufacturer. The TX-1 and MX-1

REPEATER BULLETIN

As a reader of 73 you may be interested in the newest FM bulletin . . . the Repeater Bulletin. This magazine is published by 73 Magazine just for the users of repeaters, particularly in the New England and Eastern New York areas and it carries news of activities of the repeaters covering this section of the country.

In addition to news from the repeater clubs the Repeater Bulletin will carry maps showing the coverage of the repeaters, discussions of the problems faced by repeater groups . . . discussions of frequency coordination, of functions being added to repeaters, of whistle-on, of tone burst, of touchtone, and continuous tone coding and decoding . . . antennas . . . coverage of repeaters . . . hints for mobile installations . . . cross-band links . . . circuits of value to both users and repeater owners . . . a bibliography of the articles being published on FM . . . discussions of new equipment being brought out . . . ideas for repeater development . . . new frequencies . . . 220 plans and developments . . . 450 repeaters and their problems . . . problems faced by FMers in other areas of the country worthy of consideration in the North East . . . news of club meetings . . . symposiums . . . conventions . . . dinners . . . auctions . . . swapfests . . . and other social events . . .etc.

The Repeater Bulletin is available absolutely FREE to every repeater user in the New England and Eastern New York areas . . . just send in an application form for qualification indicating that you are an active user of FM. If you live outside of this area (if you are unable to use any New England repeater), the Repeater Bulletin is still available, but at a subscription price of $2 per year.

If the Repeater Bulletin is successful, it is always possible that its coverage may be extended to cover more of the country or that other regional editions could be published. We have all of the facilities here at 73 to turn out publications such as this quite economically, so we may be able to provide a communication medium if it is needed in other areas.

The Bulletin is in a large format (8½" x 11") and runs 24 or so pages per month.

Repeater Bulletin Subscription Order Form

☐ I am actively using a New England Repeater and wish a FREE subscription.
☐ $2 is enclosed for a one year subscription to the Repeater Bulletin.

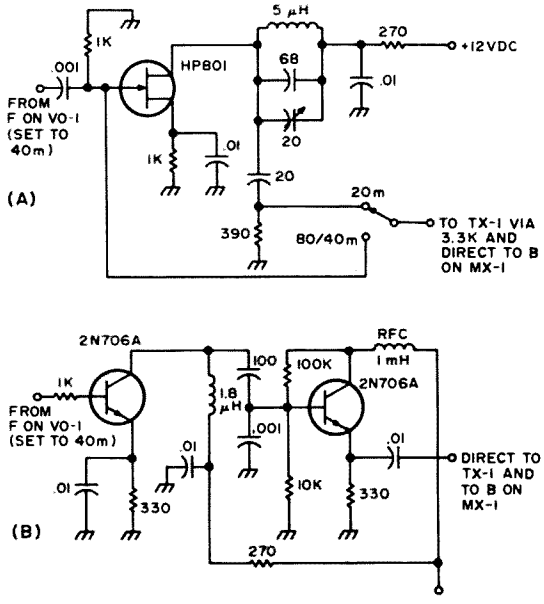
REPEATER BULLETIN PETERBOROUGH NH 03458

Top view of the four basic modules as packaged by the author into a single band transceiver. Details of modifications made are discussed in the text.

The power supply for the author's portable transceiver consists of three 4.5V flat batteries held in the top cover of the transceiver enclosure.

modules cover 20 meters with their tuned circuits but the VO-1 module output must be doubled to provide drive to the TX-1 and an injection voltage for the MX-1. It would seem that better design of the VO-1 could have provided this simple feature. However, some consideration of the modest cost of the modules must also be included.

The manufacturer does provide a module (AC-6) which contains a frequency doubler for the 40 meter output of the VO-1, plus a CW monitor. However, a simple frequency doubler can be constructed, as shown in Fig. 4, which will also serve the purpose. The FET doubler shown in Fig. 4(A) provides about 2V at 14 MHz which is more than adequate for the TX-1 and MX-1 modules. However, even when using this FET circuit there was found to be noticeable "pull" on the frequency of the VO-1 unless the drain circuit of the FET was carefully tuned so that the output frequency of the TX-1 remained the same under key-down conditions and under key-up conditions when only the feed-through of the VO-1 and the doubler could be heard in a receiver. A less critical circuit is shown in Fig. 4(B). This two-stage doubler provides a broadband doubler, plus a buffer stage, so pull on the VO-1 is eliminated when the frequency of the latter is doubled from 7 to 14 MHz.



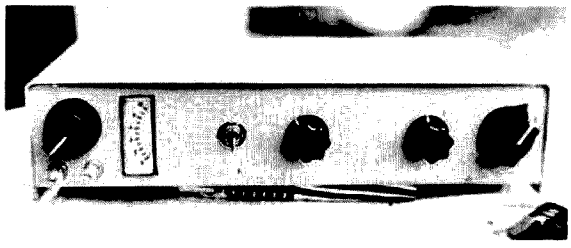


Fig. 4. FET doubler circuit (A) to convert 40 meter VO-1 output to 20 meters. Dual stage circuit (B) provides better vfo isolation and can also be used as tripler for 15 meter operation.

Operation of the modules on 15m becomes a bit more complicated in that if vfo operation is desired, the 7 MHz output of the VO-1 has to be tripled, but the MX-1 cannot operate on 15m and requires a down-converter to translate 15m to 40m. Of course, the necessary circuitry can be provided and one can use the circuit of Fig. 4(B) as a tripler by changing the value of the inductor in the 2N706A collector lead. The manufacturer recommends crystal controlled TX-1 operation on 15m. A rough check indicated that the TX-1 output dropped at least 50% on 15m as compared to its 40m output.

Packaging the Modules

After experimenting with the modules on various bands, I decided to package

Front view of the complete book-size transceiver package. Controls on front (left to right) are volume with headphone sockets underneath, meter, send/receive switch, final tuning, band-spread tuning, and main tuning.

them into a truly self-contained, compact and portable single-band transceiver. I decided on 20 meters as the best compromise band for reasonable performance, portable antenna size, DX possibilities, etc. However, the construction described can certainly be applied to usage of the modules of any other band, or even for multiband usage.

The first photo shows the placement of the four basic modules in the bottom section of an 8 x 4 x 2 in. enclosure (similar to BUD CU-592). The modules are all mounted on the enclosure bottom plate with the standoff hardware provided with the modules. The VO-1 module is at top left, the MX-1 module at top right, the TX-1 module at bottom left and the AA-1 module at bottom right. The placement of the modules in this fashion was deliberately done so the low-profile modules would be to the rear. This allowed the accommodation of the battery supply in the rear upper half of the enclosure, as shown in the photos. In the first photo, you can see the main tuning capacitor (150 pF) at the upper left hand corner. This capacitor was used to replace the 430 pF variable removed from the VO-1 module. Next to it is a 25 pF variable wired in parallel to the 150 pF variable and used as bandspread tuning. The bandspread tuning was added because no reduction drive was used for the main tuning capacitor. It allows far easier tuning to be done over a narrow frequency range, especially under heavy QRM conditions. The VO-1 doubler circuit is mounted on perforated board stock immediately to the rear of the bandspread capacitor and to the left of the VO-1 inductor can. The CW monitor circuit is mounted on board stock and visible in the top center between the VO-1 and MX-1 modules. The tone and volume potentiometers are PC board types and are not brought out as front panel controls. Once adjusted, they can be left as set. Somewhat hidden behind this board is a 500 pF paper variable capacitor of the transistor radio type. It is used for peaking the 2N4427 output and is connected between ground and terminal L on the TX-1 board for 20m. Terminal E on the TX-1 board is then left unconnected. It was found not to be necessary to tune the MPS6514 stage, nor the input circuit of the MX-1 via front panel controls when operating over a 100 to 150 kHz band segment. These stages are peaked with the components already provided on their PC boards. The 200 μA meter is clearly visible and next to it is the 25 kΩ volume control with on/off switch.

The transmit/receive switching circuitry is a bit more elaborate as that previously described and is detailed in Fig. 5. The circuitry allows battery level monitoring and rf output level monitoring, as well as the usual transmit/receive transfer functions.

Operation of the transceiver on 20m has been both rewarding and challenging. There is little more to do with the transceiver in operation except to peak the front panel final tuning capacitor for maximum rf output level on the meter. A 20m dipole cut to frequency provides excellent loading.

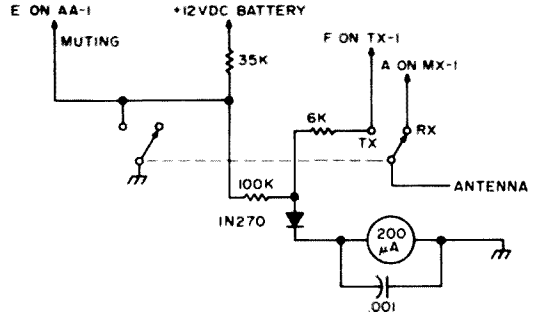

Fig. 5. A more elaborate send—receive switching circuit which provides antenna switchover, receiver muting during transmit, meter indication of battery level during receive, and meter indication of rf output level during transmit.

The operating rules for a transceiver of this power class can probably be expressed in two phrases:

1. *Never* call CQ as it is a complete waste of time.

2. When answering a CQ, wait first to hear if any strong sounding station replies also. If so, do not attempt to call the station, unless he later sends a QRZ and cannot apparently establish contact with the first station who called. The rules are simple to state and difficult to follow. But, QSOs will result instead of discarding low-power operation as a waste of time.

Further Improving Performance

The modules themselves work so nicely for their intended purpose that there inevitably follows the desire to use them as the basis for more elaborate equipment. Particularly in the case of the MX-1, there is considerable value to this idea as with some additional circuitry the MX-1 can be transformed into an excellent and inexpensive CW receiver that could rival any of the cheap-to-moderate priced receivers on the market.

Figure 6 shows an FET preamplifier stage that provides a good boost to the MX-1 sensitivity by complementing its existing low-noise FET characteristics. It is not recommended that other types of transistorized preamplifiers be used before the MX-1 since very few will have the noise characteristics necessary. Broadband, untuned amplifiers are particularly unsuitable. The circuit shown provides two additional tuned circuits before the MX-1 for added front-end selectivity. In fact, one could carry this sequence further by adding more preamplifier stages with high-Q tuned circuits in the style of the old trf receivers with 2 to 4 rf amplifier stages. One additional preamplifier stage increases the sensitivity to about 0.1 μV on CW. The circuit of Fig. 6 can function also as a mixer on 15m to down-convert 15m into the MX-1. Used in this manner, it will perform very well as a complement to the TX-1 on 15m. If one wanted to increase the 15m sensitivity further, however, an additional 3N140 amplifier stage should be used ahead of the circuit shown with 15m coils used in both the gate and drain tuned circuits. As was mentioned before, the AA-1 module provides so much gain that an additional audio filter can be used between the MX-1 and AA-1 units. A surplus FL-8 type is very suitable and L2 on MX-1 should be shorted out for this purpose. Another approach is to use a transistorized notch filter between the MX-1 and AA-1 without disturbing the audio filter on the MX-1 board.

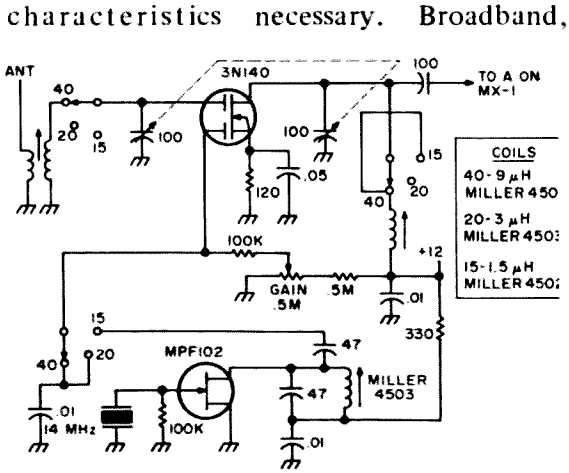

Fig. 6. Improved receiver performance can be achieved by a simple MOSFET preamp. Circuit shown can be built as a single band preamp if desired. As shown, it functions as preamp on 40 and 20m and as a down-converter to 40m for 15m input signals.

Even if one totals up the cost of the components necessary to provide preamplification, improved audio selectivity and vernier oscillator tuning for the MX-1/VO-1 combination on 80, 40, or 20 meters, it will be far less than the expense of any commercial superheterodyne receiver. However, "clean" reception due to the lack of spurious responses and the superior overload characteristics of the FET MX-1 and FET preamplifier will make reception much more enjoyable.

The TX-1 performance can be improved by the addition of another transistor PA stage. However, there is probably not too much value to increasing the power level for portable operation to the 5–20W category. Successful operation at these levels is almost 90% a question of operator techniques. The minimum power level which probably should be aimed for if one wants to boost the TX-1 level to a really useful value is 50–70W.

HAM HOSPITALITY a la LATIN

The muffled sound of the telephone bell awakened me. My hand reached out in the dark trying to locate the phone. I had just fallen asleep a few minutes earlier.

"Hello?"

"Albert, I'm sorry to wake you up at this time, but you are flying tomorrow morning to Nicaragua."

"What? What is going on in Nicaragua?"

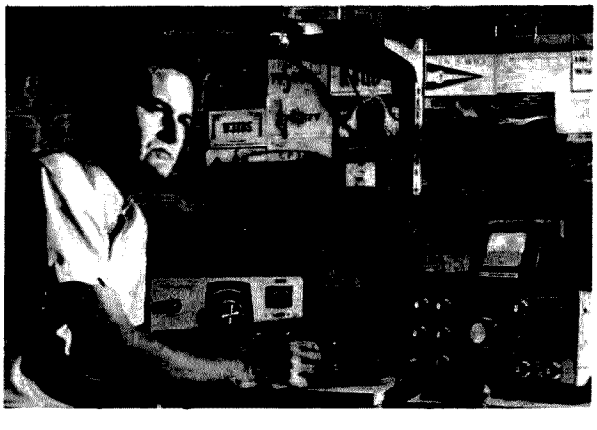
"A volcano is erupting, and we need aerial pictures of the volcano and a first-hand story on the refugees and damages."

When you are a press photographer and you work for the largest newspaper in the South of the United States, this conversation is not unusual. I am the only Spanish-speaking photographer on the staff of *The Miami Herald* so every time something is cooking in Latin America it is a good bet they will send me down there. The mud of the Puerto Rican floods was still fresh on my shoes.

"We have reservations for you at Lanica Airlines, 8:00 AM," instructed my boss' voice.

"Okay, I'll be at the airport on time."

I looked at the clock. It was midnight. I had not been in Nicaragua before, and I needed some fast information on what was going on there. My thoughts went to my ham rig lying there in the shack. Anyhow, I could not go back to sleep, and the XYL was already looking for my light suitcase.



While the coffee pot was getting hot, I went down to the shack and turned on the rig.

The familiar rushing noise came from the speaker. I tried 20 meters and to my surprise I found it was still open and a few QSOs were going on. I stopped the dial in the spot where a conversation in Spanish was in progress. After listening a few minutes, I hadn't heard any identification, so I decided to break in.

"Break, break, this is WB4SNC in Miami, looking for Nicaragua – is Nicaragua on the frequency, please?" I said in Spanish.

"A station from Miami is breaking in, Carlos . . . " said one of the voices in Spanish.

"I am looking for Nicaragua, amigo. I need some information on the volcano eruption."

W B4SNC, Albert Coya, at his shack. The equipment is a HW-101 Heathkit, a HW 32 monobander for 20 meters, and a homebrew linear. Other gear shown: homebrew phone patch, frequency counter, keyer, SWR meter, monitor scope, and power supply for both rigs.

Jaime Saenz, YN2JS, at his shack in Granada.

"Hey, Jaime, that call is for you!" another voice said.

I couldn't believe it. My first try, and there it was: a Nicaraguan station!

"Hello, this is YN2JS, in Granada, Nicaragua. The name here is Jaime Saenz. Can I help you in any way, amigo?"

"Wow! Boy, I am lucky! Jaime, this is WB4SNC, in Miami – the name is Alberto. I am a newspaperman and I have to fly to Nicaragua tomorrow morning to cover the eruption of the volcano Cerro Negro, and I need some information on what is going on. Is your city affected by the eruption?"

"Oh, no, we don't have any problems here. The volcano is in the west side of the country and the most affected city is Leon. The damages are estimated in many thousands of dollars, and the refugees are pouring out of the vicinity of Cerro Negro. At what time are you coming?"

"I am taking the 8:00 AM plane, and I will be there before noon."

"Okay, I will wait for you at the airport."

"What?"

"Do you copy me?" Jaime said, "There is no QRM in this side; I repeat – I will wait for you at the airport."

I thought I was having trouble again with my lousy dipole. I blamed myself again for not putting that quad up the previous weekend.

"Hola, this is WB4SNC in Miami, do you still copy me, Jaime?"

"Si, go ahead."

"You said you will wait for me at the airport, I believe. But, Jaime, you don't have to do that. I only need some information on the volcano, so I will know where to go from the airport. You don't have to wait for me. Of course, it will be very nice of you, and I will have the pleasure to shake your hand, but I don't want to bother you . . . YN2JS, this is WB4SNC in Miami, go."

"It is no bother at all, old man. I will wait for you at the airport, and that is final."

"Okay, Jaime, if you want it that way. Please, rent me a jeep or a four-wheel traction truck for rough terrain. Money is no problem. Probably I will have to rent a

Cleaning the streets.

plane, but there's a good chance the government will let me use military transport. I must take some aerial pictures of the volcano before we go by land in the jeep."

We said "hasta manana" with the usual courtesies, and I went to bed to grab a couple of hours of sleep.

I reached the Lanica counter at 7:00 AM.

"Sorry, senor, the plane departed five minutes ago."

"What? They told me the flight was scheduled for 8:00 AM."

"Last night's clerk made a mistake, and we are very sorry about it."

I grabbed a phone and called the editor.

"Postpone everything, Albert, maybe you'll be able to take another plane in the afternoon," he said.

I went back home. I wanted to call Jaime and tell him not to wait for me.

Again to the shack, looking at 9:00 AM for a Nicaraguan station. I have only thirty minutes to contact Jaime. After trying for ten minutes, a YL voice in Spanish answered my call.

"This is HC2NA, In Guayaquil, Ecuador, old man. I have a sked with Nicaragua in one hour, and maybe I can relay the message. The handle here is Nena."

I told Nena the story and asked her to tell Jaime to wait for me at noon on 15 meters around 21.280 kHz.

Back in the office, the editor's secretary gave me a ticket for a Pan American flight that afternoon. Things looked better then, and I went home to contact Jaime and get my suitcase.

The sked was on time and YN2JS answered my call.

"New arrival time, Jaime – I think I will be in Managua around 6:00 PM. 73, and I will see you later. Hasta luego."

"Muy bien, Alberto, I will be waiting for you."

But something was against my plans. The Pan Am flight was not direct to Nicaragua, and the first stop – San Pedro Sula, Honduras – was diverted because of bad weather, and the plane landed in Guatemala.

The last news said that the volcano was losing power, and I knew the only chance I had to take pictures of the action was flying there the next morning; not later.

Somebody up there must like me, because my prayers were answered and Pan Am sent a plane to pick up the passengers to Nicaragua.

The 707 landed in Managua at 9:45 PM, and I was worried about Jaime waiting all that time. I thought I wasn't going to find him there, but I was wrong, and a young, smiling, tall fellow extended his hand to me.

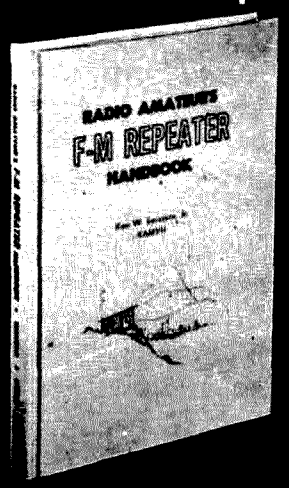
"You must be Alberto, WB4SNC . . . "

"And you are Jaime, YN2JS . . . "

We shook hands. The jeep with the driver was waiting for me. This was my first test of what the international brotherhood of ham radio is.

We had a typical Nicaraguan meal, with "churrasco" (thick steaks broiled on charcoal) and country beer.

The next morning Jaime had the jeep and the driver waiting for me at the hotel, and from there we went to the military airport. After some red tape, we used a government plane and finally flew over and took pictures of the volcano. It was a very impressive spectacle!



After returning to the airport we drove the hundred miles to Leon, and started looking for refugees and signs of destruction.

The city of Leon was covered by a thick blanket of black volcanic dust. Red Cross, civic institutions, and radio operators had joined in a well-coordinated net to help the refugees.

Every time the winds blew, the microscopic dust got airborne and made us cough and sneeze. After six hours in the place I felt as though I had sinus trouble.

Talking to the refugees, I realized all the tragedy of these poor people driven from

Want to know more about Repeaters?

$6.95

Want to build a repeater? Want to improve your existing repeater?

Whether you're a newcomer or an oldtimer, you'll find "The Radio Amateur's FM Handbook" to be the most valuable repeater aid you can get.

FOR THE OLDTIMER

the Handbook tells . . .
- how to defeat desensitization
- how to calculate attenuation according to frequency spacing, antenna separation
- how to build sophisticated control systems, using ICs, timers, relays, steppers, or Touchtone
- how to build automatic logging and identification devices
- how to build automatic phone patches

FOR THE NEWCOMER

the Handbook tells . . .
- how to prepare for a repeater
- how to get a repeater site
- how to build a repeater
- how to keep a repeater on the air
- how to determine a prospective repeater's range
- how to get your repeater license

The Handbook contains 208 pages of useful, hard-to-come-by information, and it's written in an interesting, personal view by Ken W. Sessions, Jr. (K6MVH) former editor of FM Journal, now managing editor of 73.

Order from:

73, Inc.

Peterborough NH 03458

Little refugee with the dust of the volcano on her face.

their small farms with only a few belongings over their shoulders.

We went back to Managua after visiting places accessible only by jeep. Jaime insisted that I check out of the hotel and go to his home and meet his family and friends in Granada. He lives in a palatial home with his parents and eight brothers and sisters. The house was very appropriate for a big family – a two-story green building, with a quad antenna one hundred feet in the air. A typical Spanish home with a central patio, and the flavor of the old country, complete with real hospitality, Latin ham style.

After dinner that night, Jaime took me to the Jockey Club to meet his friends, a group of radio amateurs alerted by him of my presence in Granada. Of course, we talked radio, and they made me feel at home, forgetting how tired and sleepy I was.

We called Miami and made a contact on 75 meters with WA4ZZG, Rafael Estevez, who ran a phone patch with my XYL at one o'clock in the morning.

This is the story of my fast trip to Nicaragua and my first contact with what really exemplifies the brotherhood of ham radio: an unwritten code of gallantry and courtesy.

GENERAL CLASS LICENSE STUDY GUIDE

Questions & Answers Part I

For a little over three years, we have been presenting a more-or-less continuous series of study courses for the General, Advanced, and Extra class licenses, which avoided the "question-and-answer" format so popular with many license courses in favor of explanation in depth of the theory behind the questions.

Content of these courses has been determined by the "study questions" made available by the FCC for would-be applicants. We refrained from using the Q&A format in the belief that it would lead toward memorization of the material rather than toward learning of the processes involved – and in a conviction that actual understanding of the theory was of far more importance to future enjoyment.

However, we recognize that some readers can comprehend the material more rapidly by a Q&A technicue than by our extended technical discussions, and also that anyone can make use of a checklist against which to test his understanding.

We must emphasize that for some questions a number of answers may be correct, and our answers do not attempt to provide all the possible correct responses. In some cases, the study questions are so phrased that no "correct" answer is possible (for instance, question 1 below). In these cases, we simply indicate the source or sources from which material satisfying the question may be obtained.

Many of our answers contain references in parentheses. These references are to installments of our previous study courses, and indicate where detailed discussion of the principles involved may be found.

The study list for each class of license is far longer and more detailed than is the actual examination. In addition, most of the questions in the actual exam are of the multiple-choice type, in which you select the right answer from several (usually five) possibilities, while those in the study list call either for direct specific answers, or for discussion. Both these differences are apparently designed to help assure that anyone who can answer all the questions on the study list accurately will have little difficulty with the actual examination.

1. Questions based on Part 97 of the Commission's rules.

This is not a specific question and so cannot be answered directly. It is intended to indicate that the actual exam will contain a number of questions dealing with permissible subbands, operating procedures, and so forth, all of which are spelled out in Part 97 of the FCC Rules and Regulations. A copy of Part 97 may be otained from the Government Printing Office, or found in some of the larger public libraries. Be sure to check the latest edition; the rules change with sufficient rapidity to make this caution necessary.

2. Of what use is a bleeder resistor in amateur equipment?

A bleeder resistor is an integral part of a power supply, and serves two primary purposes. From a technical point of view, its primary purpose is to provide a definite minimum load upon the power supply and thus improve regulation and filtering. From the viewpoint of operator safety, its primary purpose is to "bleed" off the energy stored in the filter capacitors and so prevent electrical shock. However, resistors can open-circuit without warning, so that a bleeder resistor should never be trusted when you work on a power supply; this makes the safety purpose somewhat deceptive.

3. Define skin effect. How can this phenomenon be minimized?

"Skin effect" is the tendency of radio-frequency energy to travel on the surface of a conductor rather than uniformly throughout the conductor's volume. This causes the rf resistance of a conductor to be greater than its dc resistance. The effect can be minimized by using conductors with large surface area (strips or tubes rather than solid wire), and by using "litz" wire which consists of many small strands of wire so braided that each is on the outer surface for the same percentage. (General course, Part IIB)

4. List some operating procedures which can be employed to minimize interference and congestion of the amateur bands.

Avoid excessively long transmissions, always listen before transmitting (to be certain that the frequency is not already occupied), speak clearly and distinctly to reduce the need for repeating information, and do your operating when the bands are least heavily occupied. (General course, part XII)

5. Describe the operation and usage of a cathode follower.

The cathode follower is a vacuum-tube amplifier circuit in which the plate is grounded (so far as signals are concerned) and output is taken from the cathode. As the grid voltage is varied by the input signal, current through the tube also varies. The current variation appears as voltage variation across the cathode resistor. This variation in cathode voltage opposes the change in grid voltage, producing very high input impedance for the circuit and a voltage gain always smaller than 1. High current is available, however, and the high current and low voltage of the output result in low output impedance. The cathode follower is frequently used as an impedance transformer or "isolation" circuit because its high input impedance imposes little load on the driving circuit, and its low output impedance makes it relatively insensitive to loading by the circuit which it drives. (General course, part V)

6. How does frequency tolerance affect band edge operation?

The existence of a "tolerance" implies possible errors, and in order to be certain that one is operating whtin the limits of a band it is necessary to add the maximum possible error permitted by frequency tolerance to the supposed frequency, when at the upper band limit, or subtract the maximum possible error, at the lower band limit. If this is not done, the error may put your actual signal outside the band limit, which is illegal. (General course, part VIII)

7. What is impedance matching and why is it important?

Impedance matching is the name given to the process of assuring that each of two separate components in a signal chain is operating under the conditions for which it was designed. These conditions are normally specified in terms of "impedance"; and when impedances are matched, power transfer is most efficient. In ham parlance, "impedance matching" is usually applied to discussions of matching antennas with feedlines and feedlines with transmitters. In this case, an approximate match is necessary to achieve satisfactory power transfer or "loading" and to minimize undesired radiation by the feedline. (General course, parts IV and XI)

8. How is the plate circuit efficiency of a vacuum tube determined?

Divide the measured signal power output of the tube by the measured dc power input. The result will always be a fraction smaller than 1. It is normally expressed as a percentage. (General course, part V)

9. What is amplitude modulation (AM)? How is the intelligence conveyed in an AM signal?

Amplitude modulation is a technique for conveying information by varying the amplitude or strength of the transmitted signal. It is the most commonly employed form of telephone communication. In AM, the intelligence is conveyed in a pair of symmetrical sidebands, one on each side of the carrier wave. The sideband energy mixes with the constant energy of the carrier wave to vary the amplitude of the composite signal envelope. (General course, part IX)

10. What is meant by the ripple frequency of an ac power supply voltage?

"Ripple" in the output of an ac-operated power supply refers to the alternating component which remains in the dc output after filtering. "Ripple frequency" is the rate at which the ripple alternates. Ripple frequency is related to the frequency of the ac input power. With half-wave rectification, ripple frequency and input frequency are the same. With full-wave, ripple is at twice the input frequency. (General course, part VII)

11. What is a third party agreement?

International regulations, to which this nation is a party, absolutely forbid international transmission of messages between amateur radio stations on behalf of any person except the two operators involved. Such messages are known as "third party" traffic. The regulations permit the rule to be suspended by special agreement between the two nations involved, however, and such a special agreement is known as a third party agreement. The U.S. has third party agreements with a number of other nations (but not all), and third party traffic may be handled with those nations. (General course, part XII)

12. How does a zener diode operate and of what use is it in amateur equipment?

A zener diode operates by means of the "zener effect" in specially constructed semiconductor junctions, which maintains a constant voltage drop across the junction regardless of the current through it (so long as the device is not burned out by excessive current). The zener diode is used as a voltage regulator, and as a source of reference voltage for electronic regulator circuits. (General course, part VII)

13. Define standing wave ratio (SWR). How can the SWR of a line be determined? How are the SWR of a line and its characteristic impedance related? Name some factors that affect the characteristic impedance of an air-insulated parallel-conductor transmission line.

Voltage standing wave ratio, to give it its correct name, is defined as the ratio of maximum voltage to minimum voltage along a feedline or other conductor which is supporting a standing wave of rf energy.

The swr of a line can be determined by measuring rf voltage along the line, determining maximum and minimum readings, and dividing the smaller into the larger. Alternatively, it may be determined by doing the same with current rather than voltage measurements. Commercial "swr meters" usually measure forward and reflected components of power, and convert the resulting "reflection coefficient" into "swr" by means of their calibration.

The swr of a line is not directly related to its characteristic impedance, but is directly related to the ratio between the impedance of the line and of the load. Swr is equal to the ratio of these impedances. Additionally, swr modifies effective line impedance between limits determined by multiplying line impedance by swr to obtain the upper limit, and dividing by swr for the lower limit.

Factors affecting the characteristic impedance of an air-insulated parallel-conductor transmission line are the spacing between conductors and the conductor diameters. A less important factor is the dielectric constant of the air, nominally 1 but varying with humidity and temperature from day to day. (General course, part XI)

14. What is meant by the maximum plate dissipation of a vacuum tube?

The maximum plate dissipation of a vacuum tube is a rating, normally given in watts, of the amount of heat which the tube's structure can withstand. It is the difference between the dc input power and the output signal power when the tube is dissipating all the power which it is capable

of converting into heat. (General course, part V)

15. What is a decibel?

A decibel is one-tenth of a bel. The bel is the unit of power *ratio*. A power ratio of one bel means that one power level under consideration is ten times the other, regardless of the actual level. The bel is the logarithm of the actual power ratio, so that 2 bels represent a 100-to-1 ratio, 3 bels a 1000-to-1 ratio, and so forth. (General course, part III)

16. What is a harmonic? List ways of minimizing harmonic generation in frequency doublers, vacuum tube amplifiers, transmission lines, and antennas.

A harmonic is an rf signal at two, three, four, or some other whole multiple, times the frequency of the original or "fundamental frequency" signal. Harmonics are generated only in non-linear circuits, and may be minimized by avoiding non-linearity where possible.

The purpose of a frequency doubler is to generate the second harmonic of its input signal. However, odd harmonics may be minimized by use of a push-push circuit.

Harmonics cannot be generated by transmission lines or antennas unless corroded joints are present to introduce non-linearities. Keeping the antenna system in good physical condition, therefore, will prevent harmonic generation there. (General course, part III)

17. What is a crystal resonator?

A crystal resonator, more frequently called simply a crystal, is a thin slice from a quartz crystal used to determine the frequency of an rf oscillator by means of mechanical resonance. Frequency is determined by the shape and size of the crystal. (General course, part VIII)

18. How do electrolytic capacitors operate and why are they widely used in power supply circuitry?

The electrolytic capacitor is composed of two plates of metallic foil, with a moist electrolyte separating them. Chemical action of the electrolyte forms an insulating compound on the surfaces of the plates. This is the dielectric of the capacitor. Because such an electrochemical dielectric can be much thinner than any conventional dielectric, electrolytic capacitors provide large values of capacitance in relatively small packages, and for this reason are widely used in power supply filter circuits. (General course, part VII)

19. What symbols does the Commission use to designate how the main carrier of a signal is modulated?

The FCC uses the alphabetic symbols "A" for amplitude modulation, "F" for frequency or phase modulation, and "P" for pulse modulation, together with numeric suffixes: "0" indicates absence of any modulation, "1" indicates telegraphy without accompanying audio modulation, "2" indicates telegraphy by the keying of a modulating audio frequency or by keying a modulated signal, "3" indicates telephone (voice) signals, "3a" indicates SSB, "3b" indicates two independent sidebands (NOT DSB), "4" indicates facsimile signals, "5" indicates video signals, and "9" indicates signals not classifiable under the remaining codes. Thus "A1" is on-off keying of an unmodulated carrier, "A3" is AM voice, "F1" is frequency-shift keying of an unmodulated carrier, and "F3" is FM voice. "A0", "F0", and "P0" all indicate unmodulated signals, but "A0" is usually used in preference to the other two.

20. What are some possible causes of excessive plate current in a class C power amplifier?

Some of the possible causes of excessive plate current in a class C amplifier are (1) mistuning of output circuit, (2) excessive coupling between output circuit and load, (3) loss of drive (if self-biased) or loss of grid bias voltage (if externally biased), (4) excessive operating voltages on plate, screen, or both, and (5) gassy tube in amplifier. (General course, part VI)

21. List several characteristics of a vertical quarter-wavelength antenna.

If operated against actual ground or an effective ground plane, the vertical quarter-wave antenna has a feed-point impedance of approximately 37Ω and a low vertical angle of radiation. The low angle of radiation makes this antenna effective for skip signals at maximum range, and in the VHF bands, prevents loss of energy at unusably high angles. The horizontal directional pat-

tern is omnidirectional. Radiation from this antenna is vertically polarized. Finally, the quarter-wave antenna is the shortest conductor which can be used as a resonant antenna; any shorter structures must be loaded to an electrical quarter-wave in order to achieve resonance. (General course, part XI)

22. What is TVI? How can it be remedied if the amateur station is at fault? If the TV receiver is at fault?

"TVI" stands for "television interference," or interference to television reception caused by radio signals. Any radio signals may cause TVI; hams are not the only offenders. If the amateur station is at fault, TVI may be reduced by assuring that no rf energy escapes from the amateur station except within ham bands. This is accomplished by shielding and filtering equipment, and by proper adjustment of the transmitter and antenna. When the amateur station is emitting no energy except in assigned amateur bands, any remaining TVI must be due to faults in the TV receiver. Not all these can be overcome, but in general, installation of a high-pass filter in the TV antenna feedline to reject amateur signals, together with (if necessary) tuned traps to specifically reject signals from the interfering station, may reduce the problem. (General course, part XII)

23. How can transistors be used in electronic equipment? What is the beta of a transistor? Compare the elements of a transistor to a vacuum tube's.

With notable exceptions due to power limitations, transistors may be used in electronic equipment in almost any place that a triode vacuum tube can be used. The major exception is that transistors are not yet capable of handling both high frequency and high power simultaneously, although they can outperform tubes both at high power with low frequencies, and at high frequencies with low power.

The beta of a transistor is its dc current gain, measured as the change in collector current for a specific change in base current with both base-emitter and collector-emitter voltages held constant, in the common-emitter configuration.

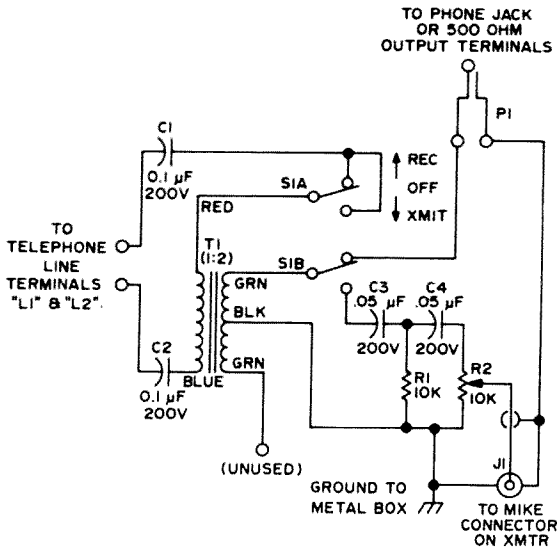
The emitter of a transistor corresponds to the cathode of a vacuum tube, the base to the grid, and the collector to the plate. (General course, part IV)

24. What is meant by percentage of modulation? What is the maximum legal limit to which an amateur transmitter can be modulated?

The modulation percentage of any transmitter, AM or FM, is defined as 200 times its modulation index. The modulation index is defined differently for AM and for FM. With AM, modulation index is defined as the peak amplitude of the modulating signal, divided by the amplitude of the unmodulated carrier, and is usually calculated by dividing the difference between "crest" and "trough" levels of the output signal by the sum of "crest" plus "trough" to produce a fraction between 0 and 1. For FM, modulation index is equal to maximum deviation divided by maximum modulation frequency. In all cases, amateur signals are limited to a maximum of 100% modulation. (General course, part IX)

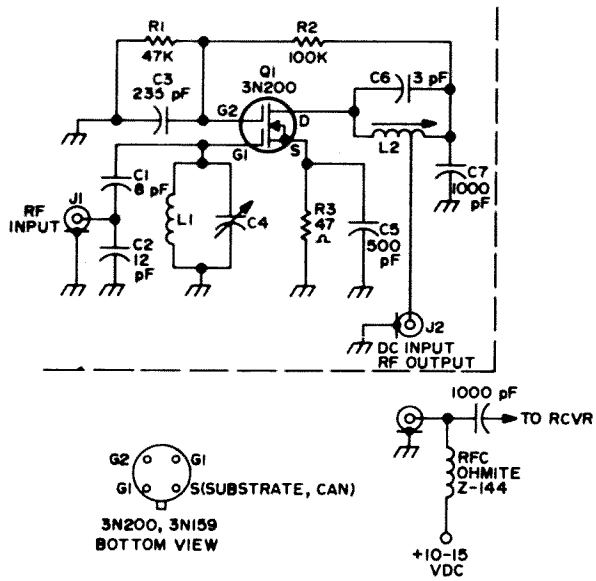
25. Describe briefly how oscillators operate. What are the most common types of oscillators and how do they differ from each other?

Oscillators generally consist of an amplifier, a resonator, and a feedback circuit so arranged that output of the amplifier is returned to its input in the proper phase to provide adequate input level and maintain maximum output. Any of these components can be varied to produce a different type of oscillator. Some common oscillator types are the Hartley, which has its feedback network connected in the cathode circuit through a tapped coil; the Colpitts, which employs a capacitive voltage divider for its feedback network; and the Armstrong, whose feedback network is in the plate circuit. (General course, part VIII)



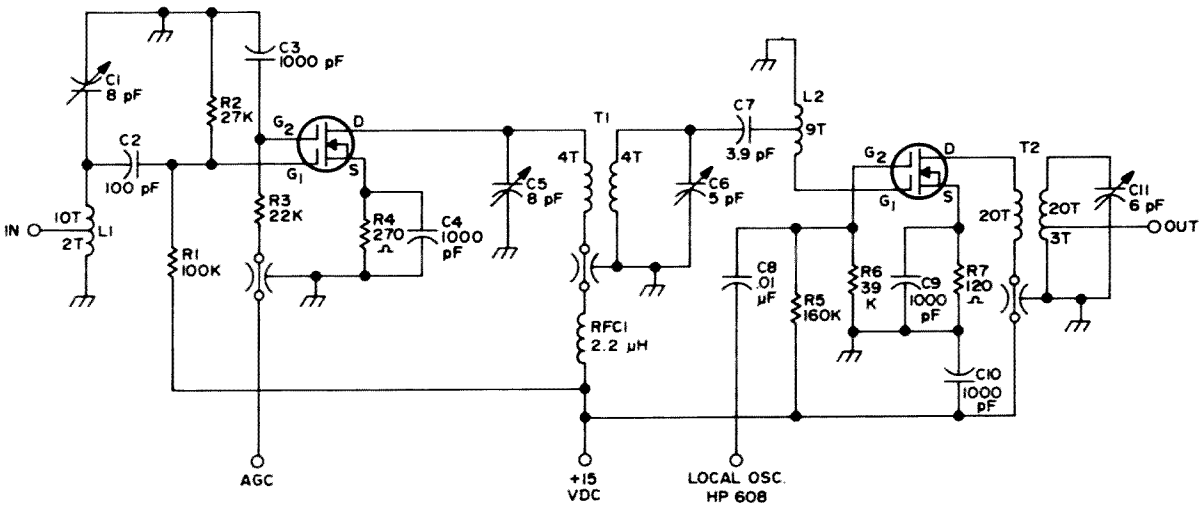
26. Why is a centertap return connection employed on the secondary of a transmitting tube's filament transformer?

To prevent or at least reduce amplitude modulation of the output signal by the ac voltage applied to the filament. (General course, part VII) . . .Staff

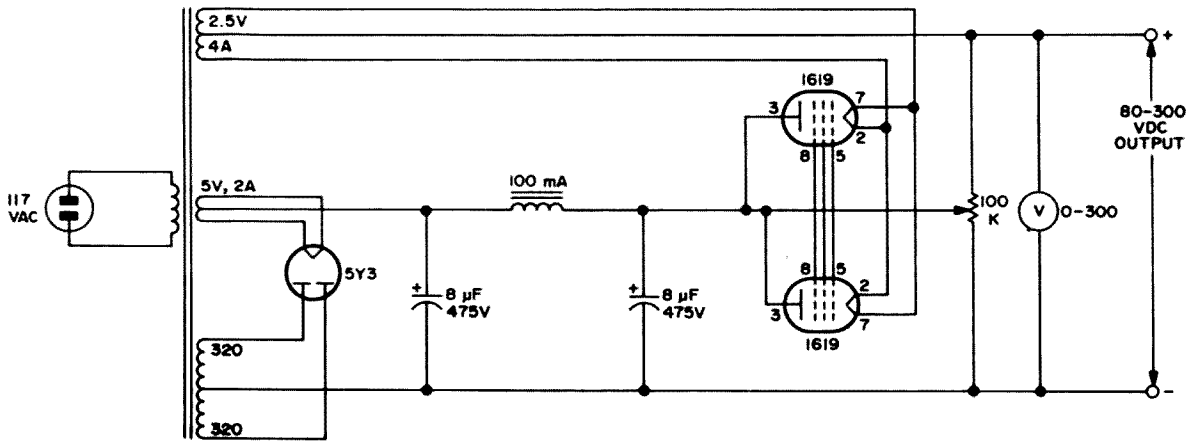


CIRCUITS, CIRCUITS, CIRCUITS...

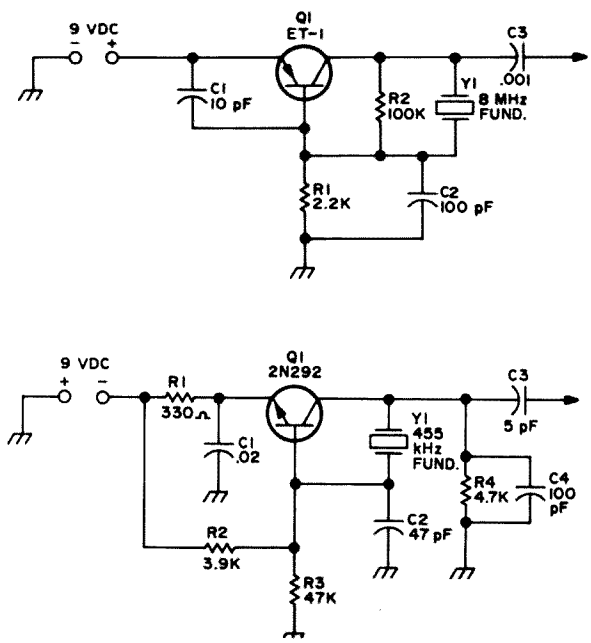
The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.



Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.



A simple and efficient phone patch, by Herbert S. Brier W9EGQ, from an article by that title in the December 1960 issue of 73. Still as simple and efficient as ever!



Two meter preamplifier, MOSFET. C4-5 are button micas and support transistor leads forming resonant circuit. L1 is JFD LC374 tank circuit which contains C1. HEATHKIT MODIFIED HW-16

CW TRANSCEIVER

John N. Edgerton WA3PRV
129 Robinson Drive
New Castle DE 19720

Having built two Heath kit HW-16 CW transceivers for friends and hearing such successful reports, I decided to purchase one myself. I ordered the kit and, while it was enroute, borrowed a manual for the HW-16 from a friend.

After studying the manual and evaluating performance standards, I decided to make a few refinements. Upon its arrival, I had an outline of modifications as shown below.

- Change final tuning.
- Add variable antenna load instead of fixed load.
- Add variable selectivity.
- Add fine tuning.
- Improve transmit oscillator.
- Incorporate constructional refinements.

The fine tuning feature came as an afterthought. Because of the variable selectivity, I needed to retune my present receiver after changing from one selectivity position to another. The fine tuning also helps tune more accurately if the band is crowded.

Change Final Tune

I found that on 3.7 MHz, the HW-16 would not tune to a peak; that is, the plate tune capacitor (C28) would have to be turned to its extreme clockwise (open) position to get good output. I reduced the capacitance by changing C27 (150 pF, 4 kV capacitor) to a 100 pF, 4 kV capacitor, as shown in Fig. 1.

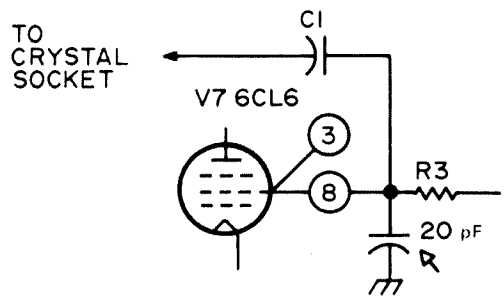

Fig. 1. Substituting a 100 pF capacitor in place of the original 150 pF value will extend the HW-16's tuning range.

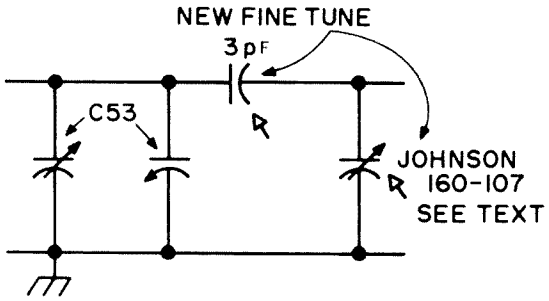

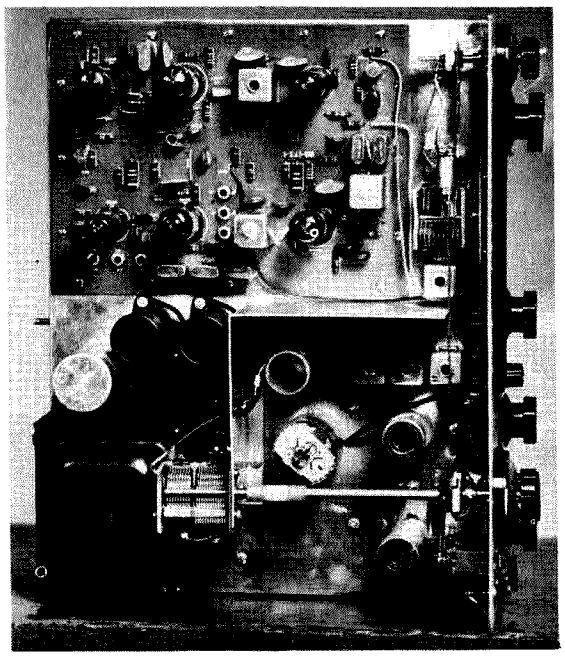

Fig. 2. A 365 pF variable from a BC radio is an ideal substitute for the original 390 pF fixed load, and allows a wide degree of antenna load adjustment.

Antenna Load Control

The HW-16 comes with fixed load on all bands. Capacitors C29, C30, and C32 comprise the loading on the HW-16 antenna circuit.

A 365 pF variable from a BC set improves the antenna loading, but it involved moving the panel meter to accommodate the vernier control.

I removed C32 (390 pF) and mounted a 10–365 pF variable capacitor above the chassis near the power transformer as shown in Fig. 2. The 10–365 pF capacitor, from a 5-tube table model BC set, improves the load to the antenna. I had to move the meter as shown in the lead photo. I also mounted a vernier dial to the panel and used a flex coupling and a plastic half flat coupling to get back to the antenna load capacitor. The center conductor of the RG-58 I used for hook-up is connected to both sets of stationary plates; the other end goes to the top terminal of the tank coil (the shield is grounded). The fact that the new variable capacitor is 25 pF less than the original does not seem to make any difference.

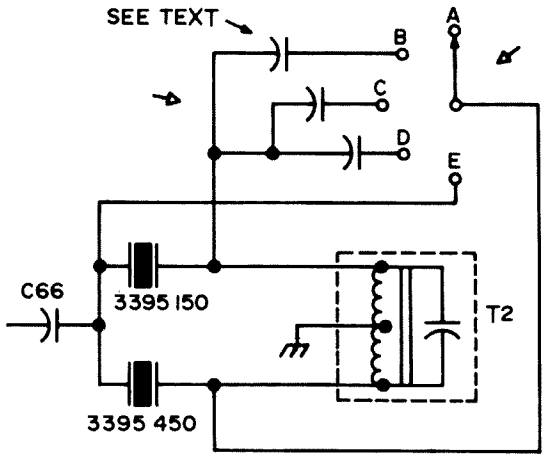

Fig. 3. A multiposition wafer switch can be used to obtain a variety of selectivity bandwidths.

Variable Selectivity

Ever try to copy CW on 40 at night? I do! Even with 500 Hz selectivity it is hard. To make this possible, I installed a 5-position selector switch at the lower right cover of the front panel. The first position (0.5 kHz selectivity) is not used (position A of Fig. 3). The second (B) puts a 15 pF capacitor across the i-f transformer. The third (C) puts a padder (which came out of my junkbox unmarked) across the i-f transformer output, and the fourth position (D) connects a .002 μF capacitor in like man-

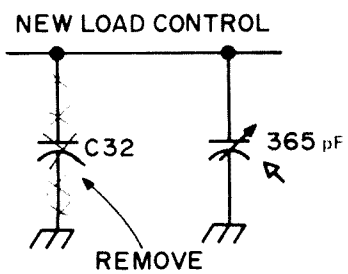

Fig. 4. A little "fine tuning" capacitor compensates for vfo shift resulting from selectivity switching.

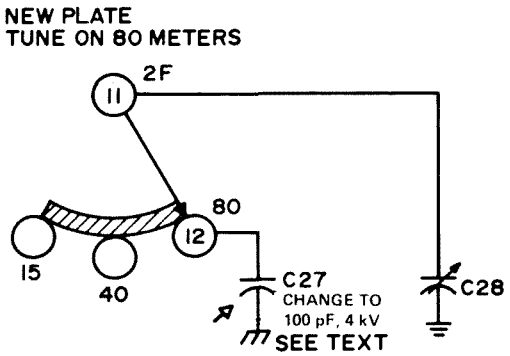
ner. Position E puts a shunt across the 3395.150 kHz crystal, allowing me to copy a very weak station when the band is quiet. I can also copy the upper 50 kHz of 40m sideband.

Fine Tuning

I found that by switching selectivity, the receiver calibration would vary a little. I installed a Johnson 160-107 capacitor (bolted to a bracket on the pilot light support behind the main dial), and connected it as shown in Fig. 4. It is driven by a small vernier dial. The capacitor connecting the vfo capacitor (C53) and the new fine tuning capacitor is a 15 pF ceramic. I had to realign my vfo a bit after the above modification.



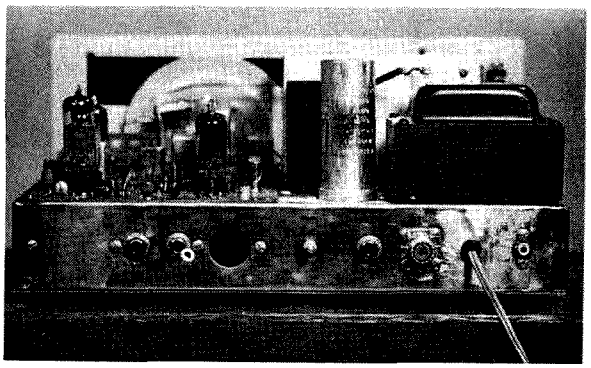


Fig. 5. A 20 pF capacitor on the HW-16 oscillator cured the problem of occasional inoperation.

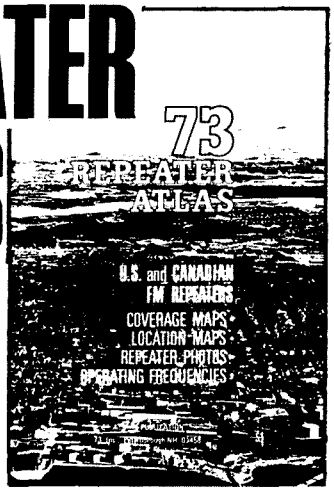

The chassis corners are darkened from brazing that was done to make the chassis sturdier.

Crystal Oscillator Improvement

Periodically, the HW-16 rigs have been known to fail to oscillate when the key is closed. Occasionally it would also hesitate long enough to make a very short "dit." To

NEW! REPEATER ATLAS

Maps showing the area covered by most of the repeaters.
An up-to-date listing of the open repeaters nationwide.

This is the book to have for your glove compartment in your car. When you are travelling now you will know what channels to use to get into the repeaters. Say you are driving along the New York Thruway . . . what repeaters can you use and over what range? Check the ATLAS.

Perhaps you are flying into Chicago for a business trip or convention . . . what repeaters can you use with the little rig you plugged into the rented car? Check the ATLAS!

Or are you just getting the FM bug and wondering whether there is a repeater which covers your town? Check the ATLAS.

Going on a vacation and want to route yourself through as many repeaters as possible? Check the repeater ATLAS.

Is your repeater group thinking of changing frequencies? Check the ATLAS!

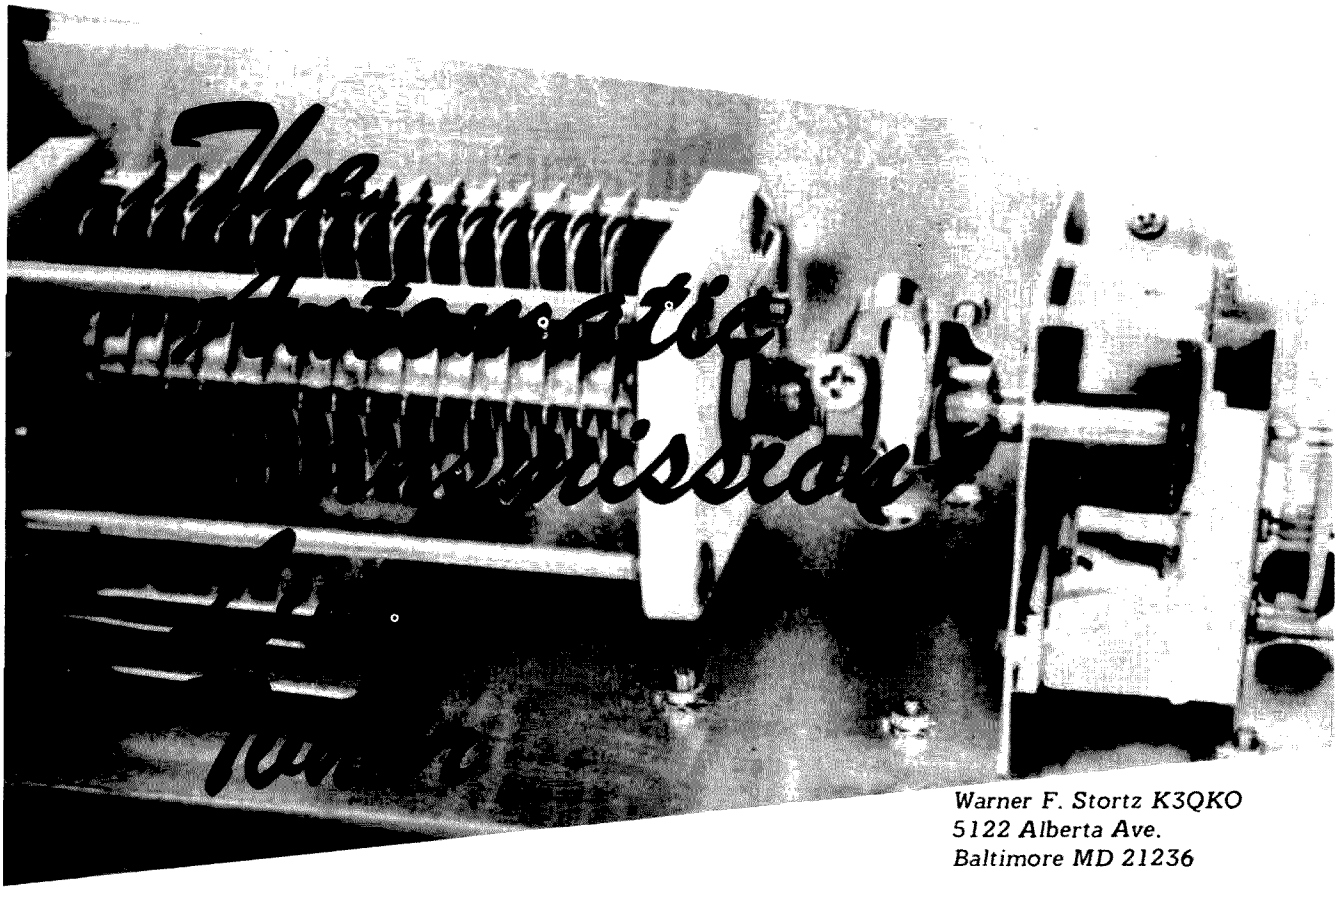
Heavy wires between the shield and the bandswitch help to maintain a solid ground and also serve to add support to the switch.

overcome this, I put a 20 pF mica between pin 8 of V7 and ground (Fig. 5). No more oscillator malfunction!

Constructional Refinements



If you look at the chassis photo, you will notice the corners are darkened. This is from brazing to stiffen the chassis . . . and it works. I cut out the antenna connector hole to 5/8 in. and installed an SO-239 coax connector. I also changed the speaker jack to a standard phone jack. I bolted all terminal strips and tube sockets in place, and with a 300W soldering iron, I re-soldered all ground lugs and did the same with the C204 metal wafer plate.

I found that supporting the bandswitch at the rear made it much sturdier. I silver-soldered a brass nut to the chassis between C202 and C203 in line with the bandswitch and filed a small groove in the nut to support the bandswitch exactly parallel to the chassis. At final assembly, I soldered the bandswitch to the brass nut.

In the underchassis photo, you will notice extra ground wires soldered between the bandswitch and the shields. They also help to sturdy the bandswitch.

I wish to express my gratitude to Mel (W3KET), who helped me a great deal with technical advice – also to Donaghey Brown, a photographer with the News-Journal Co., Wilmington, Delaware, who did the photo work for this article.

Baltimore MD 21236

Reducing aggravations around the shack is a job that keeps the average homebrewer happily scheming and building throughout his hamming life. At the top of the "bother" list is the matchbox that must be readjusted after you make a large frequency change within a band, and the box is located on the other side of the power lines, in your garden tool shed. Anyone that has put up with this problem for years, must have wondered as I did, if you could tell your hand which way to turn the knob on the matchbox by watching the vswr meter, why can not the signal that deflects the meter do the job for you.

While working on the problem of getting the meter to twist the knob, it was soon discovered that the mismatch defying adjustment at the transmitter is the one that causes a reactive current to appear at the load end of the transmission line. A resistive mismatch as large as 3:1 causes little fuss and can be tuned out with ease. For this reason, the change in the resistive load presented by the same antenna at different locations in a given band is not large enough to require an adjustment, so one setting of the matchbox input loading capacitor is good for the entire band. This is not true of the output capacitor. It must be reset to bring the antenna–transmission line combination back into resonance, or a large inductive or capacitive phased current will be reflected back to the transmitter along the coaxial cable. It then follows that only one shaft requires adjustment after a frequency change is made, and if any change in the phase relationship of the current to the voltage in the coaxial cable at its load end could be detected and converted into a dc voltage, this signal could become the start of the automatic control that we are looking for. Such phase changes can be detected and converted into rotary motion!

The automatic transmission line tuner, whose name we will shorten to ATLT, is designed as an outboard unit to work in conjunction with a simple matchbox of the fundamental type described in most handbooks. Figure 1 shows how it is used in a typical antenna feed system. The matchbox consists of a small input coil that has a

loading capacitor in series with it and ground, inductively coupled to a large parallel-tuned coil which has the balanced transmission line fastened to it by means of taps. The ATLT uses a variable capacitor connected across the matchbox output to make any corrections that might be required to maintain resonance as the transmitter frequency is varied. It will maintain the coaxial cable vswr to better than 2:1 and will operate in the 80, 40, 20, and 15m bands. Transmitter inputs can be as small as 90W, or as high as its variable capacitor will handle. The highest power used during tests was 800W, the top input of my rig. The unit is battery powered and the design is such that no current of a magnitude that can be detected on a 50 μA meter will flow without the presence of an rf signal. This feature allows unattended operation in remote locations with battery life going into months. The servomechanism is not made in a machine shop. It came out of a battery-powered toy automobile and works like a million dollars instead of two.

The way the ATLT circuits work could be called clever, but never complicated. There is an element designed to pick up the coaxial cable current (L1, Fig. 2) and transform it into a useful signal that can be summed with the cable voltage, much reduced in amplitude. The resultant of these two signals, detected by diodes, produces a dc voltage that is positive, negative, or zero, depending upon the phase relationship of the current to the voltage. This circuit is known as a phase-sensitive demodulator and is the ATLT nerve center.

Current coil L1 is a laterally wound coil that encircles the coaxial cable inner conductor. When the alternating current through the cable increases, decreases, and then reverses direction, an expanding and contracting magnetic field is produced, inducing a potential across this coil. This voltage is 90 degrees out of phase with the cable current because of the electrical law stating that magnitude of a voltage induced into a conductor by an electromagnetic field is directly proportional to the rate of change of this field. When the current, alternating from its peak negative to its peak positive value passes through the zero point, the rate of change is at its maximum and is displaced by 90 degrees from either current peak.

Without the voltage signal present, the rectified currents out of the ends of L1, through CR1 and R2, CR2 and R1, and back to its centertap, will be equal in each circuit branch. This produces a zero potential difference across the R1-R2 divider. The primary voltage signal path is through R3, to the centertap of L1 and out its ends, through CR1 and CR2 to ground. C1 provides an ac ground to both ends of the R1-R2 divider, plus smooths the pulsating dc. The secondary path through R4, R5, and C2 reduces the voltage applied to L1 and allows small phase corrections to be made to it. When the voltage signal is present, it will add to or subtract from the current signal, depending upon their phase relationship. If the voltage and current signals are directly in phase, then across one coil of L1 they will add while across the other they will subtract. Unequal currents will flow through R1 and R2 creating a potential difference across the divider. If the phase is changed 180 degrees, this potential will be of the same magnitude but of opposite polarity. When the signals are phased 90 degrees to each other, right in the center between 0 and 180 degrees, equal currents again flow and there is no potential difference. The voltage signal, applied to this phase-sensitive demodulator, is not shifted from its original phase, while the current produces a signal that is shifted 90 degrees. Therefore, when the coaxial cable voltage and current are in phase (unity power factor) there will be no demodulator output measurable across J3 and J4. Any small change in this phase relationship will result in an output that will be either positive or negative, depending upon whether the angular difference is leading or lagging.

The demodulator output is applied between the base and the emitter of Q1 and Q2. Q1, being an NPN transistor, will be switched on when the output is positive, and Q2, a PNP, will turn on when it is negative. Both transistors are operating class C and require about 0.5V of signal

before either will conduct. Q1 and Q2 are direct coupled to Q3 and Q4. Either one or the other can be switched on, actuating K1 or K2, depending upon the state of the demodulator output. K1 and K2 are high-resistance, low-coil current relays with their contacts wired so that a high-current positive or negative, 3V dc output is made available to operate the servo motor, which positions variable capacitor C4. C4 is connected across the matchbox output and will automatically be repositioned every time the power factor in the coaxial cable changes from unity, bringing the antenna system back into resonance.

The reversing switch (S2) is used to eliminate the construction problems that would be brought about by trying to keep all phases and outputs aligned so that the servo motor will turn in the correct direction when called on to make an adjustment of C4. A complicated switch of this type is not needed if C4 does not have stops and will rotate 360 degrees. This is because C4 can be turned in either direction to its correct location.

A homemade fixed capacitor (C5) is used during 15m operation to prevent "hunting." Hunting is the oscillating motion of the servomechanism about null that takes place when variable capacitor C4 coasts through the null point after the motor power drops to zero, causing the demodulator to produce an output that drives the motor in the opposite direction, where it coasts past null again repeating the whole process. Series connected C5 makes it necessary for C4 to move a reasonable number of degrees to make an effective adjustment.

The ATLT is assembled on a 2 in. chassis of about 5 by 7 in. area. The front and rear panels are across the narrow ends of the chassis and are 5 in. high with rounded corners. The cover is a wrap-around type that snaps in place by holes in its lower side picking up the protruding heads of screws mounted in the chassis. Easy cover removal is necessary unless some sort of dial is provided to indicate the rotor position of capacitor C5. The front panel controls are: *phase* potentiometer R4; *amp* and *servo* switches S1 and S2; *demod* and *sig gnd* jacks J3 and J4.

Connections to the fixed and variable capacitors (C5 and C4) are brought through the rear panel using high-voltage ceramic feedthrough insulator posts. A shield, run down the center of the chassis, provides a place to mount the battery holders. The one for the 9V batteries is made of thin aluminum, while the 1.5V cells are held in the battery box removed from the toy auto which also provided the necessary motor gearbox assembly.

The current pickup coil details can be seen on Fig. 3. A piece of RG-8/U coaxial cable is cut so that it is long enough to be

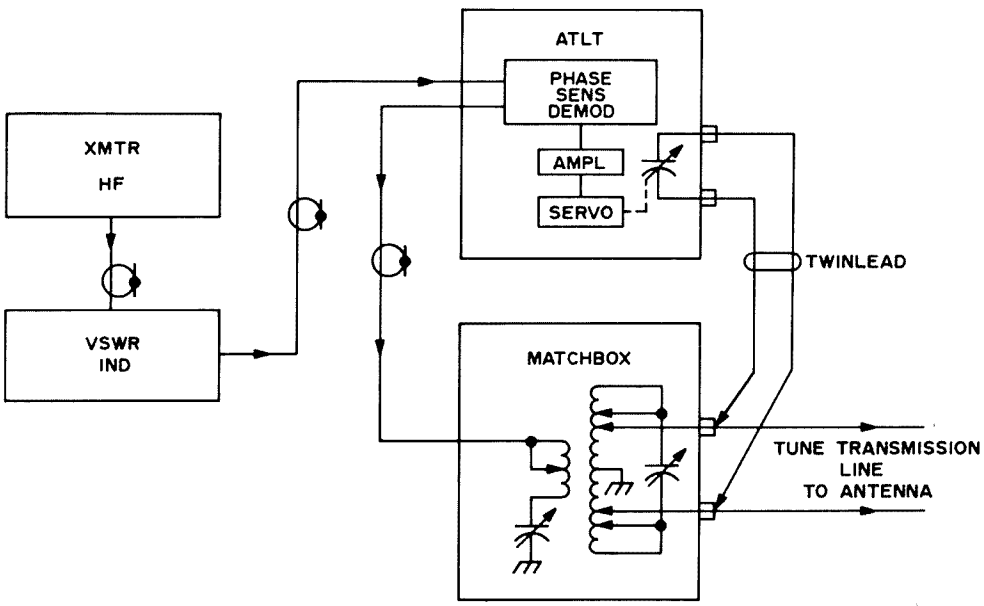

Fig. 1. Block diagram.

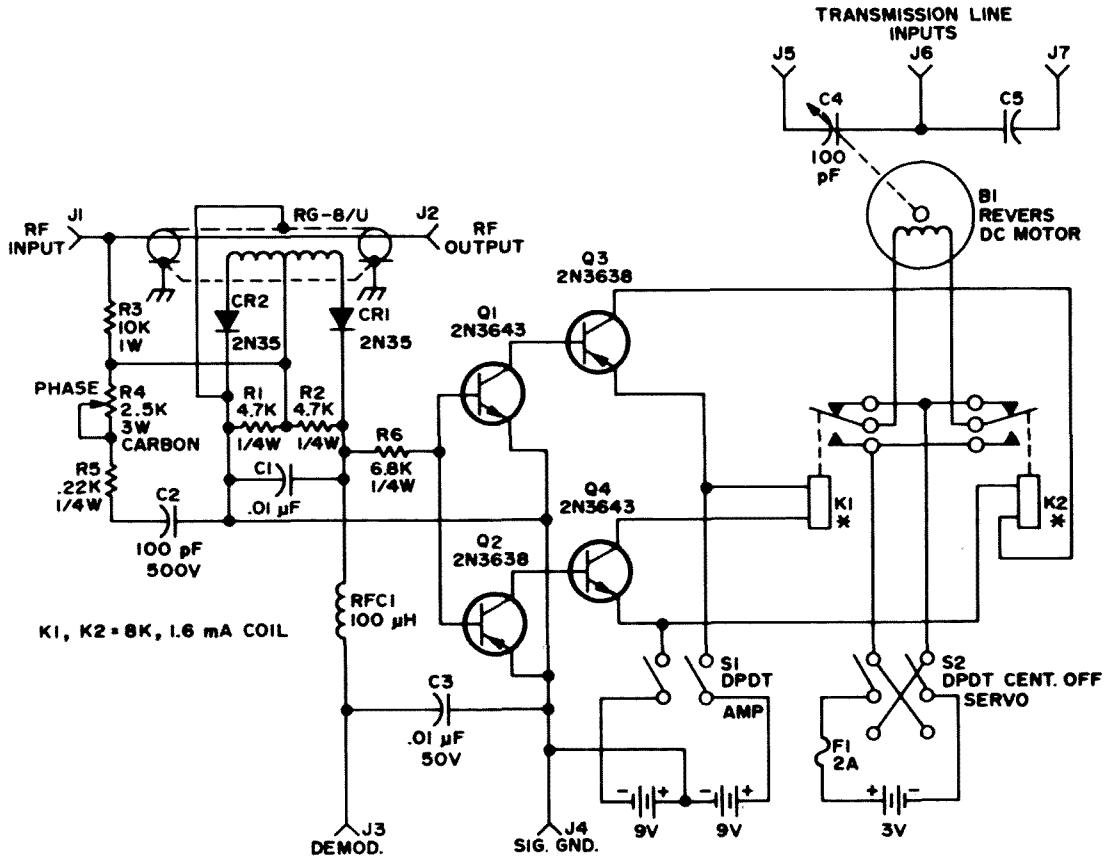

Fig. 2. Schematic — ATLT Unit

soldered between box connectors J1 and J2, located either side of the chassis at the back. The outer insulating jacket is slit lengthwise and peeled off in one undamaged piece, because it will be used for a form for L1. The braid is also pushed off undamaged so it can be later replaced. The outer jacket insulating material is wrapped around the insulated center conductor and trimmed so that it will fit snugly without overlapping. Its length is trimmed to 2 in. and a hole is punched in its end either side of the slit for the coil leads to pass through. Seventeen bifilar turns of 28-gage enamel wire are wrapped around the jacket material lengthwise. (Seventeen bifilar turns are equal to thirty-four single turns.) The start of coil B and the end of coil A are twisted together. These leads will make the centertap when they are soldered. The other leads, along with the centertap, are slipped into an insulating tube, and the completed L1 is thinly taped around the insulated coax center conductor. The braid is expanded and slipped back over L1 and the center conductor, fishing the L1 leads out through a hole worked into it about ¾ in. from one end. The whole thing now looks like a short piece of RG-8/U without its outer jacket, and a small lump where L1 is located under the braid. The tubing, with the L1 leads in it, will be coming through the braid at one end of this lump, and when the current pickup assembly is soldered to the box connectors, this end will be near J2. The braid ends are wrapped and soldered to one turn of bare wire, and these wires are connected to two ground lugs at each connector shell.

Constructing a servomechanism turns out to be a lot less frightening than first thoughts make it seem. In fact, it is quite a satisfying experience using the old Yankee know-how to get the machine to run. Timer assemblies make excellent servomechanisms for this application, but require power sources not readily portable. Luckily, battery-powered motor-gearbox assemblies abound in any toy store. There are more snappy battery toys made today than one who has been away from such things has a right to realize.

There is no reason for not being selective about picking out a toy that operates

rather slowly, and has an easy to-get-at drive assembly. I settled for a model of a Ford Mustang. The complete title on its box is "*Non-Fall Mystery Bump'n Go Ford Mustang GT-41*". It is an all-metal model, and runs relatively slow to the edge of a table and then, before dropping off to the floor, it turns itself around and proceeds back over the table again as if it had eyes.

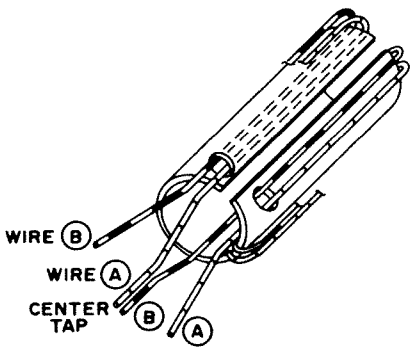
The metal construction makes it easy to take apart, because it is held together with metal tabs bent over here and there. The motor and gearbox, along with the rubber drive wheel, comes out in one piece after straightening a few tabs. It will require minor modification before a ¼ in. shaft can be mounted to it.

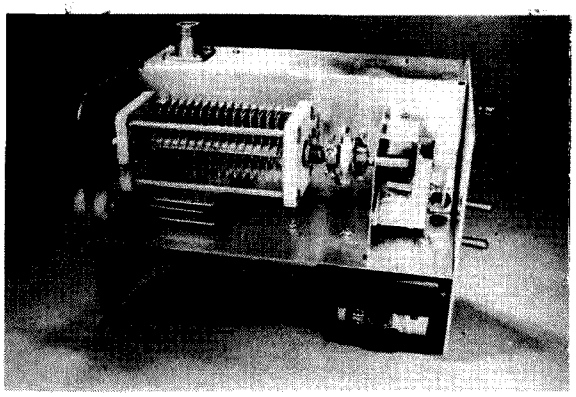
The electronics is built on a perforated Vector board and arranged to look neat. The transistor types can be changed to practically any silicon NPN and PNP type and still work fine. The balanced 2N35 diodes are rather old-fashioned and can be replaced by other types if you pick a pair that have equal conduction. I do not know the brand of the scrounged relays, however, they have 8 kΩ coils and will operate with 15V across them. The circuit board is mounted on spacers under the chassis and wired to the switches, jacks, L1, and signal ground (which is a point on the coax braid over the center of L1); R3 is connected to the center conductor of J1.

C5, the homemade fixed capacitor, is made from a U-shaped square (1½ in.) of aluminum. The top of the "U" end is trimmed ¾ in. deep so only the lower ½ in. of it is left. This portion is drilled and bolted to the 15m (bottom) feedthrough post. The center plate is a 1½ x 2 in. right angle shape with a ½ in. flange. The lower portion of the flange is trimmed like the "U" so it will clear the 15m feedthrough post. The tab that is left is connected to the center post that also feeds the stator of C5. The plates of the capacitor are bent until they are spaced ¼ in. from each other.

Before operating the completed ATLT, a few precautions should be taken. The plate spacing of C5 is about .070 in. This makes it necessary that the length of the tuned transmission line be selected so that a very high voltage will not wind up at the matchbox output. Remember, a quarter-wave line inverts the load connected to it, and a half-wave line will repeat it. Be careful that rf does not get into the unit from the test meter, or indications will be erratic. Check that the transistors do not have a current flow before an rf signal is present. Keep in mind that the ATLT will detect and correct *only* reactive power conditions in the coaxial cable, so the vswr indicator can be indicating a high vswr of a resistive nature that will not be seen by the ATLT. The resistive mismatch must be tuned out with the matchbox input capacitor, but only one time for each band.

After the above checks are made, connect the ATLT in series with the coaxial cable running to the matchbox input, along with a vswr indicator ahead of it. Connect C5 across the matchbox output using a short piece of TV twinlead, and set the rotor halfway open. Load the matchbox with a lamp so that its output capacitor





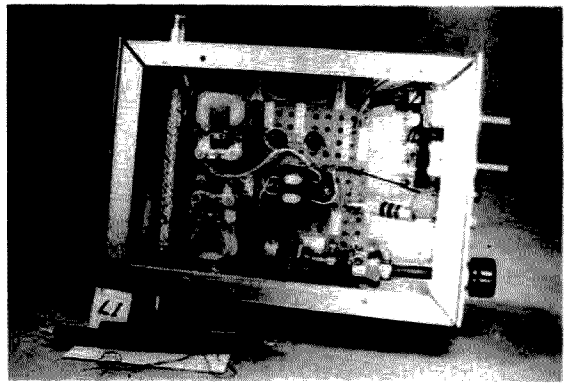


Fig. 3. L1 construction is on 2 in. long RG-8/U casing; 17 turns (lengthwise) of 28-gage enamel wire.

The automatic transmission line tuner connect to the matchbox.

The ATLT, top view.

The ATLT, bottom view.

will tune rather sharply (coil loaded to a medium Q). Set all ATLT switches off, and apply a 40 or 80m signal to the setup. Adjust the matchbox for optimum output.

Rotate *phase* control R4 to the center of its travel. Measure the demodulator output between J3 and J4 using a 20 kΩ/V meter, and readjust the *phase* control for a null indication. Move the matchbox output capacitor slightly one way and then the other from the set position and the meter will indicate a potential, a null when returned to set, and an opposite polarity potential when on the other side of set. Place the *amp* switch S1 on. K1 and K2 will click on and off as the capacitor is rotated through null.

Place the *servo* switch S2 on and the servomechanism will relocate variable capacitor C4 to compensate for these position changes. If C4 drives against one of its stops, set the *servo* switch to its other position and the motor will drive in the correct direction to produce a demodulator null. When the transmitter frequency is changed, C4 will be driven open or closed as the frequency is increased or decreased, and the vswr indicator will indicate a low ratio.

C4 is not a large capacitor and with some matchboxes it might not be capable of adjusting throughout the entire spectrum of the lower bands, but it most certainly will cover whole CW or phone portions. Try the setup on the other bands, using C5 in series with C4 on 15m. If trouble is encountered, the ATLT may be tested like a vswr indicator by connecting a dummy load to coaxial box connector J2. Under this condition the demodulator output should be less than 0.5V.

After these tests are completed, the ATLT is ready to be connected to the antenna feed system as shown in Fig. 1. It will operate just like it did during bench tests, correcting for all transmitter frequency changes large enough to cause objectionable standing waves along the coaxial cable.

This method of antenna tuning, to my knowledge, is new but as reliable as a vswr indicator. It is tuning a center-fed 33 ft antenna for me with wonderful results on all bands. (The 33 ft distance is the space between two nicely positioned trees and not meant to be some magic length that produces red hot results.)

I guess that it is obvious by now that C5 could have been a roller inductor at the base of a short vertical antenna, continuously adjusting it over the whole band, or the servomechanism could be rotating the matchbox capacitor instead of an outboard unit. What may not be obvious is that this idea can be expanded to include the automatic tuning of tank circuits by placing L1 in one of the circuit leads and shifting the voltage signal 90 degrees before it is summed with the current signal. By using varactors and motors I believe an entire transmitter could be automatically tuned. This is one of the most exciting projects I have worked on: real automatic fedback control of rf. ...K3QKO■

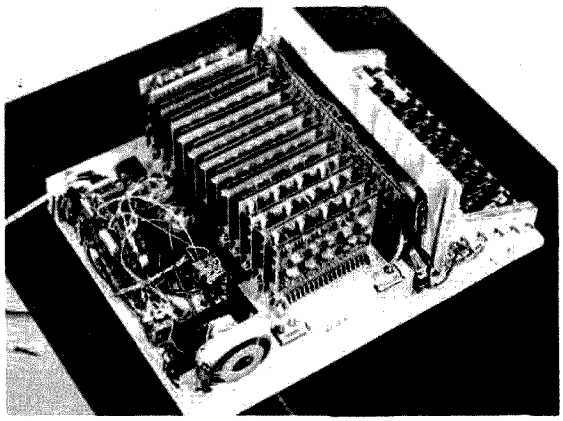
The Button Box

An automatic morse code generator driven by a keyboard for better sending by everybody

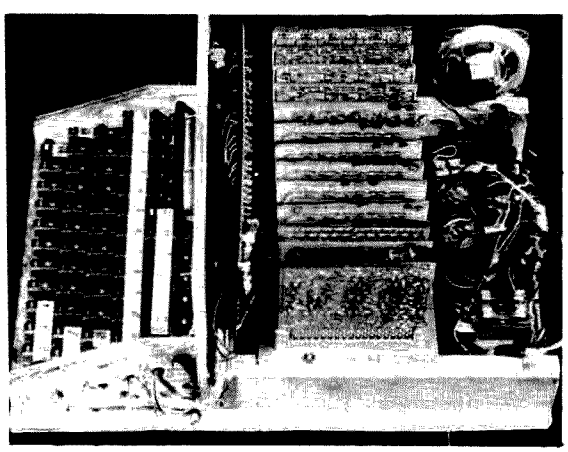
The *button box* is another version of a keyboard code generator, and discloses no new and startling techniques. In presenting the button box, I intend to introduce you to digital logic, describe the logical operations involved in generating the code, and give you some ideas for building your own. Nothing in the descriptions or drawings is sacred or critical, and were intended not for duplication but rather to arm you with enough information to combine your ideas with mine and build a unit that will fulfill *your* requirements.



THE BUTTON BOX

Keyboard articles by Horowitz (QST, Aug. '64 and Oct. '68), Granberg (CQ, Sept. '64), and Bryant (QST, July '69) are all excellent and recommended reading. Each of the keyboard units described in these articles has its advantages, and perhaps by combining portions of each, one could devise the ultimate in compactness and versatility. However, I find it difficult to use components that I do not understand well, and prefer to use old "tried and true" discrete components. By using these, I can get by without a scope (in most instances), and can measure almost any point in the logic with my voltmeter.

In dreaming up the button box, several problems confronted me: First, money was not too plentiful. The bargain ads consulted for components revealed that surplus computer cards could be bought quite reasonably and either used as-is or stripped for the components.



Secondly, I am no craftsman, and had only a few hand tools to use in building the keyboard. I used plywood to build the button box, but Masonite, aluminum, or whatever your favorite material is, could be used. The keyboard switch problem has been solved a number of ways, but I took the easy way out when I found a bargain sale on "micro" switches.

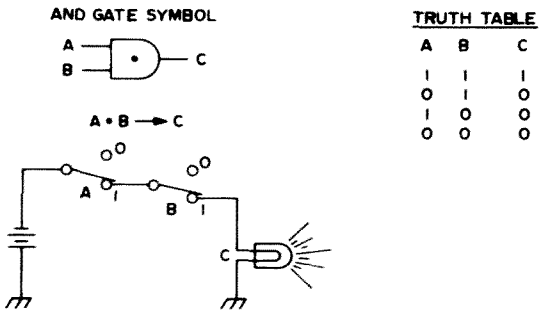
Last, but far from least, I wanted the logic to be straightforward, and the parts mounted so they would be accessible for repair or modification. I have justified this approach by making a number of changes

In this view of the button box, the discrete components are shown on their plug in PC cards. The power supply and speaker, not modular, are shown at the back of unit.

and circuit additions that I would not otherwise have been able to make. Most of the additional circuitry is for station control and does not affect the button box itself, so will not be discussed here. Each button controls an encoder gate that uniquely defines the character to be generated. This approach, although using additional diodes, simplifies the tracing of troubles in case a component becomes defective. Since the last bug was tracked down and slain in April 1968, only one problem has developed to test this theory. A transistor in an input *nand* gate proved to be sensitive to the heat of our July, and was promptly located by listening to the errors caused in the code. Verification that the culprit had been found was made using an ohmmeter, and a lighted cigarette as a spot heat source. Replacing the transistor took but a few minutes, and no troubles have developed since that time.

Detail of keyboard and wire routing method.

Advantages



Expending so much time and even a little money just to build a unit to replace the hand key hardly seems justifiable, and may appear somewhat ridiculous to the uninitiated. Even if that was the sole reason, it would be worth the effort to put better, more readable CW signals on the air, but there are other uses for the button box which have little to do with on-the-air operation.

It is great for code practice sessions, either on or off the air. The built-in monitor can be made loud enough for room use, or feed separate jacks for use with headphones. Individuals, or groups, can learn the code without any prior training or CW knowledge, because as each button is pushed, a character is generated. The sound of that character is associated with the legend inscribed on the button, so there is little chance for error. Any speed wanted can be accommodated, and double characters, repeats, or combinations can be sent without the problems associated with disk or tape recordings.

An advantage not to be overlooked, and one that is important to me, is that those of us with an infirmity or physical defect that makes it difficult to use a straight key, bug, or keyer-paddle can now send beautiful code by using only one finger if necessary. Loss of the thumb on my paddle-wielding hand curtailed my CW activity until I completed the button box. Now I get compliments on how nice my "fist" sounds, and I enjoy CW more than ever.

Who???

NNGT is often heard on the CW band. No – this is not a ship at sea operating on the wrong frequency, but is what all-too-frequently passes for CQ when the fellow sending has a really swinging fist. Or, how often do you hear NST? Of course he really means TEST, but then, everyone knows that – or do they? Poor CW is always a problem with the *other fellow* – never ourselves. With a button box you can be certain that you are not the *other fellow* but the one who actually "sounds better than tape."

Introduction to Logic

If you have read this far, you are seriously interested in building a button box, so let's review the logic elements that are used as building blocks and dispel the aura of mystery that seems to surround these computer circuits.

In the discussion of a specific circuit design, it is necessary to define logic levels in terms of voltage. However, when using logic symbols and describing logical operations, only two conditions concern us: (1) either a statement is true; (2) or a statement is false. The binary system consists of only two states, and is regularly applied in daily life. For instance, a light bulb is either on or off, it is day or night, or a door is open or closed. "The light is on" is a statement of fact, and we can assign a symbol such as **A** to indicate that the bulb is indeed on. However, if the bulb is not on, we do not need another symbol to say so, but we should define the condition when **A** is not true (false). We can do this

by putting a bar over the A and saying $\bar{A}$ (read as "A not") means the bulb is not on. We have defined the two possible states of the bulb as A for on; $\bar{A}$ for off.

We can apply this logic to any fact and make a statement that is true (A) or false ($\bar{A}$). It is easy to decide which state exists in binary notation if we use the figure one (1) as the true state and we use zero (Ø) as the false state. This binary notation allows A to assume either the 1 or Ø state, and $\bar{A}$ will be the negation, or inverse. If we were to say, "The light (A) is on," and the light is really on, the statement is true and A equals 1. However, if the light is really off, then the statement is false and A equals Ø.

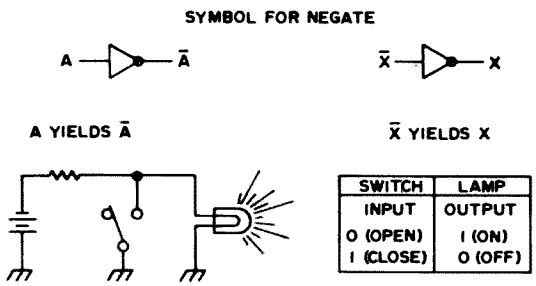

Fig. 3. A simple inverter can be used to negate a logic function.

We may also make a statement of negation. By saying, "The light is not on," the statement will be true when the light is off, and $\bar{A}$ will be equal to 1. These terms, once defined, are often used interchangeably in describing logical operations.

By combining logical conditions in gates, we can produce an output at any time, or in any sequence that we may desire. We can amplify, invert, combine, store, or compare logic levels by using gates and flip-flops. Logic symbols and operations will be described before we get into the operation of the button box, so if at present you are thoroughly confused, don't despair, for now that we know what a logical statement is, let's see how we can shorten it to symbols that when interconnected can tell us how something works.

The AND Gate

An *and* gate must have all of its inputs true in order for the output to be true. If we combine soil "A" and water "B", the result is mud "C". This statement may be

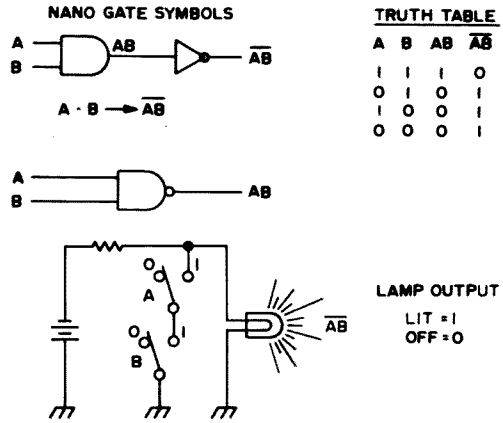

Fig. 4. The nand gate is an and gate whose output is negated. The switch arrangement shows a mechanical circuit equivalent of a typical nand function.

written as A•B→C, or simply AB→C, and is read A and B yields C. Switches can be used to more clearly show the operation of an *and* gate (see Fig. 1). Conditions of the inputs and outputs in the truth tables show the relationships.

Examination of Fig. 1 will show that only when switches A and B are both closed will the light C be turned on. We can say then that in *and* gates, the key word to remember is *all* and that all inputs must be at the true (1) level to produce a true (1) output. Also, the *control* for the *and* gate is Ø, since any Ø at the input will cause the output to be false (Ø).

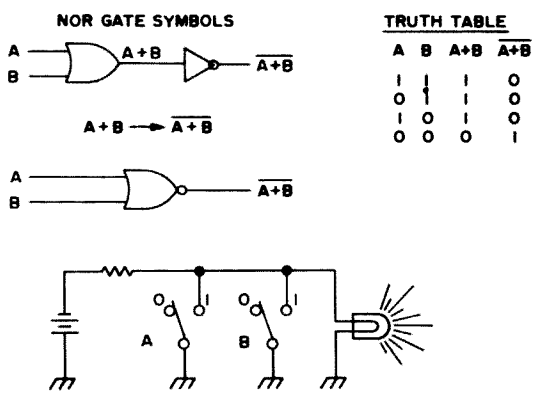

Fig. 5. The nor function, as shown by the switch assembly, produces a negated result (light goes out) when any input is at 1.

The OR Gate

The *or* gate performs a logical function by allowing a true output whenever one or more of the inputs are true. The *or* function is designated by the + sign. The

statement A + B → C is read A *or* B yields C. Operation of the *or* gate can also be seen by examination of the relationship of the inputs to the output in the truth table of Fig. 2.

It can be seen in Fig. 2 that when either, or both, of the switches close, the light will be on. We can say of the *or* gate that *any* is the *key word*, and that if *any* of the inputs are at the true (1) level, the output will be at the 1 level. We may also say that the *control* is a 1, since any 1 at the input will cause the output to be a 1.

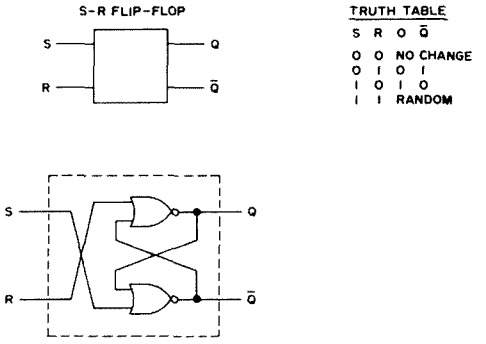

Fig. 6. Cross connected inverting gates form flip-flops that operate similarly to the manner of a latch relay.

Invert/Negate

To negate a function, an inverter is required. If A is the input to an inverter, the output will be $\bar{A}$. The symbol and function are shown by Fig. 3. Quite a few of the logic boards available on today's surplus market do not use the direct *and/or* functions, but have an inverter following the gate. If the function is not understood, these can cause problems in implementing the logic to create the desired output.

The NAND Gate

The *nand* function is the *and* function negated, or the contraction of "*not and*".

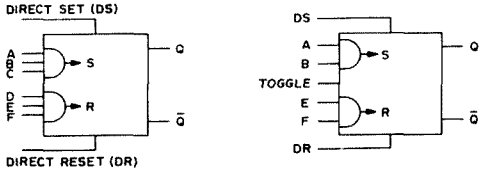

Fig. 7. Multipurpose flip-flops may have a number of triggering inputs, selected to match the requirements of specific circuits.

BRAND NEW FREQ-SHIFT TTY MONITOR:
NAVY OCT-3: FM Receiver type, freq. range 1 to 26 MHz in 4 bands, cont. tuning. Crystal calib. Reads up to 1500 Hz deviation on built-in VTVM. Cost $1100.00 each! In original box, with instruct. book & cord, fob Mariposa, Cal. Shpg wt 110 lbs. **49.50**

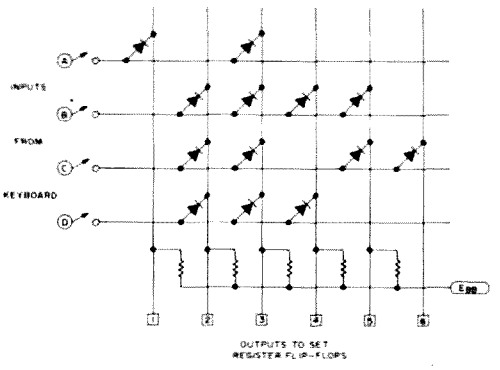

Fig. 8. The encoder, or matrix, causes simultaneous outputs with but a single input signal.

To understand the operation of the *nand* gate, note that the *and* function at the input must be satisfied to cause the $\emptyset$ output, represented by extinguishing the lamp of Fig. 4. The *nand* gate yields a 1 output until *all* inputs are at the 1 level. The *key word* in a *nand* gate then, is all, because all inputs must be at the 1 level to produce a $\emptyset$ (negation of *and*) at the output. Since any $\emptyset$ input will cause the output to be a 1, the control is a $\emptyset$.

The NOR Gate

The *nor* function is the *or* function negated, or the contraction of "*not or*." In Fig. 5, note that when the *or* function is satisfied, the *nor* output of $\emptyset$ is indicated by extinguishing the lamp. The *nor* gate yields a $\emptyset$ output until none of the inputs are at the 1 level. The *key word* in a *nor* gate then, is *none*, and since any 1 will yield a $\emptyset$ output, the *control* is a 1.

Flip-Flops

Nor gates and *nand* gates are often cross connected to form a stable set-reset (S/R) flip-flop. An input pulse to either the S or R inputs will cause a condition in the output that will not change with additional input pulses applied to that same input line (Fig. 6).

By utilizing *and/or* gates to route the input signals, the simple S-R flip-flop may become a multipurpose flip-flop and can be used not only for storage, but as binary dividers, counters, shift registers, and other uses, such as oscillators, phase shifters, etc. The symbol for a multipurpose flip-flop

differs from the S-R only by the number of inputs shown (see Fig. 7). Flip-flops can be series connected and used for serial shift registers, such as the one used in the button box.

Encoder

An encoder is variously called a matrix, an expander, a coding gate, and other names – but regardless of terminology, the function is to cause simultaneous events on a multiple output with a single input signal (Fig. 8). A single input, such as closing the switch for the letter C, will cause outputs on corresponding lines – in this case, lines 2, 3, 5, and 6.

The layout for the diode matrix board used as an encoder in the button box is shown in Fig. 9. Each of the encoder inputs comes from a separate keyboard switch. Closure of any switch will cause an output on one or more of the ten lines feeding the input gates to the shift register (*and* gates in Fig. 10; *nand* gates in Fig. 12). Setting a stage of the shift register tells the code generator (CG) when to turn off.

The matrix board can be etched at the kitchen sink (send the wife to the movies while you do this), and holes drilled to pass the diode lead through the board for gate wiring, or you can use predrilled Vector board. A sheet of either is adequate as long

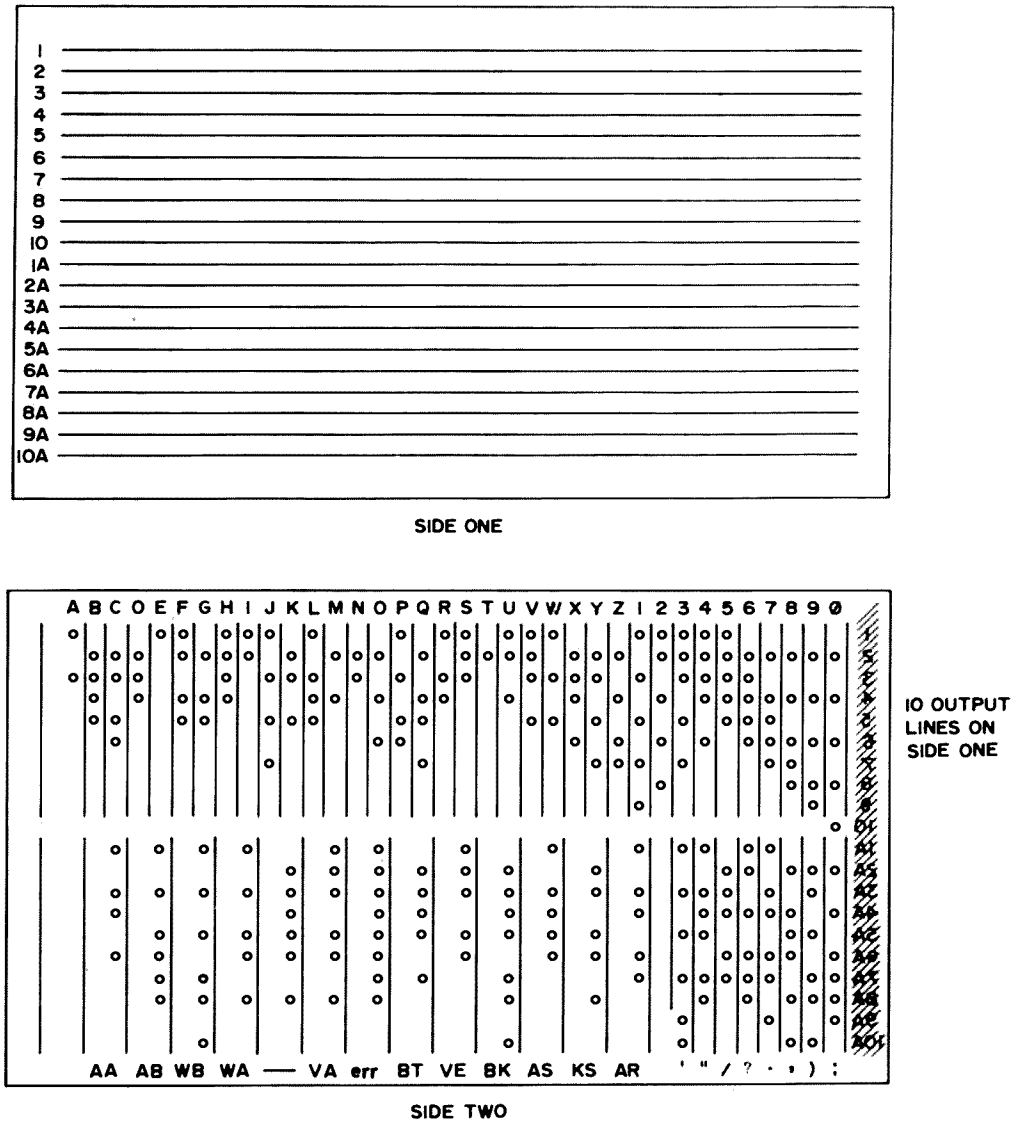

Fig. 9. Diode matrix for button box.

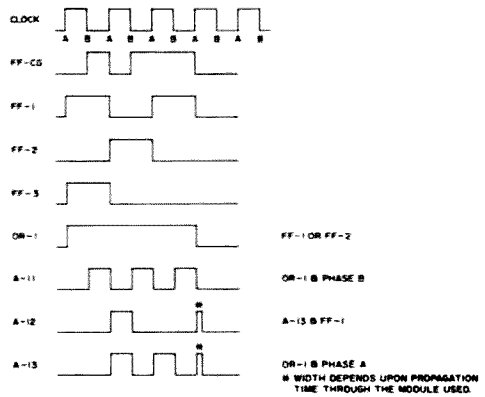

Fig. 11. Timing signals for button-box logic elements.

as there are at least 20 holes across the width and 32 along the length. Hole spacing is determined by the physical size of the diodes you use. Use a heatsink when you solder them to the etched board or the wires on the Vector board, for it is disconcerting to have a bad diode on the first check.

How It Works

Now that we are speaking the same language, and understand the basic building blocks used in this keyboard, or for that matter in any other digital device, let's see what sequence of events must occur in generating CW characters. Examine the simplified logic diagram shown in Fig. 10, and follow the sequence of events on the timing diagram, Fig. 11, for the generation of the letter A in Morse code.When the button of the keyboard is pressed corresponding to the letter A, the encoder output will cause a 1 level to be seen at the "b" inputs to *and* gates A-1 and A-3. For these inputs to appear at the output of the *and* gates, two other conditions (a and c) must be met. Input "a" will be at the 1 level only when all of the flip-flops which comprise the shift-register have been reset to the Ø state. This causes a Ø output from OR-1, which is inverted in 1-2, and places a 1 level on the "a" input to *and* gates A-1 through A-10. With the "b" and "a" inputs enabled on gates A-1 and A-3, but only the "a" input enabled to all others, the appearance of a clock phase "A" to all the "c" inputs will allow gates A-1 and A-3 to set

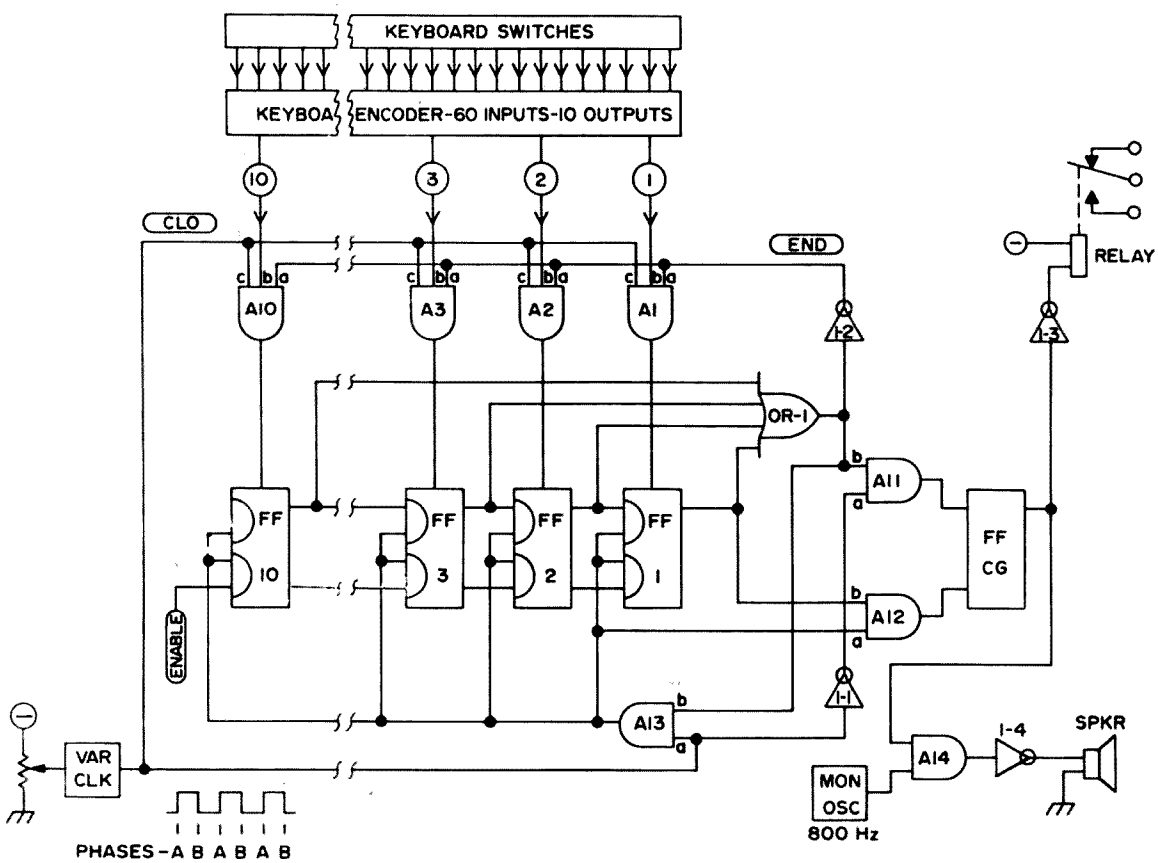

Fig. 10. Logic scheme of keyboard encoder.

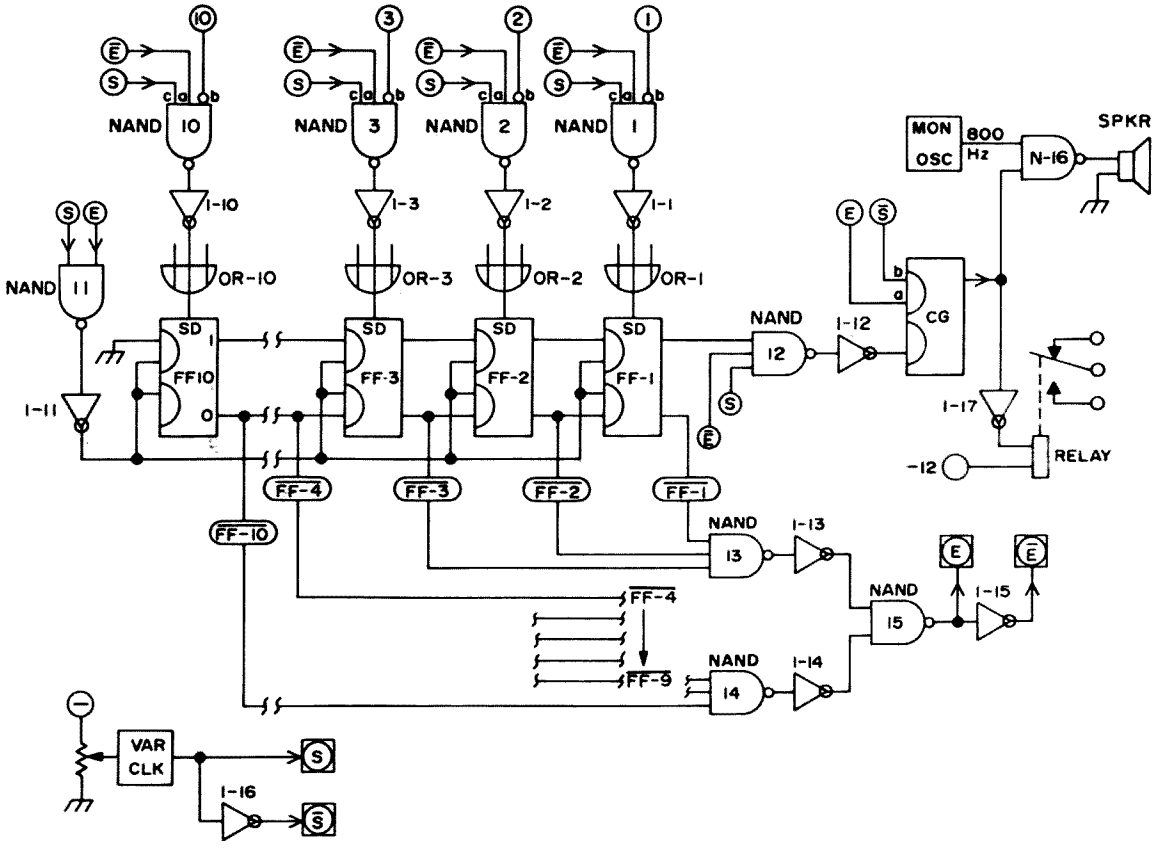

Fig. 12. Nand *logic equivalents for button-box inputs and shift register.*

flip-flops FF-1 and FF-3 to the "1" state. As soon as FF-1 and FF-3 are set, the "1" output of OR-1 causes 1-2 to place a "Ø" level on "a" inputs to the *and* gates A-1 through A-10, thus inhibiting further input from the keyboard until we have completed transmitting the letter "A" that we just placed into storage.

We now have a 1 stored in FF-1 and FF-3, input "b" of A-11 and input "b" of A-13 enabled by the 1 output of OR-1. The first clock phase "A" leading edge allowed the register to be set, but did not get through A-13, since the "b" input was not enabled at the time clock phase "A" arrived, so no shift occurs. Clock phase "B" leading edge now arrives at 1-1, is inverted and is applied to "a" of A-11 which is already enabled by the "b" input. The output of A-11 triggers FF-CG to the set state, keying the output 1-3 and the monitor A-14, allowing the monitor oscillator to be amplified by 1-4. The inverter amplifier 1-3 is shown as a relay driver, but could as easily be the transistor keying unit of a transmitter.

Meanwhile, back in the keyer logic, we now have FF-CG set, a 1 stored in FF-1 and FF-3, OR-1 is still enabling A-11 and A-13 on the "b" inputs, A-1 through A-10 are inhibited by the action of 1-2, and all is in the proper condition for the arrival of the next clock phase "A".

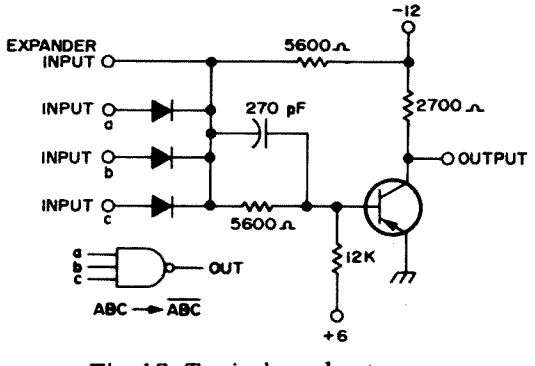

Fig. 13. Typical nand *gate.*

When clock phase "A" goes to the "1" state, here is what happens: A-11 is inhibited by 1-1 and goes to Ø thus closing the set side of FF-CG. The leading edge of clock phase "A" also affects A-13, input "a", and is passed through to the trigger inputs

CRYSTAL BARGAINS

Depend on . . .

We can supply crystals from 16 KHz to 80 MHz in many types of holders. Fig. 14. Typical or *gate. These gates are made into single set-direct drivers by separating the outputs.*

of FF-1 through FF-10, and to the "a" input of A-12 on the reset side of FF-CG. Input "b" of A-12 is enabled by the "1" standing on the output of FF-1, and the output of A-12 causes FF-CG to reset, or go to a "Ø" state at the output, completing the first dot, and releasing both the monitor and keying unit.

At the same time that FF-CG is reset, all information stored in FF-1 through FF-10 is shifted toward FF-CG one position. FF-1 is now in the "Ø" state, FF-2 assumes the "1" state from FF-3, and FF-3 through FF-10 are now in the "Ø" state. Notice that the reset gate of FF-10 is enabled. This is

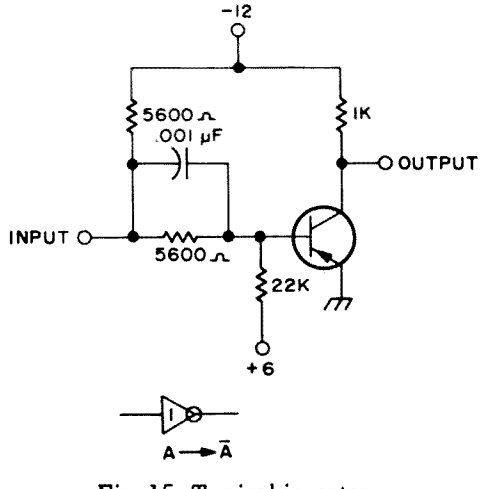

Fig. 15. Typical inverter.

to assure that the shift register will fill up with "Ø" as the shift sequence occurs, and will tell us when a character is complete.

Output levels will now be in the following states: A-1 through A-10 at Ø; A-11 at Ø; A-12 and A-13 at 1; FF-1 at Ø; FF-2 at 1; FF-3 through FF-10 at Ø; FF-CG at Ø; A-14 at Ø; and 1-3 open (unkeyed). These conditions remain until the arrival of clock phase "B".

Clock phase "B" follows the same sequence as before; that is, it inhibits A-13, enables A-11 and sets FF-CG to a 1. Generation of the dash has now started, and nothing else occurs until arrival of the next clock phase "A". Let's see how the dash is made the proper length.

When clock phase "A" arrives, 1-1 inhibits A-11. At the same time, A-13 is enabled and triggers FF-1 through FF-10, and tries to reset FF-CG through gate A-12. But now FF-1 is in the Ø state and is inhibiting the "b" input of A-12, so that

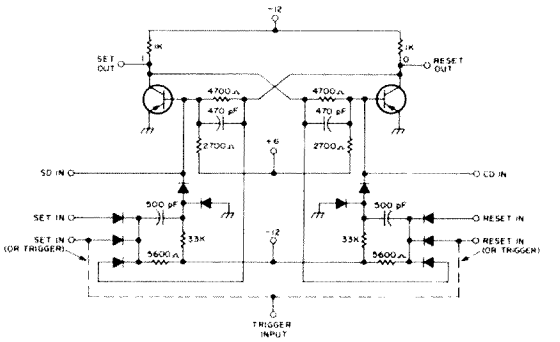

Fig. 16. Typical flip-flop.

the clock phase "A" does not reset the FF-CG. The output remains keyed and we have generated the first one-third of the dash, and at the arrival of the next clock phase "B" will have generated the second one-third of the dash. All that clock phase "B" can do upon arrival is enable A-11 and inhibit A-13. Nothing else will be affected because FF-CG is already in the 1 state, and removal of the 1 level from the trigger inputs to FF-1 through FF-10 causes no action. The output is still keyed, and two-thirds of a dash has been generated, and nothing will change until the arrival of the next clock phase "A".

When clock phase "A" arrives, 1-1 will inhibit A-11, A-13 will be enabled, placing a 1 on the "a" input to A-12. A-13 will trigger FF-1 through FF-10, and the 1 that

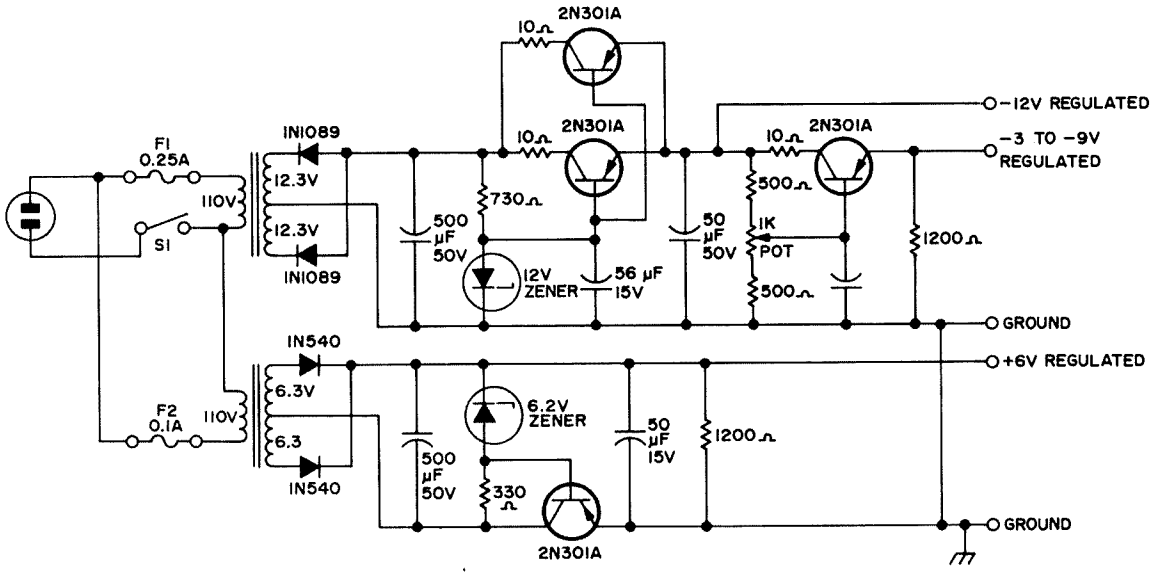

Fig. 17. Regulated power supply.

was stored in FF-1 will be seen at the "b" input of A-12, causing a 1 on the output to reset FF-CG. When FF-CG resets, the monitor gate A-14 is inhibited and 1-3, the drive for the relay is removed, thus opening the keyed output. One dash, three times the length of one dot, has now been generated, but we are not yet complete, even though we have ended the transmission of the dash. What happens now?

If you will think back to the start of this sequence, we allowed the shift register to accept an input at clock phase "A", but did not actually begin transmitting until we set FF-CG at clock phase "B". This delay is part of the space required between characters. The length of a space is the same as a dash, and we have already generated one-third of the space at the beginning of each character, so let's complete the sequence and see how we generate the other two-thirds of the required spacing.

Now, look closely at the logic diagram and examine the conditions awaiting the arrival of clock phase "B". Gate A-11 is inhibited because OR-1 is now at the $\emptyset$ level, since all the 1 levels stored in the register have been used and shifted out. OR-1 does not allow clock phase "B" to set FF-CG. The only tricky part of this arrangement is the loop propagation time through A-13, FF-1, OR-1, and with the clock speeds used here (4–100 pps) any propagation delay up to approximately 100 μsec is all right.

Since the arrival of clock phase "B" had no effect on the output (still unkeyed), the next clock phase "A" may or may not start the generation of another character, depending upon the input encoder. If any button on the keyboard is pressed (including still holding down the letter "A" button) generation of another character will start at clock phase "A". If a button is not pressed, no output will occur until we once more have a coincidence between the encoder output (button pushed) and clock phase "A".

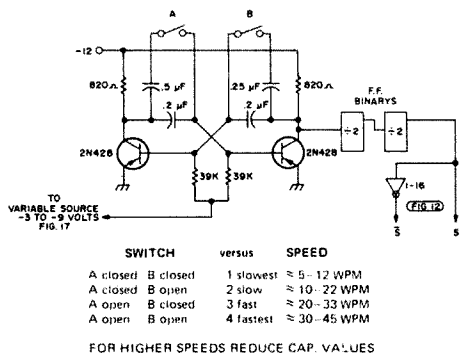

Fig. 18. Variable clock.

In summary, the following is the sequence of events in generating a character: A button is pushed, encoding a character; phase "A" transfers the character into the shift register (memory) and generates one-third of a letter space; phase "B" sets the code generator; phase "A" resets the code generator, dependent upon the state of FF-1, and shifts the stored word one place

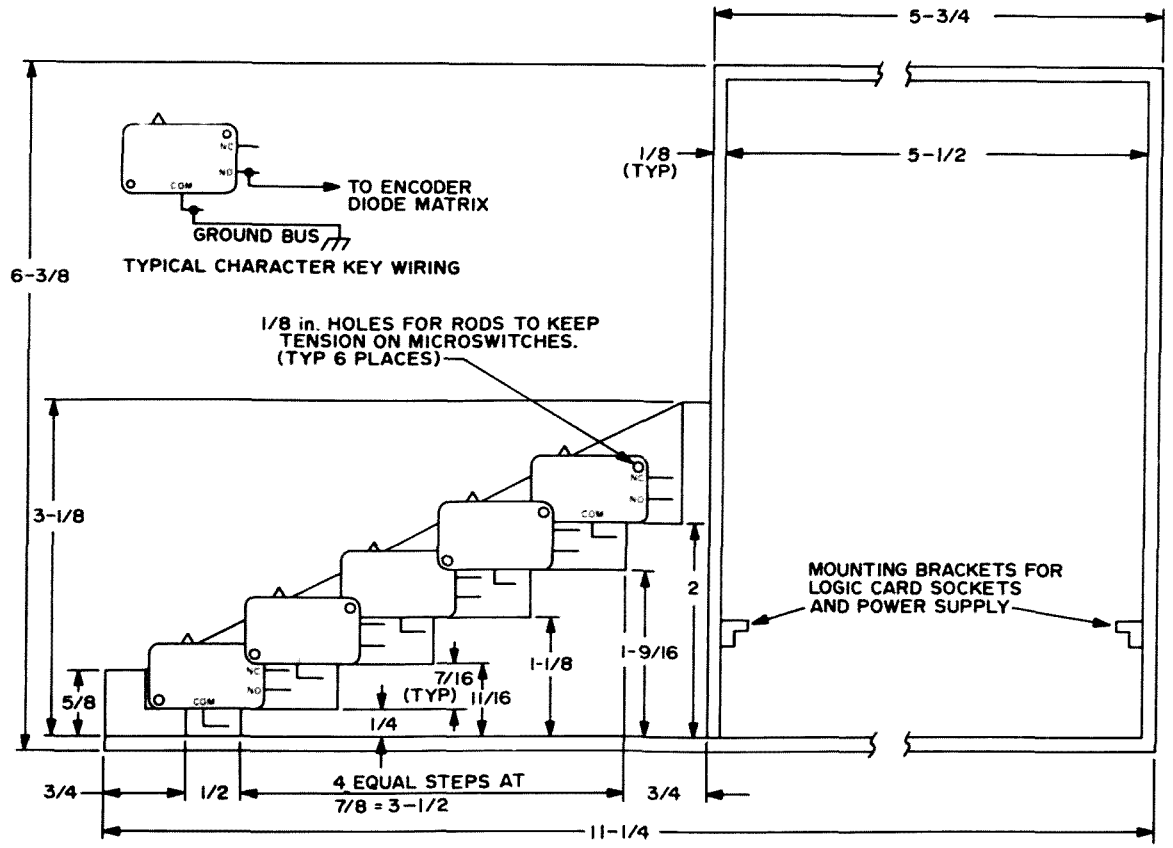

Fig. 20. Side view of button box, with dimensions.

(bit); upon emptying the register, OR-1 and phase "B" generate two-thirds of a letter space.

While the description does get rather involved, it is far simpler to make the button box work than to describe what goes on inside.

Gate Reduction

With possibly some decrease in reliability, gate OR-1 could be reduced to a two-input gate. I don't recommend doing it, but in case someone wants to reduce the number of gate inputs, here is the reasoning for doing so.

Since either FF-1 or FF-2 are set during the generation of any character, it is only necessary to examine the state of these two flip-flops to determine either that the shift register is clear or that a character is being transmitted. As long as either FF-1 or FF-2 is set to a 1 state, the keyboard input gates are inhibited, and the shift gates are enabled. When both FF-1 and FF-2 are in the $\emptyset$ state, further clock pulses are inhibited from setting the code generator or shifting the register, but the keyboard transfer gates are enabled for input of another character from the keyboard.

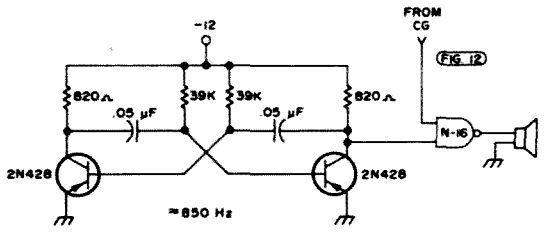

Fig. 19. Monitor oscillator.

Further Notes

Logic cards available at surplus outlets, as well as most of the integrated circuits being sold at bargain prices seem to contain *nand* gates as the standard. Figure 12 shows the implementation of the button box using *nand* logic.

Schematics of typical circuits (i.e., the ones I used) are shown in Figs. 13–19. Let me repeat – there is nothing sacred about these, so if you have some different circuits, and the logic levels are compatible,

don't hesitate to substitute. If you use ICs, stay with DTL or RTL, whichever you start with, right on through, for they don't work too well when you mix them up.

The oscillator and divider I used for speed control is a bit unusual, but I had the cards and it was simply a matter of expediency that I used them rather than devise another type – such as unijunction – to use for a clock. The same goes for the monitor oscillator (Fig. 19).

If you decide to use "micro" switches – as opposed to building or buying the keyboard – the dimensions shown in Figs. 20 and 21 should be helpful. I used eighth-inch drill rod threaded for 6-32 nuts on both ends to fasten the rows of switches together, with spacers required only on the top and bottom rods for switch separation.

The dowels can be turned on a lathe if one is available, but the turning is not necessary if large enough holes are drilled in the top plate.

By using plywood, the only tools required are generally available to anyone. A handsaw, a rasp, a screwdriver, a drill, a few tears shed after finding a board still too short after already sawing it off twice, and some glue are all you need to fasten the button box together. Your own ingenuity will tell you how to make plug-in sockets for your cards.

Be sure you leave some extra space for additional cards and switches, because you will probably want to make another encoder board for Teletype transmission, controls for the station, a timer, or some other goody. One thing I do not recommend adding – and that is an additional memory. I find that staying right with – or

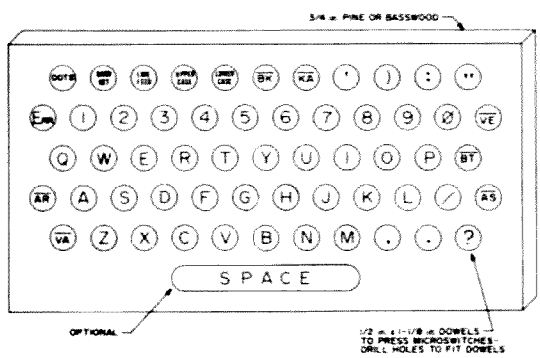

Fig. 21. Keyboard layout.

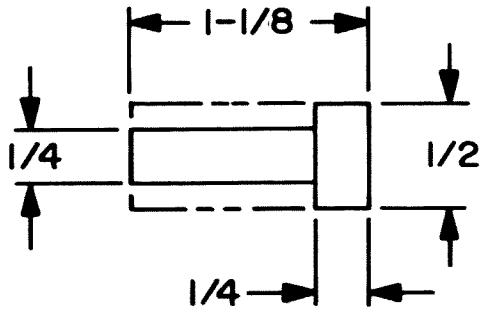

Fig. 21a. Detailed view of button.

half a letter ahead of the letter being transmitted is not difficult, but trying to type something, and listen two or so letters behind the letter you are typing is directly opposite the method used to copy code. To say the least, it is very disconcerting. But additional memory can be added without much problem.

Build one of these button boxes, practice a few minutes to get the hang of it, and hit the airways prepared to enjoy a brand of CW that is more enjoyable than any you have encountered before. Oh yes, you should buy a bigger hat before you start using it on the air, because you are sure to get a swelled head for all the compliments on your fine fist.

MARCH MCMLXXII Monthly Ham

HAM DOC HEALS VETS

Reprinted from The Rockland County Journal-News, Nyack, N.Y., Dec. 21, 1971.

By Gale Tollin
Associated Press Writer
Minneapolis, Minn.

(AP) —His friends call him "Doc" but Felton Jenkins is a physicist-engineer and not a physician. He does his healing in the basement of his home, using eight powerful shortwave radios and three telephone lines to deliver therapy to wounded servicemen in Vietnam.

'It's my way of saying thanks to the boys," explains Jenkins.

For the past four years Jenkins has been devoting much of his time and money to putting wounded soliders in voice contact with their families. Six days a week – with Sundays off – he is up at 6 a.m. seated among his microphones, dials and speakers. He handles 25 to 30 contacts each morning, in about three hours, and the number has run as high as 37 when conditions are favorable.

The soldier's conversations with home, Jenkins feels, have medical benefits – especially when nervousness and loneliness figure in the wounded man's condition.

Frequently Jenkins works through the Military Affiliate Radio System – MARS. Ham radio operators in Vietnam patch into a telephone which is taken to the bed of a soldier in a military hospital or on the hospital ships Sanctuary and Repose, anchored off the Vietnam coast.

Jenkins is on the U.S. end of the transmission. He calls the soldier's family by telephone and patches the conversation into his radio.

If the father is at work and the mother at home, Jenkins phones each of them on different lines and patches them into a conference call. The result is that the son in Vietnam, father on his job and mother in her home can chat in a three-way conversation.

"It's like a party line." said Jenkins. "It gives me a certain amount of pleasure to be able to do something for somebody else." he said. "I look at life as a great big mirror. You look in it and smile and it smiles back."

His hobby, he said, brings him satisfactions that can't be measured in dollars.

As an example, he recalled the case of an American solider who had lost both legs in Vietnam.

"His spirits were low, and he wasn't cooperating with the doctors." Jenkins said. "The doctors were about ready to give up on this boy, and they asked me if I couldn't arrange for him to talk with his parents.

"The parents happened to live in Mexico and it wasn't the easiest thing in the world to get them to a telephone. I had a friend in Mexico pick them up and bring them to his radio. We patched them through to their son.."

A business executive friend of Jenkins heard the conversation in Texas on his own ham radio. He broke into the conversation and asked to talk to the boy. He told him he would give him a job. Jenkins and the Texan asked another friend, who heads a string of business schools to forego tuition for the soldier and the third man agreed. The amputee was flown from Vietnam, entered the school, was graduated and went to work in a business owned by the Texan.

"He turned out to be one of the finest employees this firm has ever had." Jenkins added.

Doc Jenkins leaned back in his swivel chair, amid his radio equipment, and summed up his feelings: "You see, some of our work does have its dividends."

Boy Scouts in Radio AWARD OFFERED

Explorer Post 160 of Fairmont MN is sponsoring the Friends of Scouting award. The purpose of this award is to promote the exchange of ideas, memories, planning of future Scouting events, develop interest in the Scouts, and so on. To obtain the certificate, you must work any 25 current members in the Scouts in any country where they may be registered. Exchange QSL and GCR list (i.e., Scouting position such as Cub, Boy Scout, Explorer, Committeeman, Scoutmaster, etc.). Send these with a dollar to Explorer Post 160, c/o Twin Valley Council, Box 22, Mankato MN 56001. SWLs are also eligible for the award.

Other Scouting awards that are available from the Boys' Life Radio Club (Certificate Department, B.S.A., North Brunswick NJ 08903) are the Worked Every Region–B.S.A. This is for submission of QSLs verifying contacts with members of the Scouts in the twelve Scouting Regions. The WAS-BSA is for working Scouters in the fifty states. Only SWLs may earn the Call Area Specialist certificate for verifying stations in all 10 U.S. call areas; and the World Listener award is issued for submitting cards from 25 different countries, at least one from each of the six continents.

NEW MOBILE XCVR

Linear Systems announced recently that it would be entering the two meter FM field with its new SBE model SB-144. The new transceiver is ideally suited for the mobile installation. It has twelve channel capability, ten watts power output, back-lit channel selector dial, and combination S-RF meter. Comes complete with mike, three sets of popular crystals, and mobile mounting bracket. Write to *Linear Systems, 220 Airport Blvd., Watsonville CA 95076.*

L to R: Mr. S. E. Fellerman K3FEC, of Kensington, Maryland; Dr. Robert R. Rodman WB4JAW, of Springfield, Virginia; Mrs. Terri Simons; XYL of the late Bert Simons; K4YLP; and Mr. Wilmer G. Rogers WA4OPW, of Ashland, Virginia.

FIRST K4YLP MEMORIAL AWARD PRESENTED

At a recent meeting of the Virginia Amateur Radio Association in Richmond, Virginia, the first K4YLP Memorial Award was presented to Wilmer G. Rogers WA4OPW by Mrs. Terri Simons, XYL of the late Bert Simons K4YLP. Wilmer, an avid DXer, was selected on the basis of the kindness, consideration and courtesy shown in the field of amateur radio.

W.G., as some of his friends call him, is a past president of V.A.R.A. He has given his time unselfishly training prospective hams, helping fellow hams with antenna problems, organizing club activities such as field days and picnics, running phone patches and many other things contributing to the hobby and the Association.

This award was made possible by the Lox & Bagels Radio Club, an organization of amateur radio operators spanning the east coast. The award, an impressive certificate and a $25 savings bond, will be awarded yearly to the member of the Virginia Amateur Radio Association who most displays the qualifications exemplary of those traits displayed by the late Bert Simons.

IN PUEBLO COLORADO

REPORT ON HUNTOON TALK

John Huntoon, ARRL General Manager, recently spoke before the Pueblo (CO) Ham Club. He commented on League activities and policies, and made some interesting comments about the 200 MHz band. After saying that the CBers stand a 50-50 chance of getting part of the band, he went on to say that the League has not filed against the proposal and that the FCC has not definitely recommended it; "If it comes to be, it will hurt, but won't hurt much since the advent of two meter FM . . . If you object, please write your League and it [220] most likely could be the next repeater band."

Following is a reprint of one man's opinion of Huntoon's presentation, *courtesy of The Grid Leak*:

After Huntoon's lecture he opened the floor for questions and discussion and our local hams in my opinion really put Huntoon through the good old fashioned ringer. Some of the questions asked were as follows: Why QST didn't carry more articles pertaining to the subject of FM and FM repeaters? Why didn't ARRL print manuals concerning the FM mode of transmission and repeaters? Why is QST so difficult to read and understand? Why is the FCC calling in at this time Technician and General conditionals for re-examination? What are the chances of the CBers getting the 220 band?

Mr Huntoon stated that in the future there will be more articles concerning FM and FM repeaters. There is an ARRL manual on FM in the process of being prepared and should be ready either in the latter part of 1972 or the early part of 1973. QST will be more readable in the future. Last year he felt the chances of the CBers getting the 220 band were 10 to 1 against their getting it, but as of today he felt that they stood a better than 50-50 chance of getting this band.

His answer to the questions about the Techs and Conditionals kind of gave me a sour taste in my mouth and left me with the feeling that the ARRL as an organization is rather inept and really isn't in too much of a hurry to see the amateur ranks grow. He stated that in his opnion many conditional licenses were obtained fraudulently and if a ham is really interested in ham radio recall by the FCC should hold no fear for the operator. At this point if it hadn't been for Chuck Chambers KØYFR holding me, I might have fallen either to or through the floor.

Most of the hams at the meeting disagreed with the above mentioned answer for a number of reasons. I for one disagree with his answer and the FCC actions for the following reasons: The average Tech conditional because of the bands allotted to him has very little opportunity to use CW. The average General conditional usually uses phone as is the practice amongst most hams. And besides when an individual gets into ham radio and starts operating he usually forgets all the fine points of theory he learned when he was studying for his examination.

Most licensed professions that I am acquainted with never require their licensees to ever have to take another exam to prove their proficiency, even if the individual has been licensed under a "grandfather clause." Now I realize that ham radio is not a profession, but it is a licensed hobby and consequently I feel that the law as it applies to licensing anything should apply. And the law on that point is that it is illegal and a clear example of double jeopardy when an individual has to be subjected either to trial for the same offense or to examination in a profession or hobby for which he already has been issued a license.

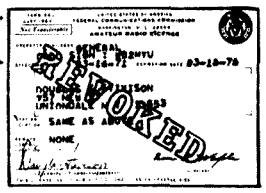
In private conversation with Mr. Huntoon, I told him I felt that the ARRL doesn't seem to go too far out of its way battling for hams when various legal situations arise. He told me that to a great extent I was correct because the ARRL lacks funds to get involved in legal and other situations that may arise all over the country.

Unions defend their union members.

Professional associations defend their members.

Why shouldn't ARRL defend its ham members?

Dr. Morris Levinson WBØBSV



At Long Beach

YL'S TO MEET

Women amateur radio operators will gather at Long Beach, California during the long holiday weekend of May 26–28, 1972. The Sixth International YLRL Convention marks the 33rd year of this organization's activities. As 33 has become the traditional sign-off for QSO's between YL's, the 33rd birthday celebration is a high point in the history of this organization of women amateurs from all over the world, now numbering close to a thousand members. The convention will have headquarters, operating station, meetings, entertainment, birthday luncheon and "cruise" banquet at the Edgewater Hyatt House on Pacific Coast Highway overlooking the Long Beach Marina.

The YL's will entertain their OM's with a tour of the Swan Electronics plant in Oceanside on Saturday, May 27th, returning to the Edgewater for a luau. A visit to the Queen Mary and other harbor points of interest is planned. But the event these YL's anticipate with the greatest interest is meeting in "eyelash QSO's" the YL's they have met on the air or will look for on the air once they return to their home QTH and with whom they share their exciting hobby in friendship, public service and ever-expanding horizons. Los Angeles YL's hosting this convention encourage all who attend to come supplied with a pocket full of snapshots for "swaps" to exchange with calls and autographs. They look forward to seeing Darleen Souligny WA6FSC, who spent much of 1971 traveling and meeting DXers around the world. This year's YLRL President who will preside at the convention is Mae Hipp K7QGO of Sparks, Nevada.

WITH THE FCC

There have been some questions about FM deviation used on six and ten meters. The following reply to a letter of inquiry by W6YAN clarifies the issue:

Section 97.65(c) of the Commission's rules require that F3 emissions used between 50.1–52.5 MHz occupy the same bandwidth as a A3 signal or 6 kHz. Part 2 of the Commission's rules (§2.202) defines bandwidth of an F3 signal as equal to two times the maximum modulation frequency plus two times the quantity one half the difference between the maximum and minimum values of the instantaneous frequency. (B_n = 2M + 2D). As you can caluculate, if the audio modulation is 3 kHz, D must be zero.

FCC-Amateur Rules Section

* * *

A. Prose Walker, chief of the Amateur and CB Division of the FCC, has indicated FCC thoughts about these services. In an interview with *CB Magazine* (January, 1972) Mr. Walker answered several questions that are foremost on the minds of many hams. As far as a license without a code test, there is a possibility that such a provision will be made. When asked about this, he stated, "The International Radio Regulations of the ITU to which the United States is a signatory, contains various provisions relating to the operation of radio stations. Article 41, paragraph 3 (1) states that Administrations may waive the requirement for capability in Morse code in the case of amateur stations making use exclusively of frequencies above 144 MHz. For years we have been told that one of the reasons why more licensees in Citizens Radio do not progress to Amateur Radio is because of the requirement for the code. Even though the code requirement for the Novice and Technician license is only 5 words per minute, indications are that it is still a hindrance. We believe that 5 words per

Amateur Radio, August 1971. New Zealand has been working on a 2 meter band plan for the country. In the draft plan we received, they have made provision for all modes of operation. There are FM simplex channels every 50 kHz from 145.8 to 146.2 MHz, with 145.85, 146.0 and 146.15 MHz, as the prime channels. 146.0 MHz to be first. On the FM repeater side they have allocated four channels on 700 kHz spacing. A pity, as it does not make them compatible to Australia. Inputs on 146.3, .35, .4 and .45 with the outputs on 145.6, .65, .7 and .75. The three-channel AM repeater systems have inputs on 144.6, .65 and .7 with the outputs on 145.725, .775 and .825. 144.8 MHz, is set aside as an RTTY net frequency. The beacons are on the "hundred" equal to the call area, e.g. ZL1 on 145.1, ZL2 on 145.2, ZL3 on 145.3, and ZL4 on 145.4 MHz. The segment 144.0 to 144.1 MHz is set aside as DX and experimental working. 144.1 to 144.5 MHz is a general working segment.

Federal Repeater Secretariat.

minute is a bare minimum, and is not difficult to achieve with proper application of effort. Nevertheless, we are actively considering amending portions of Part 97 of the Rules and Regulations for the Amateur Service which would permit operation above 144 MHz without the code requirement included in the examination. In all likelihood, there will be two classes of no-code license. One will be roughly equivalent to the General Class but for VHF and UHF operation; and the other equivalent to the Advanced or Extra Class covering only above 144 MHz. The examination will be completely new and will cover VHF and UHF related technical matters. Another aspect we are also considering is to possibly require the licensee of an Amateur Repeater station to hold the higher class of license."

The EIA proposal that would eliminate several megahertz of the amateur 220 MHz band and change them into a Class D Citizens Band was another topic for discussion. Mr. Walker had this to say about RM-1747: "We have given it considerable attention over the past months since it was filed with the Commission. The decision has not yet been taken whether to issue a Notice of Proposed Rule Making. There are various factors involved such as the priority of use of the 220 MHz area of the spectrum; the possibilities of other needed uses if a change in the existing allocation were to be considered; what would happen to 27 MHz if the band for CB were changed; whether the same type of operation as now exists on 27 MHz would also prevail on 220 MHz and what would be the ramifications of that; whether the CB user actually wants or needs such a drastic change in the spectrum allocation for the Service or whether the proposed plan is primarily for the benefit of the manufacturer in opening up a new market. Details of all these and other considerations would take up a great deal of time. Let me assure you again that we are giving most serious consideration to RM-1747, but we are not on the verge of a decision as to exactly what is the best course to follow. You know that we are charged with the administration of the CB Service and therefore we must give full consideration to the maximum benefits to be derived by the licensees from whatever course is followed. Obviously, no one would desire opening up a new area of the spectrum without the assurance that the operation to be expected would be an improvement over that now obtained on 27 MHz. You also know that the band 220–225 MHz is currently allocated to the Amateur Service on a second priority basis to Government. No doubt the Amateurs would like to be heard whenever the moment is propitious, such as the possible issuance of a Notice of Proposed Rule Making. I repeat, we have not yet reached a conclusion as to the manner in which we shall dispose of RM-1747."

As for the current abuses of the Citizens Band on 27 MHz, Mr. Walker mentioned that working skip is not the main problem; "Actually, there are many others of a more serious nature which have nothing whatsoever to do with long distance transmission; failure to identify, use of pseudonyms in lieu of call signs, foul and obscene language, threats of bodily harm to others, use of high-power linear amplifiers, operation on frequencies not allocated to the Service, intentional interference, and many others which reduce the potential usefulness of the Service for those who wish to use it for the purposes intended." He mentioned that these violations are being taken into consideration. He further indicated that a very large amount of self-regulation must prevail if the Citizens Service is to perform its intended function. "One of the most useful procedures would be to emulate the degree of self-regulation that has prevailed in the Amateur Service for the past 50 years."

HAM INJURED IN ATTACK BY 'QST'

by WA1NQJ (Special from The Squelch Tale)

K1RGQ was viciously attacked by QST Magazine recently. However, showing true heroism and amateur spirit, he rescued his Swan and Regency, sustaining an injury to his arm in the fray. John assured us that he is now fully recuperated.

While tuning in on K1FFK – 6 meters – and eagerly peaking his wattmeter, John saw that his homemade bookshelf containing many, many years of back issues of QST Magazine was beginning to topple. If things had fallen in the direction they were headed, all of his gear would have been knocked off his operating table to oblivion. John, anticipating damage to his gear, threw himself over it; the magazines and bookshelf fell, throwing John to the floor and pinning him there. Alone in the house, it took John approximately an hour to extricate himself. He is happy to report that his arm is fine now and that none of his gear was damaged.

SEMICONDUCTOR NEWS

D. Thorpe

RCA says goodbye to germanium and silicon small-signal transistors.

RCA's Solid State Division has decided to phase out over one hundred types of small-signal transistors. Included in the cutback is the whole line of small-signal silicon transistors. The devices discontinued are as follows:
Silicon: 2N2475, 2N3241, 2N3261, 2N3512, 2N3932, 2N3933, 2N4068, 2N4069, 2N4074, 2N4259, 2N4390, 2N5180, 2N5183, 2N5184, 2N5185, 2N5186, 2N5187, 2N5188.
Germanium: 2N388, 2N398, 2N404, 2N1302, 2N1303, 2N1304, 2N1305, 2N1306, 2N1307, 2N1308, 2N1309.
40,000 Series: 40231, 40232, 30233, 40234, 40235, 40236, 40237, 40238, 40239, 40240, 40242, 40243, 40244, 40245, 40246, 40354, 40355, 40397, 40398, 40399, 40400, 40405, 40413, 40458, 40519.

GE Discontinues IC Manufacturing

GE has quit making their popular line of audio IC's such as the PA234, PA237, PA246, PA263. Most of these are already in short supply – for example there are no more PA237 devices to be had. Best bet for audio IC's include the Motorola MFC9020, MC1316P, RCA CA3020, CA3020A and Plessey SL403D.

The RCA devices are already hard to find, for example the popular 2N5188 and many of the 40,000 series are in short supply. In most cases, a suitable replacement device can be used so the situation isn't as bad as it first may appear. If you need help in locating replacement devices for RCA transistors or GE integrated circuits contact *Circuit Specialists Co. Box 3047, Scottsdale AZ 85257.*

SSTV SCENE

Among the notes of special interest this month is the addition of XW8AX to the SSTV ranks. Since Asia has the lowest amount of SSTV activity, I'm sure he will be quite busy handing out those 'Eyeball QSO's and instant QSL's." This, at last, makes worked all continents on SSTV a reality for us all . . . provided you can catch him. Try listening around 1200–1300 GMT Saturdays and Sundays on 14.230 kHz. You SSB DXers take note here . . . you can work anybody in Asia for an Asian QSO. We have to work a specific station and swap not only signal reports, but pictures as well. DXing Supreme, eh?

(continued on page 13)

EDITORIAL BY WAYNE GREEN

GOING THROUGH CHANNELS

One of the biggest features of FM communications is the concept of channelizing. What a difference this makes! One wonders what might happen to low band communications if we could introduce this novel concept there.

With two kHz channels in the 20 meter phone band we could have 75 sideband channels in that 150 kHz wide band. Would we have better communications this way or worse? We might have essentially 75 going roundtables during the more active hours, but the less time that each operator could talk would make it a lot easier for everyone. Or would it develop that we would have 75 channels all sounding like the CB channels? Would we have multi-kilowatts and giant beams blasting through on each of the channels, ignoring the lower powered peasants? It has worked well on two meters, perhaps it might on 20. We could try.

If we were to start with one channel on twenty meters and then gradually expand this to two, three . . . etc., perhaps we could see how we might go with channels. An FM-sideband interface which would permit a two meter repeater to work cross-band to twenty on a national channel could be a starter. Perhaps something like 14,250 kHz? This isn't a bad spot. It is a bit below the SSTV group and above most of the serious DXing. It is below the General Class band and the intensive QRM of the nets and frustrated rag chewers who operate there. Channel two could be 14,248 . . . etc.

Think of the benefits to everyone. It would, first of all, make a lot more fun for the two meter FMer, expanding his horizon to the world. It would bring FM to the attention of the low banders, whetting their interest and perhaps speeding up the swing to FM of more old timers. It would encourage more repeaters to handle the traffic and rag chewing which would develop. And if channelization helps on twenty meters, that would be the best benefit of all!

The legal problems of Techs using 20 meters by proxy have been covered in depth elsewhere.

CONTROL

The key to the question of legality of Techs being repeated out of the Tech bands lies in the matter of control. If the FCC decides that the carrier coming from a Tech station is controlling the transmitter of the repeater, then the Tech would be in control of the output carrier and would be required to be sure it was within a band his license called for.

But is the Tech carrier really in control? Let's look at that situation more carefully. Let's think a little more deeply about the word "control." Our problem here is one of a lack of definition . . . one where Techs might have one definition and the Commission another.

Perhaps we can clear things a bit by drawing a parallel. Let's take the case of an Advanced Class station on 20 meters. Sideband, of course. As normally operated this station used VOX (voice on transmit), a gadget which turns the transmitter on when someone speaks into the mike. When a visitor speaks over this station his voice turns on the transmitter, even though he has no amateur license at all. This is quite legal as long as the licensed amateur is present and is "in control" of the station . . . which means in essence that he can turn off the station if something goes wrong. Control then is the ability to turn a transmitter on or off in an emergency and not the routine turning on and off of the transmitter.

This is exactly the situation we have with repeaters. While the carrier from a Tech does indeed actuate the repeater transmitter, this does not interfere with overall control by the licensee of the repeater. Control of a repeater may be via 450 MHz link, by phone line, or other accepted means, but this is the control and the FCC will have to make sweeping changes in their interpretations of the rules before they can prevent repeaters from relaying Techs into the General parts of the two meter band . . . or even into the Extra parts of 75 meters!

WHAT IS AM?

Those readers who are theory minded may be able to commiserate with me on the problem of amplitude modulation. I've read a lot about it down through the years and felt there must be something basically dense about me since none of the explanations made sense. Why, if we are varying the amplitude of a transmitted carrier, does the carrier not vary in amplitude? And those sidebands, what are they and where did they come from?

Pity a chap named Robinson out in Michigan who has managed to come up with a real amplitude modulated carrier and has found that he has patent problems because everyone, including the Patent Office thought that "amplitude modulation" resulted in the carrier varying in amplitude.

The process that we have always considered as amplitude modulation was actually a high level mixing of audio and radio frequencies, resulting, as always, in mixers, in the sum and difference of the two mixed frequencies plus the two original frequencies.

I don't suppose you really want to be bothered with an attack of theory like that, but the concept hit me and I thought I would pass it along.

NORTHEASTERN REPEATER MEETING

Representatives of several of the repeaters in the New York and New Jersey areas got together in early January to hash out problems of repeater interference and, to the pleasure of all, came to agreements. This is certainly a very welcome step ahead.

The basic agreement was for repeaters to shift to 600 kHz spacing and thus bring about the orderly growth of repeater use on two meters. A full report on the meeting will eventually filter through, but the word is that WA2SUR in New York will shift from 19–73 to 13–73, that WA2UWR in Paramus will change from 28–79 to 19–79, WA2YYQ on Staten Island will go from 25–88 to 28–88, WA1KGK in Trumbull will change from 22–76 to 16–76, WA1KGD in New Haven from 11–61 to 01–61, and so on. It is possible that K1MNS in Derry NH will go from 25–76 to 25–85, but this leaves a question about WA1KFX which was 31–88 and was apparently being set up on 25–85 as soon as power was restored on Mt. Snow . . . it would clobber MNS. WA1JTB in Greenwich is still in doubt too, but may go 31–91.

This rash of agreements will undoubtedly bring about even more with K1FFK expected to shift to 04–64, WA1KGS (Waltham) to 01–61, WA1KHA to 25–85 in Torrington, WA1KGQ to 19–79, etc.

The move toward a national transceive channel got a boost too,

with an agreement to go 146.52 transceive throughout the New York–New Jersey areas. The next step is to encourage manufacturers and distributors to see that all newly sold transceivers come out with this pair in them instead of the old 146.94 pair which has muddied the waters so badly in several major areas such as New York City and Chicago.

* * *

The FM scene changeth fast and it is difficult to try and keep up with events in a monthly magazine.

Saroc came and went in early January. There were more exhibitors and visitors than ever and, despite a lack of planning as far as the speaking program went, everyone had a good time. FM was the watchword, with hand units everywhere and the regular channels filled around the clock, often sounding more like CB than amateur after the frequent cocktail parties.

The Pallisades Amateur Radio Club group turned up in force and brought with them their own instant repeater (right out of the October 73, by the way) so everyone could use their weird Los Angeles crystals while visiting Las Vegas (146.61 in, 147.33 out!). This enabled all of the club members to use their mobile and hand units during their stay without changing them over to the 34–94 Nevada repeater channels.

With the idea of promoting some organization of the FM growth in the northeast, we started the Repeater Bulletin back in January. This publication is being sent free to everyone using the New England repeaters and the reaction to the first 24-page issue was universally enthusiastic. The second issue, a 32-page bulletin, is now out and the publication seems to be achieving its objective of providing a forum for discussion of development of FM in the New England area.

In line with the idea of helping New England repeater groups to coordinate, an FM Symposium was planned for February 12th. Apparently this threw some of the vested interests into panic and a swift behind the scenes effort was made to set up an FM organization which would pull the rug out from under the symposium. Rather than being dismayed at this, I think it is a good move. The objective is to set up a system of self-government and the agreements made so far are quite in line with this. There is still more to be done, obviously, and 73 will do whatever it can to help this along.

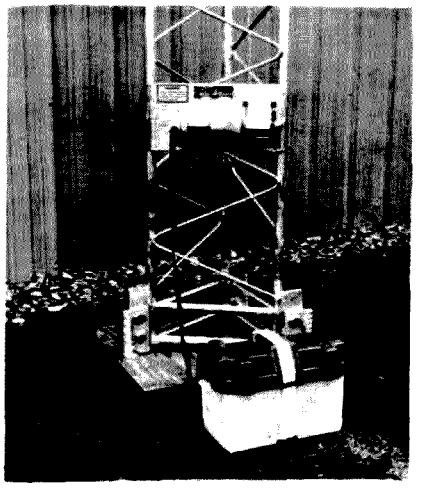
To those who are afraid that 73 or Wayne Green are going to try and take "power" away from them, I say that I seek only the power of reason. I do not want to run anything or dictate, but I do want to be heard and I want to help anyone else with ideas to be heard . . . I ask no more than that. Power all too often means running roughshod over people with ideas that differ from yours and it is this power that I dislike.

The symposium should be interesting. It will be reported in the next issue of 73. The first session of the symposium will tackle frequency synthesis and will feature a panel discussion with Ed Clegg and Andre (Vanguard Labs). Gil Boelke may also be present, if the new Bara synthesizer is completed in time.

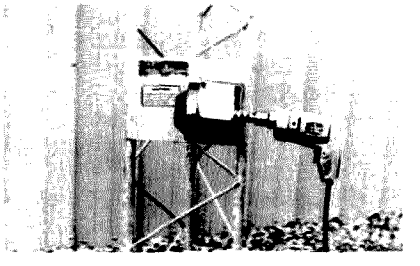
The second session will tackle needed FCC regulation and this will be reported in full to the FCC. I think we amateurs want to be self-policing and to have a strong say over our own rules. Sessions such as this should help us in this.

The third session will attempt to get the representatives of the New England repeater groups to set up a frequency board which will help new repeaters to find channels and assist present repeater groups in working toward a minimum of interference.

Following the third session will be the banquet with Jean Shepherd K2ORS as the speaker. Jean, one of hamdom's best known writers and humorists, is heard nightly over WOR, WGBH and other stations, has a book on the current best seller list, and has a television series (Jean Shepherd's America) which has been highly acclaimed. Few of us have missed the hilarious stories he has had published in Playboy, which have won him their coveted humor award for several years running.



After the banquet there will be one last technical session tackling the pros and cons of changing the current 600 kHz spacing to 1 MHz channel spacing. The arguments are formidable for 1 MHz, so it is entirely possible that the repeater representatives might opt for that on the spot. We shall see next month.



. . . W2NSD

NEW PRODUCTS

NEW WINCHES MODERNIZE TOWERS

Tri-Ex Tower Corporation of Visalia, California, has announced the release of two new electric winches for crank-up towers. The 12 volt electric reversible winch is sold with power cables; the battery in weather tight case and 110V AC battery charger are optional. It has forward and reverse speeds for raising and lowering the tower, and a level wind assembly to keep the cable from stacking. Braking is immediate, without coasting or creeping. The electric winch adds a safety feature in eliminating spinning handles, slipping clutches or exposed gears.

The TDD-100 Winch is driven by the average 3/8 in. drill. Two drive bits are furnished with the winch to be inserted into the gear train for raising and lowering. If the drill is not reversible, the short drive bit can be inserted in the opposite end of the winch to lower the load. Braking is automatic and the TDD-100, stopped at any point, will hold a load indefinitely.

Both winches are easily installed and bolt directly onto the existing tower winch mounting frame. For complete information on the new Electric Winches, write *Tri-Ex Tower Corporation, 7182 Rasmussen Ave., Visalia CA 93277.*

HAND-HELD SSB

If you do not want to go FM, here's a hand unit for the low band enthusiast, single sideband at that. The Mini-Mitter II is a crystal controlled rig that runs four watts PEP output into a fifty to seventy-two ohm load. The beauty of this unit is that a short whip antenna is available as an accessory and the unit is instantly portable for field day, emergency, or camping, or just having fun sitting under the sun in your back yard. The power level is adequate for medium range QSOs when the kilowatts are not on top of you, but that's the fun of QRP opera-

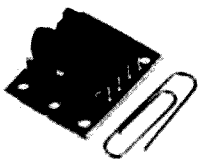
(cont. on page 8.)

More New Products

(continued from page 7)

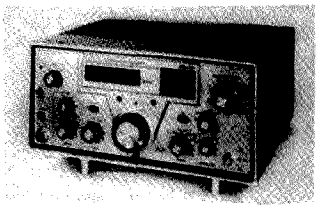
tion. The Mini-Mitter is available as a kit for $150. Popular frequencies of 3995, 7215, or 7255 are available, and the rig can be changed according to instructions in the manual. For complete information, write to *American States Electronics, 1074 Wentworth St., Mountain View CA 94040.*

MINIATURE BUZZER



Miniature is the word, too . . . 7/8" long, 5/8" wide, and 3/8" thick is small. The output is good and loud, though, despite its small size to permit it to be used for code practice for a good sized room full of people. The buzzer is available in 1.5 and 12 volt dc models, with the 12-volt unit drawing only 15 mA, quite low enough to be operated by a transistor gate for paging or warning applications. The quarter ounce unit is small and light enough for uses in hand transceivers.

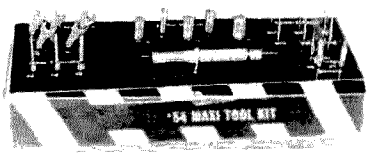
The Model GA-100 buzzer is solid state and has no moving contacts, therefore there is no arcing and no electrical or rf noise generated as with most buzzer units which act as miniature spark transmitters.



The output tone runs around 400 Hz, about right for code practice or paging uses.

The buzzer is being marketed by *Projects Unlimited, Box 1426 Northridge, Dayton OH 45414,* and sells for $5.95 through parts distributors.

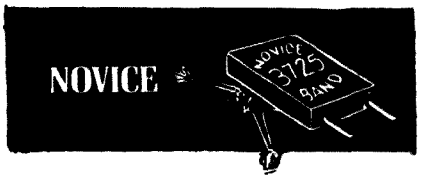
MINIATURE TONE ENCODER



Alpha Electronic Services Inc. has announced its new hybrid tone encoder Model ST-85J which is designed for use in all two-way radio communication equipment including portable and hand held units. This compact, easily installed unit provides an economical method of controlling base stations, repeater stations or special functions. Current requirement is less than 4 mA at 12.6V. Composed of two thick film chips, one containing the encoder circuitry and one containing the frequency determining network, the ST-85J is available with several installation kits and simple step-by-step instructions to assure easy installation in any make or model of radio, especially where space is a premium. For additional information, write *Alpha Electronic Services, Inc., 8431 Monroe Avenue, Stanton CA 90680.*

SSB TRANSCEIVER

You can be top man on any band with Sideband Engineers' SSB transceiver. This rig offers six digit frequency readout on all bands eighty through ten; that's 100 Hz direct reading, and the vfo skirt is calibrated so you can reset your rig to precisely the same frequency time after time. But that's not all. The 500 watt PEP input is sufficient for barefoot operation, and for those who want to run the full legal limit, a two kilowatt linear amplifier will soon be available. The SB-36 has a built in VOX, semi break-in CW, and separate crystal lattice filters for upper and lower sideband. These filters allow the rig to produce clean and crisp SSB audio without frequency shift when changing sidebands. (Ever try to work someone on LSB on forty in the evening? Try USB for a pleasant surprise.) Accessories include an external vfo for split frequency operation and a CW receiving filter to help you pick out the rare ones from the QRM. For more information on this amazing rig, write to *Linear Systems Inc., 220 Airport Boulevard, Watsonville CA 95076.*



SUBMINIATURE TOOL SET

Tiny multi-purpose instrument tools in a 22-piece set are now available for use on very small fasteners. Suitable for use by instrument repairmen and hobbyists the tools are designed for instrument repair and light assembly work involving very small nuts, set screws, and machine screws.

The tool set, Mini Kit No. 54, contains six jeweler's type screwdrivers, two cross-recessed Phillips-type drivers, five open-end wrenches, three Allen-hex type wrenches, five socket wrenches, a marking scribe, and a knurled, chuck-type handle for positive gripping. The blades are interchangeable, and all are made of hardened, tempered nickel-plated tool steel. The complete set is packaged in a clear plastic box for easy use and convenient storage. It is priced at $14.50, postage paid.

For further information, contact *Jensen Tools and Alloys, 4117 N. 44th St., Phoenix AZ 85018.*

Dear Sirs:

I have been trying to receive DX stations and stations on the West Coast. However, I have not had very much luck. Please tell me the times during which I can work these stations, and the bands where they usually are found. I would appreciate it very much.

Sincerely,
Roger W. Miller WN1OGZ
Bantam CT

Dear Roger,

Well, I guess you have found that it really takes a lot of digging to get the DX. Although I am not as much a DXer as some, let me share some hints I have worked out and a few of those from people more successful than I.

First, listen a lot. There's an old adage that says God gave us one mouth and two ears to be used in that ratio. It's good advice. Very few DX stations will come back to long CQs, and the rare ones usually do not come back to me then I call CQ DX. That is what I have found. Listen a lot in the General portions of the bands to get an idea about what frequencies are most active and open. Use a good receiver with a good antenna; a ten foot long-wire just will not make it for consistently good results. A set of earphones is a good investment, especially if you intend to do any late night listening, and even more important if your shack is in your bedroom.

Second, choose your frequency carefully. Fifteen seems to be going out and forty and eighty are coming in due to the changing sunspot cycle. Now that the sun is sending out less radiation that ionizes our atmosphere, higher frequency signals (e.g., fifteen meters) are not being reflected to distant locations. The last time the sunspots changed around like they are doing now (they work in eleven year cycles), I found that winter months meant forty was *my* best band. A friend of mine consistently worked Russians on eighty. A second friend used to listen intently on ten meters for the freak band opening and he worked Africans. It is only fair to tell you that all of this was in the early morning, around six or seven. Others I know preferred the late, late night, after the TV stations closed down. Their results were similar. By the way, my best direction was South America.

At night, you have probably found that it is extremely hard to pick out another ham on the forty meter band. It seems that foreign broadcast sta-

VERMONT QSO PARTY

All amateurs are invited to participate in the Vermont QSO Party sponsored by the Central Vermont Amateur Radio Club. Vermonters are urged to work as many out-of-state stations as possible so that those interested can earn credit toward WAS, WANE, W-VT and USA-CA Awards.

1. TIME: Saturday, Feb. 26, 2300 GMT (6 P.M. EST) to Monday, Feb. 28, 0300 GMT (10 P.M. Sunday)

2. SCORING:

Vermont stations 1 point per contact and multiply by the number of ARRL sections and foreign countries worked.

Outside stations 3 points per Vermont station worked and multiply total by the number of Vermont counties worked on each band.

QSO credit with the same station on different bands and/or modes will be given.

3. AWARDS:

(A) Certificates will be awarded to the highest scoring stations in each ARRL section.

(B) To the highest scoring station outside of Vermont, a trophy will be awarded.

(C) To the highest scoring station in Vermont, a trophy will be awarded.

(D) To the 2nd, 3rd, and 4th highest scoring stations in Vermont a special certificate will be awarded.

(E) The W-VT (Worked Vermont) Certificate will be awarded to stations working 13 out of Vermont's 14 counties, provided the station has not previously been issued this award.

(F) Special certificate for multi-operator stations.

4. EXCHANGE: Vermont stations send number of QSO, RS(T), and county. Others send QSO number, RS(T) and ARRL section.

5. GENERAL CALL: For non-Vermont stations: "CQ VT" or "CQ VT QSO Party". For Vermont stations "DE VT" or "Vermont Calling".

6. LOGS (or facsimiles): Postmarked *no later than March 31* should be sent to CVARC care Ansel R. Carnahan, P.O. Box 3, Montpelier VT 05602.

7. Stations sending a S.A.S.E. will receive a copy of the results.

Vermont stations are urged to be active and to promptly QSL all stations worked.

* * *

The Fifth Annual OOTC QSO Party will be held from Tuesday, March 14 through Thursday, March 16, starting and ending times both 2300 GMT. Scoring for Canadian and U.S. amateurs is one point per contact per band. Contacts with stations outside of U.S. and Canada count three points per contact per band (KH6 and KL7 count as DX). Foreign stations earn one point per contact per band for QSOs within their own country. Five points are earned for contacts outside of their own country. All modes are allowed, but only one contact per station per band may be scored. Multipliers: Count each state, province, or country as one multiplier per band (DC is counted as a state). Logs must be in GMT, and sent to G. MacConomy, W6BUK, Space 45, 36770 Florida Ave., Hemet CA 92343 no later than April 20.

* * *

On March 5, the Tri-County ARC will hold its Mid-Winter SwapFest at the National Guard Armory in Whitewater WI. The all-day affair will be held indoors and there will be lots of free parking. Tickets are one dollar in advance or one-fifty at the door (an extra buck reserves a display table). Talk-in will be on 3985 kHz. Contact WB9DWG. for tickets and info. His address is RR #4, Box 235, Fort Atkinson WI 53538. Snow-date is March 12.

tions clutter up the whole place. It is true that much of this is illegal operation on the part of other nations, but the spread of 7.0 MHz to 7.3 MHz is not exclusively ham throughout the world. Some countries are broadcasting legally in that range because it is legal for them to do so in their part of the world. They too are supposed to abide by the rule that they should cause no interference to other services. But that doesn't help us very much at all. I'm going to guess and say you go to school. If so, get up an hour earlier (that means going to bed earlier; don't I sound like your parents?). Get up and listen on forty or eight to hear what is on. It's often different from the night. Try three in the morning for more variety. Get the picture? The fewer people there are to crowd the band, the easier it will be to work the few who are there.

What I'm getting at is to listen around the bands and find what is best for you; time, frequency, direction the antenna works best, the weather.

As to transmitting, they'll rarely hear you if you are in the middle of the band. It seems like every Novice has crystals for the middle of the band and uses them all the time. Get closer to the band edges. The closer you can get to the station you want, the more likely he is to hear you. This is a good case for owning many crystals. "Impossible", you say. "Even if the price were halved." MicroComm makes a variable crystal oscillator that is like a VFO; it allows you to swoosh right on top of the station you want to call. Of course all swooshing is done with the transmitter in standby. They advertise in 73, and they only ask forty dollars for the device. That's the price of about ten crystals and this unit works on eighty and forty. A worthwhile investment, I'd say.

As you listen and work around, you'll notice that the bands can change right out from under you. Learn what times the west coast comes in. What time does South America roll in? Does the band change its direction in a clockwise or counter-clockwise rotation? Make graphs or notes in your log so you will be able to tell just what the bands were like when you look through your log thirty years from now.

The key is keen listening. If you can't hear them, you can't work them.

73,

Eric

(From the West Coast DX Bulletin)

If construction of a weather station on the island of Bouvet proceeds as hoped, the call prefix 3YØ may be heard. A ZS1 is being mentioned as the one who will be the operator there. The Spratley Island expedition was not carried through due to unfavorable landing conditions. It appears that the ITU never authorized the use of the call 1S1A and prefers that it not be appropriated. It has been indicated that in such instances where there is no proper call sign that just the call of the operator with the geographical location as a suffix should be given. In this instance, the call might have been WA5VTU/Spratley.

From the Pacific area, the Fijis may change their VR2 prefix for a 3D2, and it seems there is a 3D2 being heard on 20. From Nauru, the C2Ø prefix may only be used on holidays, such as January first. Does anybody know when holidays occur on Nauru? JD6 will be the prefix for Okinawa to replace the KR8 issued by the vacating authorities. KJ6BZ, on most days at 21,285 at 2200Z, has been looking

(continued on page 10)

DX FOOTNOTES

(continued from page 9)

for the Midwest and East Coast. He will return to Johnston on March 2. VR5FX is still very active from Tonga, usually found on 20 CW in the 14,235 to 14,250 kHz range.

Watch for Karl, VE8RA, as he plans to operate from Wallis (FW8) from March 14–22, and New Caledonia (FK8) from March 22–27, possibly until April 3 depending on activity. All bands will be used from each location. When calling, indicate whether you are transceive. Karl will also listen in the General portions of the bands and QSLs will be handled by VE7BWG.

From a remote plantation in Haiti, HH9DL has been heard at 14,220 kHz around 2250Z. Don, the only true HH9 in residence, is also reported as showing up regularly on forty at 7250 kHz at 1230–1300Z. His QTH is at Fort Liberte, thirty miles west of Cap Haitien.

SU1IM and his daughter Dr. Moona, SU1MI, are the only Egyptians currently active. Ibrahim has been trying to get through to the West Coast around 1500Z and after, usually operating in the 14,040–14,060 slot. K6KA has an eyeball sked with SU1IM in Cairo this April. Hopefully they'll make it.

And from the Far East, A5A to A5Z has been assigned to Bhutan. Yontan's SSB signal was last reported as not too strong. He may try the 1600–1700 time period on CW looking for the 6's and 7's. Look for him around 14,045, but he was recently heard at 14,301 at 1200Z.

An ARRL Directors' Letter informs us that a third party agreement has been signed between Trinidad and Tobago and the United States. Since this is the first instance of "British" willingness to allow its amateurs to handle third party traffic, hopefully it is a portent of similar things to come.

DX NEWS

If a direct QSL address is not otherwise available, QSL's for K and W/TF amateurs operating in Iceland should be sent to Keflavik Amateur Radio Organization, Box 44, FPO New York NY 09571.

Box 1058 Reykjavik is appropriate for QSL'ing to Icelandic nationals (TF--) only.

LETTERS

ou goons don't ever proofr
l asy
bu nch f ro ks
you ignored my comments In
I insist that you print ev

I have been very pleased with the good service in changing my address and getting me my 73 magazines. I subscribe to two other electronic magazines, and yours is the only one I have been receiving since I came to N.Z. four months ago.

Ham radio over here is a little different. These guys are homebrew artists! They are known as "Make-do" artists and it is certainly true! I feel conspicuous with all my factory-built gear, and will have to start building again. There is a spirit among the hams and at radio club meetings that I remember in the states back in the 30's . . . friendliness and "shirt off my back" attitudes, etc. They have certainly been most helpful to me. I obtained my reciprocal call with a minimum of red tape and now have K4IF/ZL1BME for a call. I will sit the regular exam and then will have just a ZL call. (This because I have immigrated permanently.)

H. D. Woertendyke
Blenheim NZ

I have my end of the ten meter link in operation and tied into my remote on Harness Mountain. As it now stands, 94 signals heard on my mountain are retransmitted on 29.680 and incoming signals are retransmitted out on 34. Subject, of course, to my control. Anyone listening on 29.680 will hear the Pacific Northwest repeaters along with the "auto-ID." This auto ID consists of a female sexy voice who every 3 minutes says: "This is the W7DXX DX repeater on Harness Mountain in southern Oregon." When the repeater (the 10 meter end) is activated from another 10 meter signal the auto ID sends a CW ID (de W7DXX/DX RPT).

Until you get your end going or someone who reads your comments in this month's 73 gets his going on 29.680 there will be no DX. However, anyone with receive capabilities should hear the Pacific Northwest when 10 is open.

If you wish, give me a call on SSB on 10 and we can coordinate. You pick the frequency and time.

Take a listen to 29.680 for the link and let me know when you are ready to go.

Keith E. Lamonica W7DXX
Springfield OR

Keith's repeater expands the range of the two meter enthusiast many hundreds of times. Can you envision coast-to-coast contacts with a little hand-held unit with a nineteen-inch whip? Think of it.

Having tried many times to learn the code and get a ticket I read with interest WB6JNI article that each letter should be sent at about 20 wpm. W3KBM also made a similar editorial Nov. 1970. Once I had such a code instructor and it helped but he was only substituting.

Could you tell me if any code "tapes" are available that are "skip" recorded? If none are available maybe a reader would be able to make me a "skip" tape of K9AAU "A New System for Learning Morse Code" Apr. 1969.

Ramer W. Streed
3004 So. West Avenue
Sioux Falls SD 57105

Off-hand, we don't know of any such tapes. Perhaps one of our readers can help out here. –E.

I would like to apply for your Real Rag Chewers Award. I have completed the requirements set forth in your Sept. '71 issue.

The calls of the stations involved, WB9EMV (me) and WB9CKG The operators' names are WB9EMV Mark Miller, and WB9CKG Richard Leiterman. The times were from 2300 GMT, December 21st, to 0500 GMT, December 22. We used the 40 meter band with the modes of CW, SSB, AM.

I have been a subscriber to 73 ever since I was a beginning Novice (my only ham mag.). I enjoy it very much and am glad you came out with these fine awards for us without big beams or kilowatts.

Mark Miller
Wauwatosa WI

Other awards available are the WAZP (Worked All Zones Promised). This is a pledge to do just that – a promise to work all 40 zones. The Certificate Haters Club is a solemn oath to hate this and any other certificates that might ever be earned. Less tongue-in-cheek awards that recognize real operating accomplishments include the WAAS, Worked Almost All States. Everyone knows that the fiftieth state is the hardest to work, and this award recognizes the achievement of 98% of the intended goal. And an easy chore for the DXer might be to work ten countries, but the Novice (and some Generals too) has to really work hard to get that many. The DX Decade Club is a large group of DXers who do not make DXing their chief aim. Endorsements are available too. To receive the CHC or WAZP, send a signed statement

swearing to abide by the appropriate conditions. For RRCC, send the calls of the stations involved, names of the ops, and times (GMT) beginning and ending the QSO. For DXDC and WAAS, send the QSLs (package them carefully and include return postage sufficient for first class mail) so we can send them back to you. Naturally, all awards cost one dollar and you can send for them in care of the Novice Editor, 73 Magazine, Peterborough NH 03458.

Well you finally found a type size so small that it cannot be read. I refer to the lack of an index for the year of 1971. Only you would print the December issue without the yearly index.

W. C. Warman W1KVK
S. Burlington VT

The yearly index was postponed because we are planning a complete index from October 1960 to December 1971. All in due time.
Eric

Here's my $6 for another year. I think 73 is the best by far of all the ham magazines. I enjoy it very much and really look forward to the next issue each month.

Another note is on the ads in 73. I really enjoy reading the ads and I like them spread throughout the magazine. Your ads just seem to be more attractive than in the other magazines and I make a point to read all of them. I really like the color ads and especially liked the Regency ad in October.

So keep up the good work and when all the other magazines are gone 73 will still be on top in my book.

Larry Standlee WA5NTF

Our faces are blushing.

I just got my Dec. issue of 73 (my 3 year renewal was just sent in). Like you, I was disappointed in the Dec. issue. I sure hope you get ads to build up 73, also more good articles.

More power from 6146 was a disappointment to me. It's like taking a stock car designed for average 60–65 mph and driving it 95–100 way past design. I like to run things with reserve.

On the subject of interesting QSOs I hardly even run into anyone I wish to sign with quickly. Most of them I look forward to talking to again, I just don't get on as much as I would like.

Orville Gulseth W5PGG
Clarksdale MS

Several months back I bought a copy of your "Amateur Radio Extra-Class License Study Guide." After which time I practically lived with it until taking the Extra examination November 16. Upon completion of it I was told I "almost" passed it, meaning I didn't. Back to the drawing board and the study guide and a return bout on December 14 which proved an overwhelming success, and believe me, I owe 95% of it to you and your genius (genii?) minds for compiling and publishing such a helpful Study Guide. It is most comprehensive in scope and information obtained from it enabled me to understand subject matter that had hitherto been way over my head.

My first try at the examination, and failure, was by no means the fault of the Study Guide. I just had not had enough practical experience with a lot of the subject matter to envision the answers they wanted. The examination showed me where I had spent a lot of time studying subjects that they weren't interested in and by the same token showed me what to expect the second time around.

In general, this is to write my appreciation for making this book available to Hamdon, which has been sorely in need of something like this. It will surely remain a valuable item in my library and I hope other hams feel the same. Without reservation, the genius who put this Guide together has no equal, "par excellence!"

Ross E. Hicks, Jr. W5LPF
Arlington TX 76010

You're welcome, you're welcome. This letter is typical of those we receive in reference to our Study Guides – Novice, General, Advanced, and Extra.

I have received about 100 letters from readers on the "Plug-in Solid-State Vibrator Eliminator" which you have reprinted in the Jan. 72 issue. Most of them ask for additional information and errors if any. Here are the most common questions and answers.

The original circuit shows resistors R1 and R2 and being 44 and 4.4Ω. (A) This was a printing error and should read 4.4Ω each. However the value required may be between 3.3 to 5Ω.

What type transistors did you use? (A) I used Two type 2N443 stud style transistors.

Is there an American replacement for the toroid? (A) To my knowledge there is no American replacement. The Hammond Model 511E is manufactured in Canada by the Hammond Manufacturing Company, Guelph, Ontario. H owever it cannot be purchased direct but through most of the electronic jobbers here.

Do you recommend any other changes? (A) I would install a choke and filter in the 12 volt line to prevent the 200 Hz from getting out on 12 volt line.

Since there. are probably many more readers who might be interested, I have sent this info which should be helpful.

Vern Epp VE7ABK
Nelson BC

I echo your plea for an article on a synthesizer. I am amazed that some of the leaders in solid state devices and accessories haven't seen the need that exists. How about a nice kit? Also how about an article on adding a limiter/discriminator/squelch to AM receivers? Take your old communications receiver, hang an FM receiving adapter on it next to a converter, wire a meter in the discriminator and maybe even a deviation meter, and you have a highly useful instrument that can do quadruple duty.

I'm not smart enough to design these things, but I sure can see a need for them.

Re your suggestion on a repeater contest. Sometimes you have good ideas. This time you didn't. A contest would not be in keeping with the type of operation most repeater users desire. I love contest work, but not the screaming and backstabbing that would go on for the inputs of the machines.

Frank J. Derfler Jr. K9KIC/1

I have been a licensed amateur for 13 years, an ARRL member for the last six consecutive years (I had to join because I could not longer buy the QST over the counter). I have been an IEEE member going on my third year. So you see I do know something about both organizations.

I agree with Mr. Chapin in his Guest Editorial in Jan. 1972 issue of 73. I too feel there is a need to reorganize the organizational structure of the ARRL and update the by-laws and constitution using the IEEE as a pattern.

In Mr. Chapin's editorial only four classes of membership in the IEEE were listed, but there are five grades of membership. The associate member grade was not listed. The grades of membership in the IEEE are (1) Fellow – (2) Senior Member – (3) Member – (4) Associate and (5) Student.

Frederick R. Washburn WA6FJJ
Los Angeles CA

About two months ago I bought a Tempo One w/ac supply from Henry Radio in L.A. In the order I pointed out that my decision was based solely on an ad in 73 Mag.

I like this rig. I had not planned a purchase of this size this year, but the family has grown and left home so funds are available.

This is my first SSB transceiver. So with limited background and experience in this area, I still like it. Using dipoles, if I can hear them, I can work them.

The other night at 7.251 MHz there was a fellow in Ecuador working a U.S. station. Guess what happened? One of our friendly, courteous hams loads up right on freq; 1st the xmttr, then the linear. He wiped out everything. Why can't these people load up a few kHz away and then come on freq?

R. W. Yerbury
Dugway UT

For ten dollars, a person can obtain a dummy load and use it. This would end the headaches of thousands of hams who listen and complain of QRM. It would also keep them from being headaches.

E.

(continued on page 12)

LETTERS CONT.

Tnx for making the DXDC award available; now I have something to shoot for. The following list shows what DX I've worked, and in what order: VE, KL7, JR, LU, OH, TI, KC4, XE, KH6, KZ5, KV4, ZL, VK, KG6, PJ9, and UKØ. The last 4 were in the DX contest (CW, of course). Please don't lose these cards, because I already feel sick about giving them to the post office, hi!

Larry Des Jardin WB6KMW
San Andreas CA

The P.O. got them here all right. They are pretty dependable. The DXDC award is available to all who send proof of two-way QSO's with ten or more foreign countries (and a buck and return postage). Novices, especially might be interested in this award.

My recent QSO with W2NSD Mobile 146.94 direct on 1/3/72 has led me to look into 73 magazine. I discovered a magazine I thoroughly enjoy, just as much as talking to Wayne.

Donn Watson WA2REH/1
Boston MA

You would be interested to know how other Ham publications are rated in this country. I have recently acquired a set of CQ for 1970 and could not find a single useful article. The RTTY column, which used to be one of their regular features, is gone, and there is little else of interest to us in India. The U.S. Library here donated to our club a set of QST for 1970. This bunch had a few articles of interest, but nothing comparable to the articles you run. You might like to know that while no one at Madras subscribes to CQ or QST, my copy of 73 is read by no less than 4 ham families, three of which contain two ticket-holders, in effect a readership of seven.

Let me wish you a bright and prosperous 1972.

M. V. Chauhan
Madras, India

Just had an idea for a ten-minute timer when my daughter's alarm clock broke and I was asked to repair it. Being a ham I noticed the SNOOZE ALARM lasted ten minutes. After five years of thinking, actually about three seconds, it occurred to me that this would make a perfect ten minute alarm for the ham to announce his call and how can you beat that for $2.98.

All that has to be done is disable the regular 12-hour alarm (simple upon examination) and whenever you want the ten-minute timer to work, just pull out the alarm set lever and push down the Snooze button. Ten minutes later the thing can blow up Boulder Dam, turn on your tape recorder, announcing a station break and your call letters. If you don't hit the Snooze button pretty soon it will start the first bars of "Dixie" and end up with "Who Got My Roller Skates." At least it will go off every ten minutes every time you hit the Snooze button.

You can buy a lot of beer or even a vari-coupler and a 201A for the money you save while making the FCC happy.

Clyde A. Welch WA4VKB
Anderson SC

Amateur radio allows a wide variety of operating methods and activities, but there is one type of operation I would like to engage in but cannot – I would like to talk to my wife while I am driving around in the car. Since the chances of her ever getting a license are pretty slim, the best solution seems to be either CB or a repeater with autopatch.

However, after reading the section of your editorial in the January issue about the advantages of using duplex on 220 MHz, another possibility has occurred to me. Why not remotely control the home station with the mobile transmitter? Then the xyl could talk through the home station.

This could be accomplished very easily if duplex were used. A low frequency remote control signal could be transmitted from the mobile along with the voice transmission to simultaneously turn on the home transmitter, activate the station identification circuits and signal the xyl. Each user of the system would have a different remote control signal.

The xyl would operate a microphone switch that would control the modulation of the carrier. This would comply with the rules since they require that only the carrier be turned on and off by a licensed operator. The station would be identified automatically in a manner similar to that used by repeaters.

Full duplex is not required. The repeater would have two separate receivers, but the combined receiver outputs could modulate only one transmitter. This would reduce the complexity and expense of the system and still allow one person to break the other. Most of the time, only one person will be talking at a time anyway. Another advantage is that calling will be simplified since everyone will be listening to the same frequency.

I don't see anything illegal about remotely controlling the home transmitter and operating it in this manner. The main FCC problem would seem to be in obtaining permission to remotely control the home station from the mobile.

I wonder if other readers think this type of operation is legal, possible and practical.

Roy E. Gould W5PAG
4748 DeBeers Drive
El Paso TX 79924

Note in the latest Callbook that New Hampshire is dropping in ham population as is the general count. Hmmm.

Missed the Revoked License box in the last issue. Watch the FCC releases for a bunch from the west coast. Some of them have been jamming WCARS and other communications on 40 and 80, and who knows what all else. One of them said he'd be on the air (just far enough away to splatter on the freq) until someone came by and took his ticket off the wall. Looks like somebody did! They nabbed a kid in Vegas who threatened to fight the president of the net if he showed up in town; as well as the goon who sounded like a pig.

Paul Schuett WA6CPP
Lodi CA

Hallelujah! Congratulations to those who helped rid the air of some inconsiderate ones. Every day we get letters about noise, QRM, and intentional jamming. It may seem like the Golden Rule is outdated and we need force to accomplish the same goals.

But for each bad news letter, we get ten like the following:

Fer the skinny blonde wat sends them 'elp notes from the dunjun. Don't wurry Luv, 'elp is on the way. I just give yore boss sum munny fer that pitchur mikin' book so I can git mi camera going like 'arry Bloggs. 'E blots out chanel 24 and 14 an I wont sum too so pik we out a good wun and if there's any left over send me some of them Mat Dillons an Festuses u got in the cellar. Tell yore boss 'es got a gud thing goin fur us 'ams wot can reed an rite an make things. So don't sen enymore of them 'elp notes. My old lady don't like it and sets the dorg to bitin' me w'ere I use most fer oporatin' my geer w'en it's in vox. An my cher don't 'ave no cushin. An tell Big Ears 'e ort to go fer ARL direktur an git us sum sence out of Charlie wots givin' away our bands. Don't fergit to send mi TV book kwik.

WA8QXU

Any activity on 10 meters FM? What does FCC think of 2 meters to 10 meter repeaters (or vice versa?) Anyone trying it successfully?

Barry Foote K1BTF
Framingham MA

Yes, there is quite a bit of activity on 29.6 MHz, particularly with low power rigs. On 29.68 MHz there are a growing number of repeater links to two meters. W7DXX seems to be pioneering this, though other repeater groups are reported getting into the action. Look for WA1KGS in Waltham to be linked to 29.68 soon . . . and others. It won't be long before two meter groups will be in contact with each other via 29.68 links . . . and, as W7DXX asks, how long will it be before someone driving in San Diego is talking with someone in Munich? Not long! DXX has already been pioneering some 20m links and recently the two meter gang had a chance to work UAØZAR via the repeater.

Due to my future husband, WA4GPJ, I have become an avid fan of 73 and amateur radio. I really enjoy 73 and although I don't understand all the technical articles, some of them are actually sinking in!

I have copies of every 73 from August 1970 through September 1971 in which you published a series of articles on the General Class License. Unfortunately I don't have a copy of July 1970 which contains the beginning article. Is there any possibility of getting a copy of General Class License Part I? The articles are well done and the progress is logical *and* simple. So many of the License Guides assume that one knows a lot of technical knowledge.

It would also be great if you could print articles for XYL's who could enjoy their husbands hobby instead of being a "Ham widow." I am delighted that Jerry is urging me to get my ham license. In fact, for Christmas he gave me a code key and a code oscillator, all rigged up and ready for me to operate. What more unusual Christmas gift could a future XYL get? By the way, I found the code very easy, considering the fear I had before getting started on it. Could you compare it to going to the dentist – "The I-know-it-is-going-to-hurt bit?"

Again, I really enjoy 73 and especially your editorials and humor that appears in the oddest places. You might say I think that 73 is terrific.

Ann Largent
Richmond VA

Ann, all the best to you and Jerry. Your missing copy is on the way with our blessings. The number of YL and XYL articles we print is about proportionate to the number we receive; maybe you will share with us your experiences after the big day. By the way, I read of another ham who gave his fiancee a code practice oscillator in kit form and made her build it in front of him. In comparison, Jerry sounds like a pretty good guy.

I reread your December editorial for the second time after letting it sink in for a couple of weeks or so.

I guess you could consider me a DX'er of sorts, or a rag chewer of sorts, or one who really cares about the chap on the other end, thousands of miles away. I have confirmations for DXCC at 241 and I don't really feel it is all that important to get 242 unless it comes easily.

I have operated from "CT1" and I also hold G5AUP in U.K. When I'm in this country I like to work the boys in Europe and around the world. When in Europe I like to work back this way. It's nice to work Father Moran (9N1MN) from NJ, but it's fun shaking him up from my London location, too. Why? Because he is concerned; he remembers about you, your friends, etc. Something personal, you see, is the key.

You won't get rid of the phone-patch gentlemen in the rare DX part of the band until you educate them as well as respect them on their part of the band. Sort of a gentleman's agreement you might way.

Now let's get down to the real biz of making a meaningful QSO.

It is important to really listen to what the other fellow or lass has to say. Don't be afraid to comment and above all have something to say, not just rst, QTH & name. Find out if he makes wine for a hobby or watches mini skirts. Judging by his accent you might ask if he is possibly from a different part of the world. What can you find in common with the other op? Follow this up if it was a good chat and make a file card on him. Next time ask him how his wife and kids are. What a surprise for him that you not only knew his name, but you knew his family, too. It takes hard work to acquire this type of feel for things. It will pay off tenfold, I assure you.

I keep track of over 3,000 people outside of the USA and I assure you it doesn't take me more than ten seconds to know my man or woman at the other end of the DX band on either CW or SSB, 10m or 16m.

I don't think I have anything special going for me except I don't make it a practice of asking for a QSL with my first over – Hi.

The other day I had a 1 hour QSO with a 7Q7 on 14.255 MHz. It must have been more than a report and how's the WX. It must be frustrating for a chap who needs 7Q7 and could care less about our chatter. But for those who were kind enough to stand by and not lose their heads, it paid off, for this 7Q7 was in a good mood then.

Chances are I will be talking to him again soon and by past experience he will know where to look for me and will probably call me.

Many amateurs don't know that for each working op there may be ten listening to your QSO. Some of my new-found friends are really old friends in a way as some tell me, "I listened to you for over two years before I got my ticket" or "We like what we hear and feel we really know you."

Try to work in and around the same frequency from time to time. Get to know the people well. Check that freq. at least twice before making that "CQ Europe." They size you up quickly and they can cut you down just as fast. Try to understand what makes people tick. Do the unusual. Talk about things not related to radio. Ask him about his country and what a loaf of bread costs. How many hours of work to buy a certain item, and so on. In other words, get involved. Above all, be sincere, be helpful, speak slowly to a chap who has trouble with English. Use small words. Be patient.

I assure anyone it works. I have skeds with Europe and Africa on a regular basis, and I have had visitors from Greenland, Denmark, England,

(continued on page 14)

(SSTV Scene cont. from p. 5.)

Well, if you are still looking for African QSO's listen for ZS3B on either 14.230 or 21.340 around 1900–2100 GMT. ZS6PP also frequents 21.340, often around 1630 GMT, EL2BC should be getting his Robot gear by now also. Watch for him also on 21.340. Generally, the Europeans and Africans are leaning toward 21.340 activity with 14.230 as a secondary choice. Much activity, also, from down under (VKS and ZLS) but this'll call for the midnight oil. They generally show around 0800–0900 GMT on 14.230 (twenty is starting back its "Late Night Re-Openings" a little early this year).

We've been "looking in" lately on the Canadian SSTV net, which meets on Sundays and 2200 GMT on 14.180 kHz. Very good pictures – some real candid shots – and a lot of info exchanged. Look in some Sunday, I think you'll like it.

The year 1972 promises to be an outstanding year. The advent of 50¢ integrated circuits, $5 phase-locked loop IC's and availability of 12–16 inch P7 phosphor cathode ray tubes, should be a real boon to SSTV. WØLMD has proven his all integrated circuit, magnetically deflected monitor for over a year now. So it should be appearing in print soon.

If you can't wait, and Sid can't furnish you with a diagram, send me an SASE and I'll drop you a copy. The monitor has bandpass filters and a tunable SYNC detector circuit, which really proves itself on marginal signals. Also, this year, watch for more information on the larger screen monitors, slow scanned cameras and new ideas on flying spot scanners. And watch for Heath to come out with a nice monitor for under $250 – maybe an SB205.

The Dayton Hamvention is coming up again in late April and, as usual, much slow scan activity is planned. Many of the new ideas on SSTV were first presented at the Dayton convention, and I'm sure this year will be no exception. Everyone will bring diagrams of their "brainchild" to the SSTV booth, and many of the top SSTV'ers are usually around.

Possibly Don Miller W9NTP, will unveil his SSTV handbook there this year.

The second W.W. SSTV contest should be over by the time this appears in print, so why not drop a postcard to me giving your results and score. Results will be tabulated, and I'll report the new "Big Guns" in this column. Send along pix or tapes of interest also. I'll photograph an interesting picture or so for possible publication in this column later.

. . .K4TWJ

Caveat Emptor?

Price — $2 per 25 words for non-commercial ads; $10 per 25 words for business ventures. No display ads or agencydiscount. Include your check with order.

Deadline for ads is the 1st of the month two months prior to publication. For example: January 1st is the deadline for the March issue which will be mailed on the 10th of February.

Type copy. Phrase and punctuate exactly as you wish it to appear. No all-capital ads.

We will be the judge of suitability of ads. Our responsibility for errors extends only to printing a correct ad in a later issue.

For $1 extra we can maintain a reply box for you.

We cannot check into each advertiser, so Caveat Emptor. . .

STANDARD SRC-145, Japanese equivalent to the SRC-146 hand-held unit for 2m FM. With simplex crystals for low end of band. First certified check for $200 to Box N, 73 Magazine.

(continued from page 13)

Portugal and others. I have also done the same myself. I assure you that when you visit a foreign land and you meet your friends they will show you and your family things no regular American would usually see.

What amateur in a foreign land would put up a 60 ft crankdown, tilt-over tower with beam at his country place with wall-to-wall American gear for my use during my stay? You say, he's kidding. Not so – I will show doubters color pictures.

Would you believe a very important man in his country took time off from his important duties to be a guide for my wife and me?

Could you imagine that a gentleman in one country who said he would meet us at the airport sent two dozen red roses to our hotel because he was called away to HB9 land, but another amateur and his wife drove 50 miles during the night to be there waiting with my QSL card in his hand so I would know someone cared.

This has only been a small sample of what can happen if you let yourself be involved.

Amateur radio can do more for international good will than our State Department has over the years.

Think of it in another way. What can I do for amateur radio? How can I get involved? Is that QSL all that important? (It will come in time, anyway.)

Converting The T-278 TRANSMITTER For Two Meters

The T-278/U transmitter is a two channel crystal controlled FM transmitter. As issued, it covers 152–174 MHz with a power output of 25W. It is most commonly encountered as part of the AN/VRC-19 mobile transmitter-receiver, but is used in a wide variety of other configurations. The transmitter requires a separate power supply and controls. Normally a DY 93-G power supply is used, but there is an ac supply, PP-804/U, which is used for base station configurations.

Conversion consists of building a power supply, control circuits and a slight modification to the final amplifier tuning capacitor. Figure 1 is a schematic diagram of the power supply and control unit. The connections between the power supply and control unit and the transmitter are simplified if you remove the existing connector and use a terminal strip for the power leads. A small butch plate can then be installed to mount two BNC connectors for the antenna and receiver antenna connections.

After you complete and check out the power supply and *before* you connect it to the transmitter set the filament control so that the wiper is on the maximum resistance side. Then connect the power supply to the transmitter. Turn it on and adjust the filament control for 1.25 volts as measured at the test point.

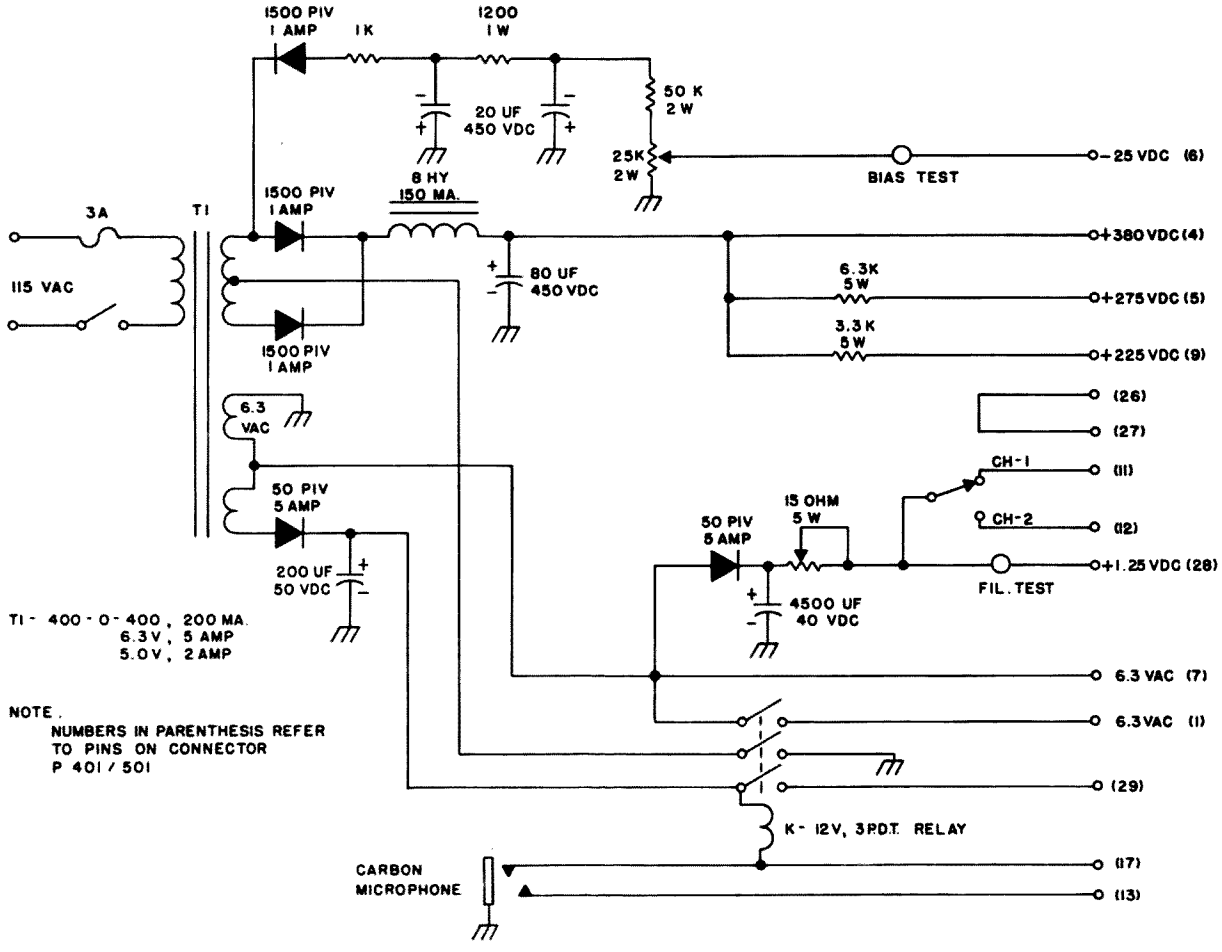

Fig. 1. Power supply and control T-278/U transmitter.

The crystal frequency is calculated by dividing the desired operating frequency by 32. Crystals should be ordered as CR-27/U type for use in an oven. Install the crystals in the oven and set capacitors C-403 and C-404 to their midpoints. For two frequency operation it will be necessary to install a second 1AD4 in the socket labeled V-402. The second frequency cannot differ by more than ±1 MHz from the main frequency.

Allow the set to warm up for at least 15 minutes before proceeding with the following alignment. This time is required for the crystal oven to stabilize. Check to insure that the crystal oven is rated at 6V.

Alignment

1. Modification of the final tank circuit. This modification is not necessary if you are going to operate above 147.5 MHz. For coverage of the entire band it is necessary to solder two 1 in. diameter thin copper disks to the existing disk capacitor. Satisfactory disks can be made from a scrap of copper or brass sheeting, or the disks found in between 88 mH loading coils can be used.

Check the operation of the sliding shorting bar. It can become erratic due to corrosion. In any event the fine pitch tuning screw is difficult to tune. The shorting bar is easily removed. Tuning is then entirely accomplished using the disk capacitor.

2. Place the test switch in the test position and the tune-operate switch in the tune position.

3. Connect the common lead of a VTVM to the chassis and plug the probe into jack J-401. Adjust Z-401 for maximum negative voltage. Detune to 90% of maximum. Move probe successively to J-402, 403 and 404 adjusting Z-402, 403 and 404 successively for maximum negative voltage. Nominal voltage at J-404 will be about 70V.

4. With the probe in J-405 (driver grid), adjust Z-405 and C-429 (driver grid tuning capacitor). There is an interaction between

these controls so repeat the procedure several times. Nominal voltage at J-405 is −55V. If a peak cannot be reached it may be necessary to solder a 5 pF padding capacitor across C-429.

5. With the probe in the final grid jack (J-406) adjust the final grid tuning capacitors and the driver plate capacitor for a maximum negative voltage.

6. Connect the VTVM across the plate current jacks. Watch out! The jacks are at plate potential. The meter reads 100 mA for each volt.

7. Connect the antenna. Adjust capacitor C-448 for minimum current. Adjust the loading capacitor and the antenna coupling for maximum current while retuning C-448 for a dip. Place the tune–operate switch in the operate position and readjust capacitor C-448 for a dip. Adjust the coupling link to limit the plate current to 150 mA (1.5V dc).

8. Disconnect the VTVM from the plate current jacks and reconnect it across the balance jacks. If the final tubes are balanced the reading will be zero. If they aren't balanced it will be necessary to adjust the final grid tuning capacitors to establish balance.

9. Place the test switch in the off position and the tune operate switch in the operate position. The set is now ready for use.

If no modulation is noted, check for a 2V dc voltage on the microphone jack. If no voltage is present, you have an early set that hasn't been modified. To modify unsolder pin one of the microphone input transformer T-401 from ground, and reconnect it to the wire going to pin 15 of the connector. This will provide dc for the carbon microphone.

In practice, the transmitter has been used for both voice and AFSK RATT. The 600Ω audio input (pin 14) is used for teletype.

Precise frequency adjustment is provided by adjusting capacitors C-403 (frequency 1) and C-404 (frequency 2). The best bet is to have the net control station talk you on frequency as you adjust these controls.

I was worried about the reliability of the 1.25V filament tubes. This turned out to be groundless as the set has been in use for over a year without a single tube failure.

Easier Conversion of Surplus Transmitter AN/ARTI-13

120V ac Power Supply

Earlier conversions of the ART-13 transmitter used the 24V dc relays from the separate dynamotor. In Fig. 1, I used no power supply relays because, like most buyers of this rig, I received no dynamotor. Two ac power supplies are controlled by primary 120V SPST switches.

The VFO supply is fixed with a voltage between 400 and 450V filtered dc. The 813 power supply is 0–3500V. A 20Ω 1W resistor added to the negative lead of the

Front view of rig shows tuning knob of C3, dynamic mike, speaker for sidetone, and tuning chart.

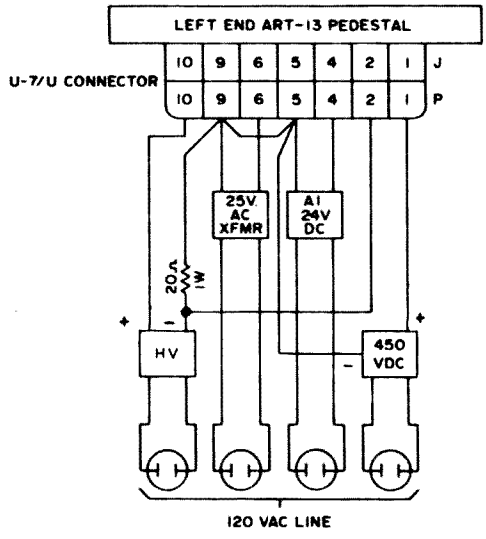

Fig. 1. Power supply arrangement. Parts are: 25V transformer: 100W Lionel Corp. (or 2 12.6V, 4A); 24V dc: Two 10A 12V dc battery chargers; 450V dc PS: 225 mA minimum, 300 mA max. (see text); HV PS: 1200V to 3000V, 200 mA (4 866 rectifiers); Resistor: 20Ω (20.1Ω) 1 to 10W (on left end).

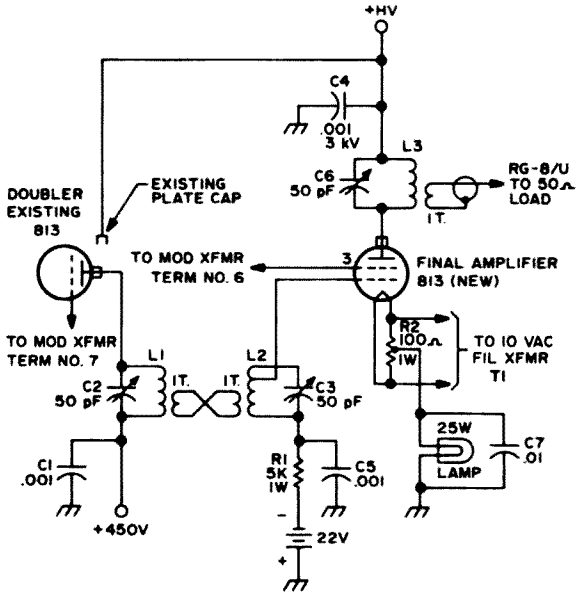

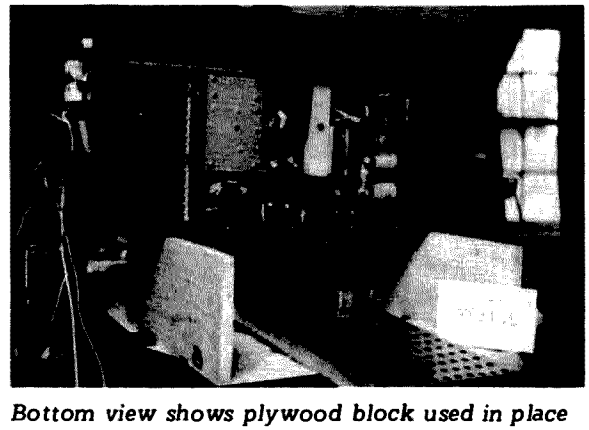

Fig. 2. Ten meter diagram. Parts include: Medium base porcelain 25W lamp holder; L2 – 4 turns No. 18 on 1¼ in. form-tap third turn; L3 – 3½ turns No. 14 on 1½ in. Hammarlund ribbed 4 pin plug-in form; T1 – transformer 10V, 4A, Zenith 7.5V and 2.5V series to add.

larger supply gives instrumentation like the original. The existing panel meter reads 0–200 mA of 813 plate current in the CW position of the emission switch. Plate volts may go to 3000 on CW. in the VOICE position, plate volts should not exceed 1250 because the plates of the 811As go pink and the percentage of modulation is lowered. The OFF position of the emission switch is not used. Neither is the cover interlock used (only 7 of the 10 pins in the U-7/U connector are used). Two 12V automotive battery chargers at 2 amps continuous duty operate the auto tune motor, etc., without filter or hum.

10 and 15 Meter Output

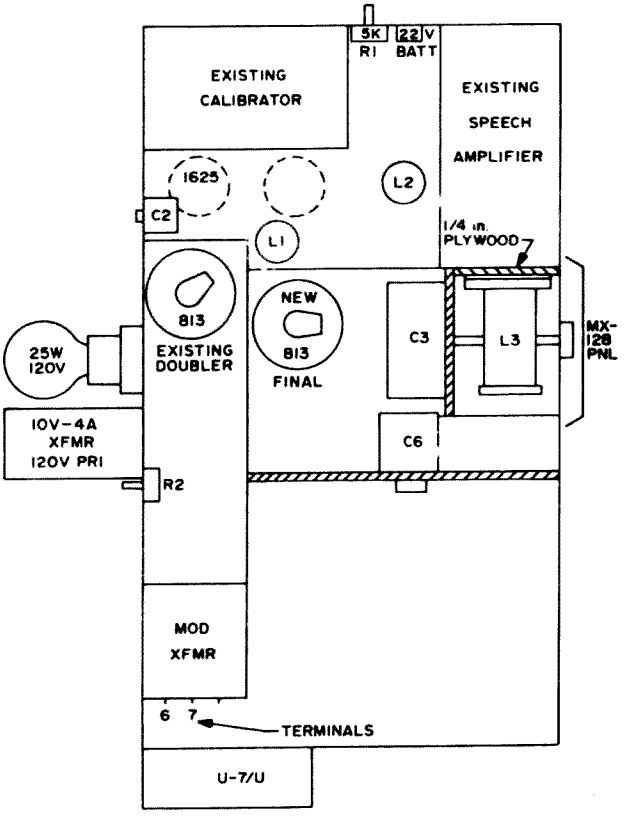
There are no soldering changes nor drilling of the basic Collins rig. The 813 tube becomes a doubler. Figure 2 shows the change of the plate circuit by changing the plate cap. Existing antenna terminal, RF ammeter and C, D, and E front panel controls are not used on 10, or 15 meters. The 813 doubler operates from the 450V power supply drawing 80 mA at resonance raising the 450V power supply current requirement to 300 mA. In the space left by removal of the LOW FREQ Oscillator, the 10 meter final is installed using a second 813. The plate current in this tube is read by the existing meter. Doubler resonance is found when the final plate current is peaked. A grid drive of 3 mA (external meter for initial tuneup) is sufficient to produce normal plate current on the 813 final. The PA GRID meter switch setting continues to read the input to the 813 doubler.

The aluminum bottom of the rig must be removed to peak the 1625 multipliers

Bottom view shows plywood block used in place of metal bracket.

for 10.5 MHz and 14.2 MHz putting the pointer into the acceptable center scale range – 8.5 mA of grid current. A single turn loop around the 29 MHz coil couples the RG-8/U coax to a 1 kW amplifier at W2ISL.

The RECEIVER terminal should be connected to the receiver antenna terminal with coax (shield goes to ground connections). The microphone used has a switch to control the entire transmitter without hash in the receiver when not transmitting. A dynamic microphone is used from a surplus MARK II 19 set (new 3 conductor shielded cable) with a PJ068 plug. Ventilation holes in the sides of the rig suit RG-8/U coax. The final tuning capacitor is mounted on ¼ in. plywood (as insulation) in the vicinity of the coil L3. The grid tuning capacitor also used plywood as insulation with an insulated flexible coupling to a 2 in. long ¼ in. shaft that passes through a *new* hole in the MX-128 panel (described in *Surplus Schematics* by Cowan Publishing Co.).



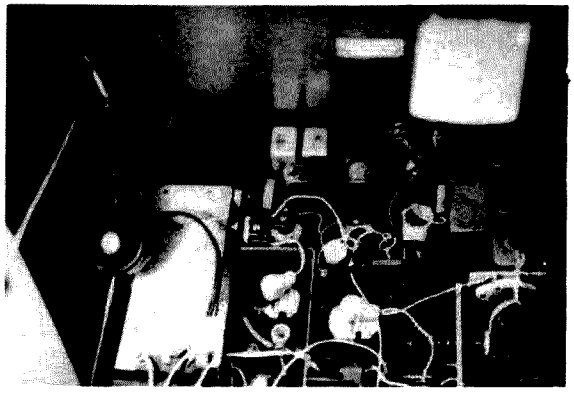


Fig. 3. 10 meter output modification.

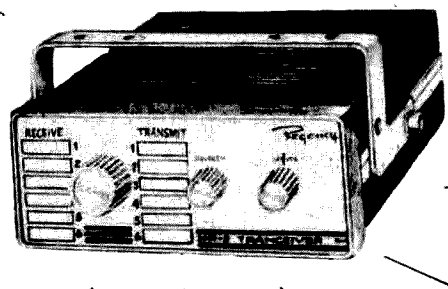

Close up top view shows coil location. L1 is 6½ (No. 14) turns on a 29/32 in. wood dowel. All three coils have generously spaced turns.

Link coupling from the doubler plate to final grid coil was used so that the doubler could be tuned to resonance at 29 MHz before and after the final was installed. An attempt to plate and screen modulate the 813 doubler was unsatisfactory. Shorting 2/3 of the turns of the final coil permits doubling in the second 813 for CW output on 6 meters. Circuit constants in the Figures are for 29 MHz because an AM carrier is feasible on 10 meters but not 15. Since the screen of the doubler 813 is not modulated, the G2 connection on terminal 6 of the 811A output transformer must be moved to terminal 7. A new insulated lead is run from terminal 6 to the screen (G2) at lug 3 of the new final 813 socket. Transformer terminals are theaded with nuts.

To save the $5 cost of USAF-NAVY *Operating Instructions* a table lists A and B control settings for band edges and 50 kHz higher.

IMPROVING YOUR HR-2

Note: The author of this article is T. L. Greenman WA1KFZ who can be heard daily working CW through the 04/91 repeater on Mt. Greylock, Mass.

Regency HR-2 transceivers are great little rigs for the money: however, like all other ham rigs, there is always room for improvement.

If you are a proud Regency owner and live where split channel repeaters exist, you know co-channel selectivity can be a problem. The HR-2, .2A (03-04 serial prefixes) use a single ceramic filter in the 455 kHz i-f strip for all the selectivity. The easiest way to improve the selectivity then is to change this filter for a more selective unit. The sharper filter which cures the problem without causing other problems is a Murata Model CFR 455D which may be obtained from Murata Corp. of America, 2 Westchester Plaza, Elmsford, New York 10523. Prices are $14.30 each or $11.30 for 3 or more.

The new filter pin locations are shown in Fig. 1. The new filter is longer and narrower than the original filter and its installation requires the drilling of 4 new holes in the P.C. board for its installation. In case Murata changes the case tab location with respect to the ground leads, check the two ground pins with an ohmmeter for continuity.

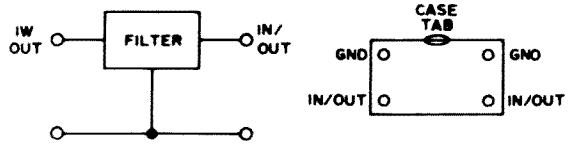

Fig. 1. Schematic diagram.

To install the new filter:

1. Remove the old filter using a small (37W) soldering iron, taking care not to heat the board or pin excessively. The easiest method is to remove the solder from each pin, and then push the filter out.
2. Next, using the new filter pins as a locator and Fig. 2 as a guide, drill four new holes (3 for leads and 1 for case tab). Index the new filter on the lower left pin hole as in Fig. 2.
3. Place the filter into the holes and carefully solder the five places.
4. Inspect the board carefully for solder shorts, etc.
5. Put the unit back into its case and turn on the receiver.
6. Find a channel with a weak signal on it and, using a diddle stick, adjust the quad coil (the i-f looking can next to the relay contacts) for clearest audio.

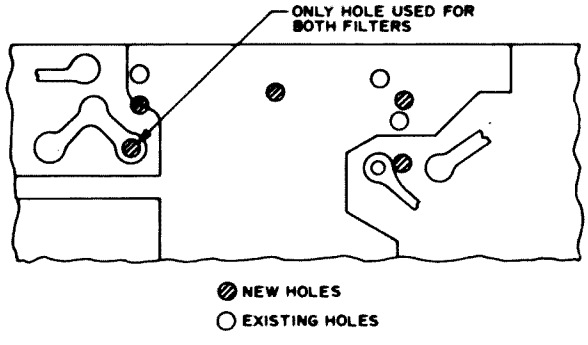

Fig. 2. Bottom view of receive board. Front panel on right.

Your selective receiver is now ready to go. You may notice a slight change in the squelch control action, and a slight improvement in receiver sensitivity.

12 Channels with the Regency HR-2

Gleaned from The Squelch Tale *publication of the Northern Berkshire Amateur Radio Club (WA1KFZ repeater), and submitted by WA1KJI.*

Six channels may be adequate in most parts of the country, but on those areas where repeaters are springing up every few weeks, a few extra crystal channels could help.

Fortunately the Regency HR-2 comes with a twelve position channel switch, so all you have to do to expand its coverage is add six more sets of crystals for the transmitter and receiver. There is room in the HR-2 for these, particularly if you are using an external speaker.

The process is simple. The six channels built into the HR-2 run down to the crystal sockets as you can see on page 12 of the instruction manual. All you have to do is add six more crystal sockets on a piece of Vector board 2¼ x 1 with .062" holes on .2" centers, plus six trimmers and six 36 pF capacitors per Fig. 1. Run short wires from the crystals to the switch and ground the other end of the circuit someplace handy. You can work out the mechanical problems or just tape things together, as you wish.

MORSE CENTENNIAL

Next April 2 will mark the 100th anniversary of the death of Samuel F. B. Morse. It is hard today to realize how great a debt the world owes to this painter-inventor and the magnitude of his contribution not only to American life but to communications all over the civilized world. His experiments proved that using a predetermined code, human intelligence could be transmitted long distances over a wire, with the speed of light.

He was born in Cambridge, Mass., 1791, and died 81 years later in 1872 in New York City. As a student at Yale (with a flair for sketching) he attended lectures on the new marvel, electricity. He and his brother Sidney invented a pump which was used on fire engines.

But he needed a means of livelihood and for 22 years he painted portraits in the United States and Europe, where most American artists studied in those days.

In 1832 he learned that a magnet was created if an insulated wire was wound around an iron core, and an electric current was sent through the wire from a Leyden jar. He felt that this property could be used to transmit human intelligence. He made numerous sketches of such a system, and this led to his devising a crude sending apparatus and a code with which to identify the message.

From 1832 to 1837 he worked on his invention at New York University where he was a teacher of the art of design and eked out a poor existence by painting portraits, too.

In 1843 Congress voted $30,000 for the construction of his experimental telegraph line between Washington and Baltimore, and on May 24, 1844, Morse sent over the line, in the presence of many high officials, the famous message "What Hath God Wrought!"

There were other efforts to devise practical telegraphs all over Europe, but all of them were visual systems, leaving no record of the messages. Morse's machine, on the other hand, left a record on tape and was the first practical recording telegraph.

Within a few years the whole Eastern United States was covered by short telegraph lines. Finally, in Rochester, N.Y., a movement began in mid-century to merge a number of them and within a dozen years more than fifty of the various lines had been combined into the Western Union Telegraph Co., which eventually covered the whole country. By 1862 a wire reached California, just seven years before the first transcontinental train got there.

Museums, colleges, railroad organizations, art galleries, professional and amateur telegraph associations, radio, television and historical bodies all will mark the centenary of the death of Samuel Finley Breese Morse, the man who annihilated space, on April 2, 1972. He died in New York City and is buried in the beautiful, park-like Green-Wood Cemetery, Brooklyn, N.Y., under a 15-foot-tall monument, surrounded by the graves of 34 of his kin.

Amateurs interested in more information on the Morse Telegraph Club should write to Joseph B. Milgram, President of the New York Chapter, 952 East 19th Street, Brooklyn NY 11230, to whom we are indebted for this item.

UPDATING AN OLD RECEIVER

You who fear to insert the tip of your soldering gun beneath the lid of your factory-made equipment, read no further. This article will blow your minds, for the project it describes involves removing the crystal filter, diode detector, noise limiter, and part of the avc circuitry from an "outdated" diode detector AM/CW receiver. The parts and circuits removed are then replaced with circuits and systems designed for the best reception of SSB, including just about the smoothest audio-derived agc system to be found anywhere. My conversion project was a 75A2, but the principles and circuits can be used in converting any receiver.

I am presently in the throes of relearning the code. I unwittingly let my W8RHR license lapse through simple inertia, and now must pay the price. (Why don't they make CW men pass an elocution test?) When I'm not copying practice code, I spend my time building and rebuilding, hoping to be ready next spring with a rig which will do justice to the excellent conditions which will prevail on the DX bands when I make my re-entry into the world of amateur radio. Naturally, I'll be

SSB. The first project on the agenda, therefore, was the conversion of the 75A2 I purchased from a local ham. Of course, a mechanical filter. And a crystal lattice for CW. And a good product detector and agc system with suitable noise limiting. This article is devoted to all of those who have failed to achieve the desired results when tackling a similar conversion.

Most such failures he in the area of the product detector and agc. The installation of the filters is no problem; just follow the Collins directions. A Collins F455FB21 and X455KQ200 were mounted with their individual peaking components and the selectivity switch in a minibox. This assembly replaced the crystal filter and its output coil, which were removed. The mixer output coil was also removed, and B+ to the mixer plate was fed in parallel to the filter input coils through a 10 mH *rf* choke (Fig. 1).

The product detector and agc system did not prove as simple. There were a number of criteria which I had to consider in designing this circuitry for the 75A2. It was essential to have a high degree of overload tolerance, a very efficient product detector, and lots of audio to rectify for the agc. These characteristics, always desirable, are an absolute necessity in the 75A2. In this receiver, *rf* gain control is accomplished by varying the grid bias of the *rf* and *if* stages, as opposed to the more usual cathode bias control. The variable bias is tapped into the avc line through a resistive network which shunts the line and loads it rather heavily. In order to derive maximum benefit from the agc system, it is desirable to run the *rf* gain control as nearly wide open as possible at all times. Thus, plenty of agc voltage is required to prevent detector overload, and a high degree of overload tolerance is required of the detector.

Other criteria were my desire to stay with tubes rather than go solid state in this particular application, since I have had some unfortunate experiences with transistor circuitry "taking off" in the proximity of heat-producing tubes. In addition, good product detector action is more difficult to obtain with transistors than with tubes, though some of the new FET circuitry seems to hold the answer. Simplicity (less to go wrong), minimum number of tubes (less drain on the 75A2 power supply), and stable operation completed the list of requirements.

A number of product detector circuits were built, tried, and rejected. The double

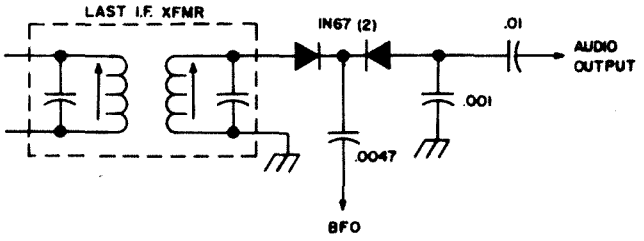

Fig. 2. A product detector having excellent characteristics can be simply installed in most receivers using two 1N67's in the above circuit. For use in the 75A2, however, this circuit did not provide sufficient output for adequate AGC action, even when amplified.

diode type (Fig. 2) using 1N67's back to back has excellent characteristics, but the output is too low to yield the kind of agc action required, even when amplified. Without exception, the triode circuits I tried fed through considerable 455 kHz bfo voltage, even when the output was filtered using tuned traps. Too much stray coupling between audio and *if* stages. The result was erratic agc action and bfo mixing in the *if* strip. Not good. In addition, triode and pentode circuits using cathode bfo injection were quite susceptible to overload. The low impedance presented by the cathode reduced bfo voltage enough to allow the *if* signal to over-ride the re-injected carrier.

Finally, the familiar 6BE6 circuit was chosen (Fig. 3). It out-performed the other circuits tried in practically every parameter. Output was at least as high as with any other circuit...higher than most. It offered by far the best overload characteristics, and remained linear and undistorted through an extremely wide dynamic range, resulting in natural-sounding, undistorted audio. It was duly incorporated into the 75A2. The .0039 μF ceramic by-passing the plate to ground reduces response above 3000 Hz and kills any 455 kHz energy at the output. The circuit is stable and uncritical. The only precaution which should be observed is to keep bfo energy out of the *if* strip. This point could be taken for granted, yet I know that many home-brew product detectors have failed to live up to expectations because the advantages of the circuit were cancelled by bfo mixing in the *if's*. Incidentally, don't neglect to realign the detector *if* transformer. Replacing the heavy load of the diode detector with the light load of the product detector makes quite a difference in the secondary tuning and Q.

With the product detector percolating nicely, I turned my efforts to the development of an equally satisfactory agc system. In my experiments with other product detectors, I had derived agc voltage by rectifying the output of either the detector itself, or its amplified signal, applying the resultant dc to the existing avc line through a 100K resistor. I tried both of these approaches with the 6BE6 and was not able to obtain sufficient voltage by rectifying its output direct, in spite of its high level. When I amplified the output and rectified it, the resulting dc potential was actually too high, but the voltage swing with modulation was still not great enough. Suddenly, the light dawned, and I

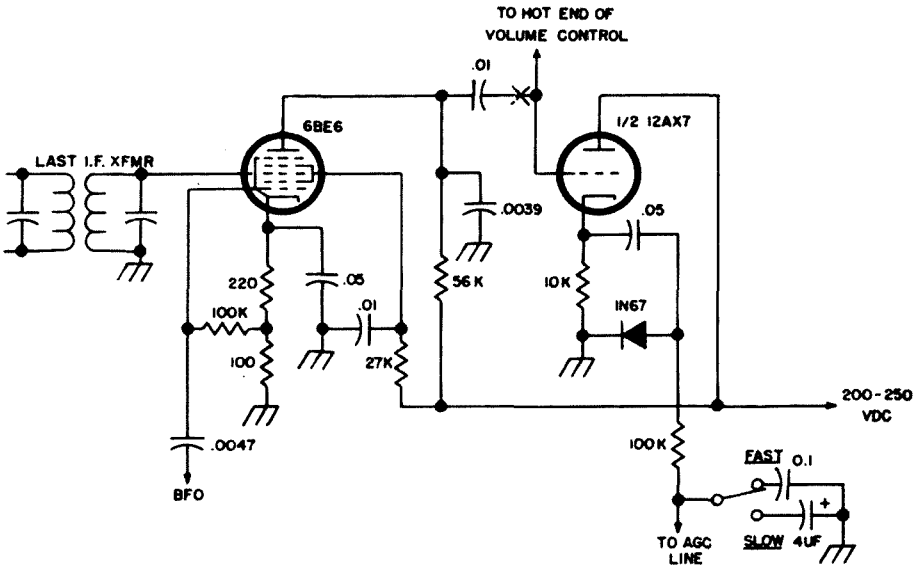

Fig. 3. Complete product detector and audio AGC system. Values of the capacitors switched by the "Fast-Slow" switch will vary from receiver to receiver. Cut and try is almost the only way to determine the value of the "Slow" capacitor. The "Fast" capacitor will ordinarily be the original capacitor shunting the AGC line in most receivers. Break at X to include the noise limiter circuit in Fig. 4.

realized that I had been overlooking the obvious impedance mismatch between ghe output of a tube and the low impedance of the diode rectifier. The cathode follower of Fig. 3 was quickly constructed and connected to the hot end of the volume control. A transformer hook-up was tried experimentally, but the cathode follower proved far superior in providing the desirable wide swing of agc voltage for a small variation in input to the detector. The unused 12AX7 triode was originally the avc amplifier in the Collins circuitry. I definitely recommend the cathode follower agc derivation as vastly superior to other methods commonly in use.

The 100K resistor was retained to avoid excessive loading of the agc rectifier. AGC action is so good that I only have to reduce the *rf* gain in the presence of strong local signals. The final touch is the variable time constant. In the CW position, only the original .1 μF capacitor shunts the agc line; switching to the SSB position adds a 4 μF miniature electrolytic, and increases the discharge time to about .6 seconds. The attack is only softened slightly...just enough to prevent the overshoot "click" at the beginning of a transmission or after a pause. Other receivers will require much smaller values of capacitance if their agc lines are less heavily loaded than that of the 75A2.

So far so good. Now for the noise limiter. Not so good. Every conceivable type of noise limiter circuit was tried. At first, I considered a noise blanker, but the cumbersome circuitry, space and power requirements discouraged this approach. I then turned to simpler possibilities. Using fast time constant agc voltage to an early *if* stage did not prove as satisfactory for me as it apparently has for at least one commercial manufacturer. Most series and shunt clippers using diodes created audio distortion to a degree which I found objectionable when they were adjusted for satisfactory limiting. In addition, they did not provide the advantage of limiting ahead of selective circuits, which is so desirable. *RF* and *if* clipping proved only marginally effective. I searched the manuals and magazines, but never found a circuit which surpassed the one shown in Fig. 4. It causes some audio distortion, but it is bearable, and limiting is sufficient under most conditions.

The diodes are biased by contact potential, and peaks exceeding it are shorted to ground through the appropriate diode. Silicon and germanium diodes were tried, but

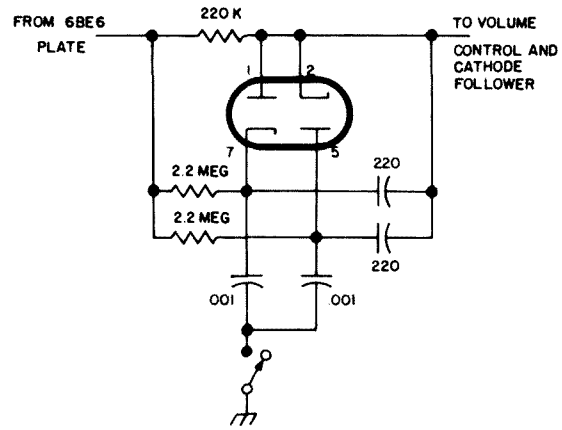

Fig. 4. The noise limiter. Audio distortion becomes objectionable on strong signals, so the limiter should be switched on only when needed. This circuit is at its best on weak signals, which can be copied even through heavy QRM. An i-f noise-blanker would be much better, but space and power considerations required a compromise. It's far from the ultimate, but it works better than most circuits and is at least as good as any other tried.

seemed to cause more distortion than the 6AL5 because of their greater sensitivity. This can be adjusted, but the 6AL5 was there, so I used it. The 220 pF capacitors suppress dc spikes, which are troublesome at high clippink levels and relieve some of the harmonic distortion generated by the clipping action. This clipper definitely cannot be left in the circuit at all times. It should be used only when needed, since strong signals will be clipped and distorted. It is especially useful when hunting through QRN and atmospheric rubbish for weak signals.

The addition of a 5:1 reduction drive and oversized tuning knob completed the first phase of my 75A2 conversion. It's almost overload proof. AM reception is possible, though definitely inferior to diode detection. The product detector–agc system is at least the equal of anything in current commercial usage, and a great deal better than some. All in all, I don't feel I could be better off with a brand new receiver. And that's the beauty of home brewing. I get something for less than it would have cost off the shelf, learned a few things in the process, and got a real feeling of satisfaction out of making it work.

What's next? A 6 meter conversion of the old 11 meter band, continued efforts to develop a satisfactory noise limiter, and a Q multiplier rejection filter built right into the 75A2, of course!

W8RHR

LEARNING FROM EMERGENCIES

Experience is the best teacher, obviously, so it is possible that much can be learned from the problems that arose during the February 1971 Los Angeles earthquake. The Los Angeles SCM has published an interesting and lengthy report on the effort, and I believe that the conclusions he reached will be of value to every club and individual concerned with providing emergency amateur radio communications.

Disaster Preparation

Operators for a particular Emergency Operating Center should be recruited from a diverse physical area. The W6IN Society had many regular members unable to assist as they were personally involved in attempts to provide solely for their immediate families. There is a need for the individual radio amateur to be well prepared as well as the emergency oriented groups in which he participates. He must have his own family cared for in order that he can even be available in time of disaster.

Radio amateurs should establish an emergency kit or list of required items to take on an emergency operation. This kit should contain sufficient items to provide food, clothes, spare parts, etc., which might be needed to render a man self-sustaining for 72 hours in the field.

The telephone tree (one individual calling a list of persons who in turn call an established list on the telephone) usually is excellent for exercises and drills, but it proved useless within this disaster area. There was no telephone service. An activation system involving persons reporting to a gathering frequency or a specific location is to be preferred.

Emergency power and equipment must be tested regularly at definite intervals and for substantial periods to insure its being in suitable operating condition. The Emergency Operating Center generator that failed had been tested weekly on Mondays for fifteen minutes, but had never been run for any substantial period of time. The fuel pump quit, it lacked sufficient radiator water (water mains were broken by the quake), and the fuel supply was low.

Should an Emergency Operating Center become unusable it is vital that some provision be made for a portable command post (preferably a mobile command post) with either permanent equipment installed or provisions made for equipment. A mobile command post should not be stored at the same point as the Emergency Operating Center or both may be lost at the same time.

Contacts established with local business firms, concerning the use of necessary equipment accessories and supplies in time of disaster or need, will prove extremely beneficial.

It must be remembered that amateurs are supporting local government disaster efforts as communicators and are not responsible for much of the planning, securing of goods and administrative decisions. Also a single unpleasant confrontation with a city official can change the image presented by the entire operation.

The role assumed in this effort unfortunately encompassed more than that of a communicator to the extent of becoming an administrator in a decision-making position. In retrospect this is undesirable and undermining to the general efforts of amateur radio to establish better working relations with public administrative agencies.

It is also noted that it is highly desirable to have available to the proper administrative decision-makers the ability to monitor other services (hospital, police, fire, etc.) at the Emergency Operating Center.

A professional appearance of the radio amateurs making contact with disaster officials is highly recommended. This would include proper dress and the presence of mature attitudes.

Overall communications coordination efforts with other amateur radio groups hoping to provide some service in the disaster area is vital. Groups of well-intending amateurs – unless recognized by the coordinating disaster group officials – can defeat the overall effort. Individual radio amateurs should be affiliated with a well-disciplined emergency group prior to a disaster if they expect to be fully productive during a disaster. Amateur radio groups operating in such a situation must have good communications horizontally among those in charge during the disaster situation.

A universally recognized insignia, picture ID card should be established for those with a purpose in a disaster area. Any such ID must also be made clear to proper authorities engaged in the disaster operations.

During the Disaster

To "be prepared" is insufficient. Established communications groups must volunteer their services to

affected areas. Without such volunteering W6IN, for example, would have been hard-pressed to provide adequate communications to the City of San Fernando on an emergency basis.

Shifts for communications personnel should be established as rapidly as feasible for continuity and efficiency.

A quartermaster of radio gear, accessories and other equipment to be used during operations is necessary to coordinate their issuance. Some personal radio equipment was "lost" through inadequate control.

Some panic information was disseminated to the public by the news media pointing up the necessity for strict control over any media releases. Speculation and rumors should be discouraged on amateur radio bands as well.

Comments and Conclusions on Health and Welfare Messages

When mail took a significant time to cross the country and long distance calls cost considerable sums, amateurs performed a real service by relaying messages that were mailed for final delivery. The attitude of many amateurs regarding mailing of traffic today can be summed up by one comment :

"When offering to send a message without a phone number to a person with either an unlisted number or a number listed under another last name, the originating station would be well advised to provide the originating party with a free post card rather than essentially offer one at the expense of stations in the delivery area."

Individuals make long, futile efforts to locate numbers. Some attempt to ditch the stuff on someone else, possibly a mile or two closer, although the addressee would be a local call for the first station if a phone number were available. Also it is difficult to get a letter into the postal system at a point where delivery will be prompt. (A card put into the mailbox after the last pickup of the day stands little hope of next-day delivery.) With the present air mail handling of first class mail, any radio message eventually mailed will probably reach its destination later than had it been mailed at the source.

Many of the instant service nets have resorted to not taking traffic listings without telephone numbers and liaison with them is sometimes necessary for the older, basic traffic nets. Especially in a disaster, the delivery stations are sufficiently overloaded with traffic to be justifiably annoyed at having to devote large efforts to researching telephone numbers. Inclusion of telephone numbers on messages cannot be overemphasized.

Additionally it is suggested that the National Traffic System, the three Area Staffs and the ARRL's Communications Manager should establish special provisions for handling large volumes of traffic in disaster situations that can be activated readily. There has been no indication of any special, organized efforts on a large scale within NTS to accommodate the large traffic volume occurring only days after a national exercise in emergency preparedness in the form of the ARRL's Simulated Emergency Test, "SET." Along the same lines more emphasis is needed on faster routing and delivery of traffic in NTS (traffic originating in NTS after the quake typically took three or four days to reach California NTS circuits). In addition to simplified routing techniques the use of simplified message forms (as used on the instant service nets) should be objectively investigated for use in disasters as well as increased use of modes other than CW.

Inquiries into Disaster Areas

Most reports on disaster operations conclude with the thought that inquiries should not be sent into disaster areas. The previous paragraphs are evidence that these efforts have not exactly been heeded. In a disaster where 65 people died out of a population of over 7 million, it could be seen that the answer to "Are you OK?" was "Yes." If there was any need for help, no doubt the affected parties would have requested help. However, the enhancement of the radio amateur's image was felt by the participants to have justified the effort.

Two types of inquiries somewhat amazed a few amateurs. One was an inquiry addressed to a person at an "unknown veterans' hospital in or near Los Angeles." In other words, the originators were so concerned about Uncle Charlie they were glad to take advantage of free services to inquire about his state, but not quite interested enough prior to the disaster to even know where he lived.

The other was a public service group that originated all their health and welfare traffic with the organization's signature rather than the originating party. Delivering amateurs felt somewhat embarrassed at receiving comments like "What is this all about?" when delivering "Are you OK? From the XYZ County, East Coast State Emergency Helpers Organization" message to a person living fifty miles from the quake center.

Overall Conclusions and Comments

It is noted that all disaster communications were handled by voice. With the exception of the Southern California Net on CW and the Navy MARS RTTY circuit, the health and welfare message load was handled by voice. CW, albeit more efficient for exchange of message traffic between experienced operators is a skill that has not been developed by enough amateurs to result in an effective disaster service. Complaints were voiced by Southern California Net members about lack of coverage in many areas which resulted in many messages being delayed even more.

The ease of training operators, reorienting an operation (setting up separate frequencies for different areas, for instance) and making large numbers of people aware of what's happening and capable of helping, makes voice by far the more effective means of disaster communication.

The Future

While it was a learning situation for Los Angeles AREC, this disaster communications operation demonstrated the value and merit of AREC. Several steps are being taken to improve and develop AREC in the Los Angeles Section under the leadership of the Section Emergency Coordinator, WA6QZY. FM has been clearly demonstrated to be a highly effective form of mobile and emergency communication for which reason 146.82 MHz FM simplex has been designated as the section-wide AREC emergency and mobile frequency in the Los Angeles Section.

Through the cooperation of the Edgewood Amateur Radio Society, Inc., the W6FNO repeater will repeat 146.82 MHz to 146.70 MHz. Also the Palisades Amateur Radio Club of Culver City has made their repeater, WB6ZDI, available to Culver City AREC (146.61 MHz in, 147.33 MHz out FM). Hopefully other radio clubs will also provide such support of AREC. 14302 kHz has been designated as the section's health and welfare frequency. A command channel on 2 meter FM for ECs, SEC, SCM and their assistants is being developed as is a high frequency band frequency for use as a gathering point. Discussion is also being given to an information station which would be used on a regular basis as an Official Bulletin Station.

Solid State Tuneable IF

Fixed-Tuned, 1.65 MHz IF Companion Unit to 28–30 MHz IF in January, 1970 issue of 73

This is the detailed low-down on the construction of some practical i-f stages for amateurs, including windings, cup-cores, etc,. for 1.65 MHz, employing techniques you can use on other frequencies as well.

There are several 455 kHz i-f strips on the market which work quite well, however these are a compromise in the trade-off on low image versus selectivity. The easiest way for the home-brewer to be sure to obtain narrow-band selectivity at low cost and in battery-portable form is to use a low i-f frequency. This means image trouble unless more conversions are used. If this is done both freedom from image *and* selectivity result. And if you tap into the outputs of both i-f's you can have an instant choice of broad or narrow bandwidth on a switch. The business of crystal filters is left to the professionals, resulting in receivers in the hundreds of $.

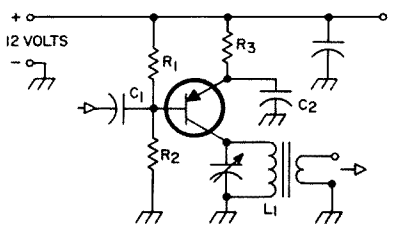

Fig. 1. Schematic of the fixed-tuned first stage.

DC Collector Voltage at the Ground Level

This is definitely good. Fig. 1 shows the simplicity of the first stage, which is fixed-tuned. What could be simpler? And it works very well. One coupling capacitor to the base, one bypass capacitor for the emitter, and that's it. All coils have one side grounded to the copper-clad baseboard.

Base Resistors

A number of tests were run on these items, which were found to be non-critical, as long as the ratio is held to furnish the needed base turn-on voltage. Values from 5K down to 250 ohms were tried for R1 (Fig. 1). At 250 ohms the shunt resistance across the base began to lower the gain. Naturally R2 has to be changed for every change in R1. A ratio of between four to one and six to one is good. I settled for 2.2K for R1 and 12.5 for R2, but this ratio may change a little for other transistors.

Input Tuning Not Required

This also was tested carefully. The output of the mixer from which the 1.65 MHz i-f was derived is already tuned, so it is really a question of how many tuned circuits you want to use. Various arrangements of tuned base coils were tried, with little increase in gain noted, so tuned circuits were left out of the input.

Interstage Coils

A number of different types of i-f transformers were wound and tested, with different iron cores, the matter of size entering here to a considerable extent because there will be a number of stages and also a hand-carried rig has to be kept as small as possible.

You can get real fancy here in the matter of i-f transformers, and wind them up with Litz wire, original German "Litzendraht," which is made up of many strands of small size enamel wire, example, "5/40." This is 5 strands of no. 40 enamel wire, and *below* about 7 MHz it does increase the Q to any remarkable extent. To match the benefits of this wire you can use fancy cup cores of powdered iron from Holland, and end up with a Q of 300 to 400 around 455 kHz. But, and it's a big but, you can't hold it!

The necessary air gap changes, and temperature, moisture, etc., put in their two cents worth also.

So, in one sense, it is better, at least more permanent and easier for the home-brewer to use more stages each with a lower Q and greater stability. For the narrow-band section we will work on this question a little. One more tuned circuit, with another stage allows all of them to run with conservatively longer life, practically no heating, no feedback, and is much better if you want a little more selectivity.

That problem has already been solved here by having the choice of two bandwidths.

Threaded Core IF's

Refer to Fig. 2 for these items. When you random wind by hand, which is pretty easy and works all right, wind on 25 turns first, then one pi of 50 and then the other, as shown in Fig. 2. These separate pi windings increase the Q quite a bit, helping with random winding which does not have the best of Q ordinarily.

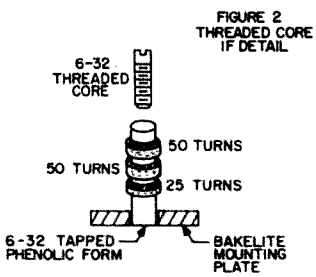

FIGURE 2
THREADED CORE IF DETAIL

Inserting the 6/32" iron core from the top keeps it in the main body of the winding for Q and coupling, and then reaching into the 25 turn part, serves to tune a little above and below the desired frequency for trimming, which is always needed.

As mentioned, you can make coils this way, or get real fancy. That's up to you. L2 is wound in the low place between the two fifty turn windings. L2 is generally a small number of turns, say from 2 to 5 turns. See final schematic and coil table.

What Not to Do

With three tuned circuits on 1.6 MHz, one in the 28 to 30 mhz mixer collector output, and one in each of the two i-f stages being detailed, it seemed only natural to try and achieve more Q with bigger and better powdered iron cores. Having a large selection of these, from some real small ones like 1/32" diameter O.D., up to the 1/2" loopstick sections, which same can be cut with a file, I wound up some 1.6 MHz coils with various turn numbers from 50 to 100. Well, the Q went up, but so did the troubles! The most nasty kind of feedback you ever saw crept in and then settled down to stay! And I couldn't neutralize it.

To cut it short, it was magnetic feedback, from the collector coil to the base winding on the previous collector coil, as I found out finally by removing the first stage and checking with just one transistor running. It oscillated all right, whenever the base coil was within several inches of the collector coil. Industrial designers (technicians) in large receiver companies can well laugh, someone else is paying for *their* days! Even though these windings were separated by more than three inches, trouble still occurred.

At last I remembered building a 16 to 18 kHz sideband filter some years ago (it worked good by the way) where I had to use tinned iron shield cans to keep down the magnetic coupling. It all came back to me then.

FOR THE PROFESSIONAL AMATEUR

SONAR (2 meters)
TRANSMITTER RECEIVERS (from 144 to 148 MHz)
COMPLETE FLEXIBILITY FOR
FOR MOBILE — BASE — HAND HELD

model FM3601 — 10 WATTS

- 8 Channels with Instant Push Button switching
- Solid State—using the finest quality silicon transistors
- Netting trimmer for each receive and transit crystal
- High quality mechanical filter for adjacent channel rejection
- Military-grade, glass-epoxy printed circuits
- Rugged, serviceable design - Compact, but not crowded
- Quick removal tray mount for security
- 25 transistors, 1 IC, 1 MosFet, 16 Diodes
- Receiver R.F. stage protected from overload
- Diode protected Dual-gate FET mixer
- Dual vari-cap phase modulator

Complete with microphone, mobile mounting tray and 2 pair of crystals (146.94T/146.94R and 146.34T/146.94R) **$299.95**
Model PS-2923 AC Regulation Power Supply $39.95

Model 2307 VHF-FM TRANSCEIVER
5 CHANNELS 1.6W MIN
HAND HELD PORTABLE

• Provides immediate voice contact with Base Stations, Mobile Units and other portable transceivers • Compatible with ALL 2-way communications systems • Snap-in Nicad Battery Pack cartridge • Receiver and transmitter can be operated on independent frequencies • Electronic mode switching/no relays • Receiver and transmitter sections are individual modules for easy servicing • Sensitive adjustable squelch

$450 complete with collapsible antenna and shoulder strap. Less crystals & battery cartridge*

Sonar Radio Corporation 73 Wortman Avenue, Brooklyn, N.Y. 11207

The Answer

The solution for compact units is to enclose the *outside* of the winding with powdered iron as well as having a center core. This causes the magnetic field to curve back in a sense, into the coil again, instead of travelling through the "near field" over to the base coil winding, where you most decidedly do not want it.

These kind of cores are known as cup cores, and there are millions available practically for free. Most of the i-f transformers made for *tube* i-f's have some beauties in them. Actually, two each. One is illustrated in Fig. 3A., with the winding I used, in Fig. 3B. I just happen to have (did I mention my 45 foot junk box?) a lot of these because of some ten years of work with sub-miniature battery tubes, like the 1V6, 1AD4, etc. So, you take the insides right out of one of these transformers, like a Miller no. 10C, and there are the two cup cores which are good for at least 455 khz up to several mhz.

Fig. 3. A. Cup core and B. winding for 1.65 mhz i-f.

They do a swell job on 1.65 mhz, with plenty of gain, no neutralization needed (so far) and, using 500 pf or more tuning, the variations in collector capacity with current on avc action can be eliminated.

The use of a large C also drops the impedance down for a better match with the transistor collectors.

A completely enclosed cup core in one i-f stage with a cover over the top, shown open in Fig. 3A, can be used very close to another stage without feedback, due to the greatly lessened external magnetic coupling. When you go in for real compact assemblies you will have to watch out for the electrical coupling (by capacity). Toroid coils are

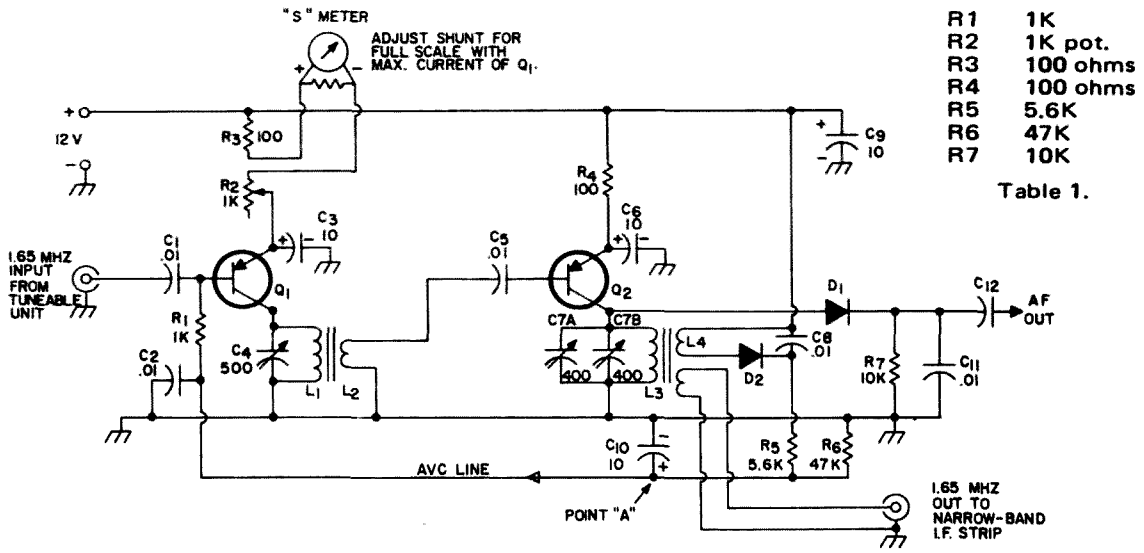

Fig. 5. Final schematic.

often used for this purpose but they run into money and are much harder to wind.

A Special, Simplified AVC

For some time now I have not been completely satisfied with the avc system found in most books for economical type circuits, which I have often used myself. This one is shown in Fig. 4.

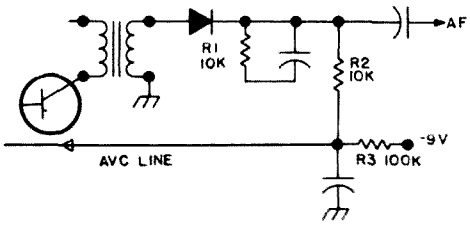

Fig. 4. "Old" avc circuit to be avoided.

R2 and R3 tend to load the diode with dc when you adjust them for best operation of the controlled stage, resulting in af distortion at certain levels of signal. As noted in Fig. 4., do *not* use the circuit shown there. Use the one shown in Fig. 5, the final and complete schematic, which has the new simplified circuit. It still does not use an additional transistor, but it does isolate the af from the avc action and produces beautiful af, by using two diodes.

D1 is a regular amplitude demodulator used solely for af. A secondary winding and D2 generate the dc voltage for the avc line.

In the absence of a signal, point A sits at about one volt negative from the plus 12 volt bus, resulting from the combination of D2, R1, and R2, and the negative bus which is also the ground plane in this i-f unit. This causes Q1 to operate at normal gain with a few milliamps of current.

An incoming i-f signal will build up a dc voltage through D1 making point A go through zero volts and, on a very strong signal up to around 2 volts positive with respect to the 12 volt bus. This of course automatically reduces the curent and gain of the avc controlled first i-f stage.

R1 and R2 can now be juggled for the best avc action with no effect at all on the af demodulation.

Completed Circuit

As mentioned, Fig. 5 shows the final schematic which operated in an excellent fashion with the 28 to 30 MHz tuneable section. The use of this tuneable i-f section allows the assembly of hand-carried battery portable rigs using crystal control all the way from the transmitter through to the local oscillators. The bandwidth of this fixed i-f on 1.65 MHz is about 50 to 100 kHz, depending on signal strength, and makes an excellent unit for search, tune-up, and medium distance reception with various front ends, antennas, converters, etc., on 432, 1296, and 2400 MHz. This amount of bandwidth allows your converter local oscillator crystal as well as the transmitter crystal of the lad on the other end of the QSO to "move" a little (they will!).

CHECKING ZENER DIODES

Over the past several years the cost of producing ultrapure silicon and the resultant devices has decreased at an extremely rapid rate. This reduction has been reflected in the cost of all silicon semiconductors. Perhaps the area in which the change has been most noticeable is in bipolar transistors, but at the same time the same reductions have been made in zener diodes too. Almost monthly one magazine or another features an article on the subject of testing and grading the "10 for" or "100 for" type of transistor. The subject of putting surplus zener diodes to use has not been popular and perhaps for this reason the price of unmarked zeners is extremely low. One large mail order house currently lists an assortment of 20 for less than $2. What then is needed to test and categorize these diodes? Fortunately the procedure and the equipment are simple.

First of all we must supply a voltage in excess of the zener point of the diode under test. This may be a special power supply built for the purpose or voltage may be taken from a bench supply or stolen from other equipment. We must also limit the current through the diode to a safe value in order not to exceed the dissipation rating of the device.

The diagram shows the simple setup in use at this QTH. The fixed resistor serves a current limiting function only. The voltmeter, which may be any VOM, VTVM, or panel meter, measures the drop across the zener. The potentiometer acts as a voltage divider and allows the voltage applied to the diode to be varied above and below the regulating point. If you are fortunate enough to have a bench supply available, the internal variable feature may be used and the potentiometer eliminated.

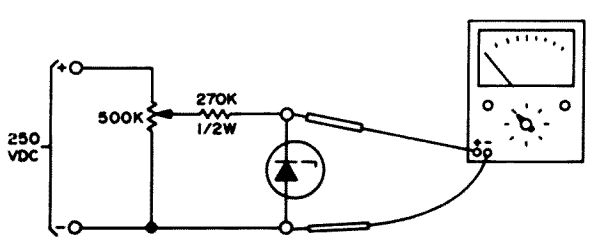

Fig. 1.

The constants given were chosen with an eye to minimum dissipation within the diode. The maximum current is limited to 1 mA, making this setup usable for a wide range of diodes types and sizes. Other constants may be selected if only higher power types are to be checked.

In use, the unknown diode is connected across the terminals with the indicated polarity. (Use trial and error if the diode is completely unmarked.) Always start with the potentiometer at the low voltage position and slowly increase the applied voltage until there is little or no increase in meter reading with increase in voltage. This is a rather abrupt indication. You will have no trouble detecting it. This is the voltage at which the diode will regulate. As they are checked, mark each diode with the correct voltage. A scrap of masking tape is a simple way of doing this.

A shorted diode will give no meter reading at any voltage – an open diode will allow the meter to read the supply voltage.

There remains one fly in the ointment. You will have to learn by experience the dissipation ratings of the various physical sizes of diodes. A short look at the actual size pictures in parts catalogs will be a good start.

GENERAL CLASS LICENSE STUDY GUIDE

Questions & Answers Part II

27. Define Ohm's Law. How does it relate to resistive and reactive impedance?

Ohm's Law states that the potential across an impedance, in volts, is equal to the product of current through the impedance, in amperes, and the impedance itself, in ohms. Stated algebraically, E = IR. Ohm's Law applies to any impedance, whether resistive, reactive, or a combination of the two. When dealing with ac, however, rms values for voltage and current must be used, and when dealing with a mixture of resistive and reactive impedance, appropriate complex-number arithmetic is necessary. (General course, Part I)

28. Describe ways of equalizing the reverse voltage drops across series connected silicon diodes.

To equalize reverse dc voltages across series-connected silicon diodes, moderately high valued resistors should be connected in parallel with each diode. 470,000 ohms is a typical value. This is enough smaller than the reverse resistance of the diode itself to equalize the voltage, yet large enough not to degrade the diode action. To equalize ac voltage spikes, low-value (.001 μF) capacitors should be connected in parallel with each diode. In many cases, both the resistors and capacitors are used. (General course, part VII)

29. What is the maximum legal dc power that can be delivered to the final amplifier of an amateur transmitter? How is this power determined?

The power applied to the final stage of an amateur transmitter cannot exceed 1000W (on some bands, 50W), as measured from the voltage and current at the dc input to the final stage. If power exceeds 900W, accurate means of measurement must be provided. (General course, part VIII)

30. Define instantaneous power, average power, sideband power, audio power, and peak envelope power. How is each related to the voltage and current that produced it? How is each related to the unmodulated carrier power?

Instantaneous power is the product of instantaneous voltage and instantaneous current, all taken at the same instance. It is a fictional concept; current exists only in relation to time, so that "instantaneous current" cannot be defined. Instantaneous power is, however, a useful concept, in that it is the highest power level likely to be encountered in a circuit.

Sideband power is the difference between average envelope power and unmodulated carrier power, and is not normally determined on the basis of voltage and current.

Audio power is the audio-frequency power produced by a modulator, and is the product of rms audio voltage and rms audio current. This is very close in value to sideband power, for a high-level-modulated AM transmitter, differing only by losses introduced in the modulated amplifier.

Peak envelope power is the product of

peak envelope voltage and peak envelope current, both measured at radio frequency.

Average power of a 100% modulated AM signal is 1.5 times the unmodulated carrier power. Sideband power is half the unmodulated carrier power, as is audio power required for 100% modulation. Peak envelope power is 4 times unmodulated carrier power. Instantaneous power may be any value between 0 and peak envelope power, depending upon the instant chosen. (General course, part III)

31. What is meant by the bandwidth of a signal? Compare the maximum necessary bandwidth occupied by a CW signal, an SSB signal, a double sideband signal, and an ordinary voice signal.

The bandwidth of a signal is the measure of the amount of rf spectrum space occuped by that signal, and is the difference (in hertz) between the highest frequency component of the signal and the lowest frequency component. Assuming a band-limited modulating signal in which no component is higher than 3 kHz for all voice signals, an SSB signal will require 3 kHz bandwidth, while both double sideband and ordinary AM voice require 6 kHz. Bandwidth required by a CW signal depends upon the transmission speed in wpm. Very slow transmissions (1 wpm or so) may use as little as 1 Hz bandwidth. Normal CW requires approximately 50 Hz. High-speed CW may require as much as 250 Hz. (General course, part IX)

32. What is neutralization and how does it contribute to proper amplifier operation? What procedure should be followed to properly neutralize an rf amplifier?

Neutralization is the process of canceling out all undesired feedback from an amplifier, and contributes to proper operation by preventing regeneration and self-oscillation of the amplifier. One method of properly neutralizing an amplifier is to disconnect all plate and screen voltages, leaving grid bias and heater voltages in place, and then applying normal input signal to the circuit while monitoring the output circuit with a sensitive rf indicator. The neutralization adjustments are then moved through their range until no feed-through of energy can be detected. This is the point of correct neutralization. (General course, part VIII)

33. What are the distinguishing features between series-tuned and parallel-tuned resonant circuits? How is the resonant frequency determined? Define the "Q" of a resonant circuit.

In a series-resonant circuit, the opposite-value reactances are in series with each other, making total circuit impedance equal to only the resistive component of the tuning components. Impedance is thus low at resonance, and current is high. In a parallel-resonant circuit, the opposite-value reactances are in parallel with each other, and the current circulates within this parallel circuit, making external current low and impedance high at resonance. The resonant frequency is that at which the reactances are equal, for series tuned and high-Q parallel tuned circuits. For low-Q parallel tuned circuits, several different frequencies of "resonance" are defined and the choice depends upon the particular application. The "Q" of the circuit is the ratio of energy stored to energy released per cycle, or roughly, the ratio of reactance to resistance. (General course, part IIB)

34. How does an ac power supply produce a dc voltage? Distinguish between a choke-input and a capacitor-input filter and compare their operating characteristics. What is dynamic regulation and how can it be improved? How do the output voltages of a full-wave center-tapped and a full-wave bridge rectifier compare?

An ac power supply produces dc output by means of rectification, a valving action in diodes which permits current to flow more readily in one direction than in the other.

A choke-input filter contains inductance as its first reactive component, while a capacitor-input filter has as its first reactance capacitance. The choke-input filter provides better voltage regulation with variations in load than does the capacitor-input filter, but produces less output voltage under light load conditions. The capacitor-input filter produces higher output voltage, but puts more strain on the recti-

fiers and transformer of the power supply.

Dynamic regulation refers to changes in power supply output level caused by changes in load current. It can be improved by providing additional energy storage (bigger capacitors) in the power supply's output circuit, or by reducing the power supply source impedance by any other means such as electronic regulation.

For the same transformer, the full-wave bridge rectifier produces twice the dc output voltage of the full-wave center-tapped rectifier circuit, because the end-to-end voltage capacity rather than the end-to-centertap capability of the transformer is used. Not all transformers will withstand the high voltage which appears at the centertap under the bridge connection, however. (General course, part VII)

35. How do resistors combine in parallel and in series to give total resistance? Capacitors? Inductors?

Resistors in series produce a total resistance equal to the sum of the individual values of each resistor in the chain. Inductors add inductance in similar fashion, if mutual coupling is excluded. Capacitors in parallel also accumulate value to the sum of the individual values.

Resistors in parallel, capacitors in series, and inductors (without mutual coupling) in parallel divide the current in such a manner as to produce a total value smaller than any individual value. The total is the reciprocal of the sum of the reciprocals of the individual values. (General course, part I)

36. How does voltage division occur across series-connected resistors? Capacitors? Inductors?

Across series-connected resistors, an applied voltage will divide proportionately to the values of the resistors, with the highest-value resistor developing the greatest voltage across it. The same is true of capacitors and of inductors, so long as the applied voltage is ac. The division in this case is proportional to the reactance of each component rather than the resistance. (General course, part I)

37. What does it mean to connect circuit elements in series? In parallel?

When circuit elements are connected in series, the same current flows through every element in the circuit. When elements are connected in parallel, current flowing through one element does not flow through any other element, but the same voltage appears across every element in the circuit. (General course, part I)

38. What is inductive reactance? Capacitive reactance? How is their value determined? How do like reactances combine in series? In parallel?

Inductive reactance is a measure of the degree by which the voltage in a circuit is retarded in phase with respect to the current. Capacitive reactance is a measure of the degree by which current is retarded relative to voltage. Inductive reactance is calculated from the formula $X_L = 2 \pi f L$, and capactive reactance from the formula $X_C = 1/(2 \pi f C)$. Like reactances combine in series and in parallel just as do resistances. (General course, part II)

39. Describe the transmission characteristics of the amateur bands below 30 Mc/s (MHz). List several propagation factors that influence signal transmission and reception in these bands.

Noise, both natural and manmade, and ionospheric conditions, which depend upon many factors, both strongly influence transmission and reception in all bands below 30 MHz.

1.8 MHz: Only groundwave useful during day. Range at night limited to only a few thousand miles, and that only when band is at its best. Noise usually high both day and night.

3.5 MHz: Noise high both day and night, especially in summer. Ground wave and very short range skip (200 miles or so) useful during day. At night may reach worldwide range but usually limited to one hemisphere.

7.0 MHz: Noise not so severe as on lower bands. Similar to 3.5 MHz during day but with somewhat greater range. At night, worldwide coverage possible and good coverage of hemisphere usual.

14 MHz: Very little noise except during

solar storms. Long range both day and night. Coast-to-coast skip during day, worldwide at night as usual matter.

21 MHz: Like 14 MHz, but band not usually open during sunspot minima. At its best, worldwide coverage during daylight.

28 MHz: Worldwide coverage for 2 years out of 12, useful primarily for local work rest of time. MUF usually too low for this band, but worldwide daytime DX possible when conditions are at their best.

(General course, part XII)

40. List the basic stages of a conventional superheterodyne receiver and tell what function each stage performs.

The rf amplifier stage isolates the mixer stage from the antenna, reducing unwanted radiation. The mixer stage converts the incoming signal to the fixed intermediate frequency. The first (or local) oscillator provides a signal to the mixer which selects the desired incoming signal. The i-f amplifier stage amplifies the signal, and provides selectivity. The second detector converts the signal from intermediate frequency to audio frequency, using the output of the beat frequency oscillator if necessary (for CW and SSB reception). The audio stages then amplify the detected signal to the desired amplitude to drive headphones or a speaker. (General course, part X)

41. How is the approximate length of a half-wave dipole related to its resonant frequency? Compare the operating characteristics of a half-wave dipole and a grounded antenna.

The length of a half-wave dipole antenna is approximately equal to 468/(resonant frequency in MHz) feet.

The half-wave dipole is electrically balanced; the grounded antenna is not. Feed impedance of a half-wave dipole in free space is 73Ω; that of a grounded antenna is approximately 35Ω. The half-wave dipole has a directional pattern, with nulls off the ends of the wire; the grounded antenna is omnidirectional. The half-wave dipole produces high-angle radiation; the grounded antenna's radiation is concentrated at low vertical angles. In general, the half-wave dipole provides better short and moderate range coverage, while the grounded antenna provides greater range for DX. (General course, part XI)

42. What do high- and low-pass constant-k filter circuits using balanced and unbalanced π-and T-sections look like?

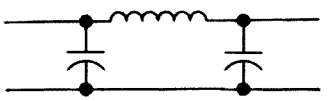

Fig. 1. Constant-K unbalanced π-section low-pass filter.

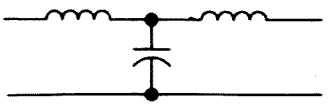

Fig. 2. Constant-K unbalanced T-section low-pass filter.

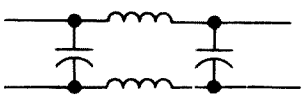

Fig. 3. Constant-K balanced π-section low-pass filter.

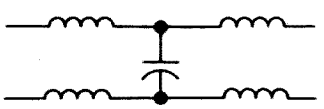

Fig. 4. Constant-K balanced T-section low-pass filter.

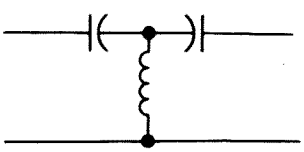

Fig. 5. Constant-K unbalanced T-section high-pass filter.

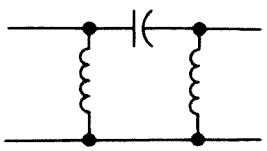

Fig. 6. Constant-K unbalanced π-section high-pass filter.

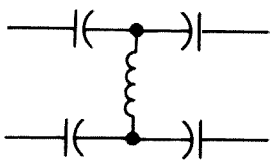

Fig. 7. Constant-K balanced T-section high-pass filter.

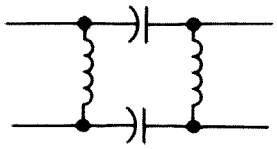

Fig. 8. Constant-K balanced π-section high-pass filter.

43. How can amateur equipment be protected from lightning discharge?

By means of a grounding switch. (General course, part XI)

44. What are the basic stages of a single sideband (SSB) receiver and transmitter and what purpose does each serve?

Basic stages of an SSB receiver are the first mixer, first oscillator, if strip, second mixer, second oscillator, and audio sections. The first mixer converts the incoming SSB signal to an SSB signal at intermediate frequency, by means of the output of the first oscillator. The i-f strip amplifies this signal, and provides the necessary selectivity. The second mixer (sometimes called a product detector) uses the output of the second oscillator to demodulate the SSB signal into audio, which is then amplified by the audio section.

Basic stages of an SSB transmitter are the SSB generator, the frequency determining circuits, and linear amplifiers. Within the SSB generator are included audio circuits and mixers, to generate an SSB signal at fixed frequency. This fixed frequency SSB signal is then mixed with a variable frequency signal to produce the final output signal, which is then amplified by linear amplifiers.

The transmitter and receiver are almost exact inverses of each other, which has led to the development of transceivers which share common stages between transmitter and receiver functions. (General course, part X)

45. List the three main classes of amplifier operation and explain the use for which each class is best suited.

The three main classes are A, B, and C. Class A amplifiers are best suited when low distortion is required, as for receivers and hi-fi amplifiers. Class B amplifiers provide higher efficiency and are best suited for use in portable and mobile equipment where long battery life is essential. Class C amplifiers are best suited for high-power rf amplifier application where their distortion can be tolerated. (General course, part VI)

46. What are "images" in a receiver?

Images are spurious responses in a superheterodyne receiver caused by the presence of an unwanted signal on the "wrong side" of the local-oscillator signal. If the receiver is designed to make use of the "input-minus-local-oscillator" difference frequency as its i-f, the "local-oscillator-minus-input" difference frequency is an "image." (General course, part X)

47. What is meant by "flat-topping" of a single sideband signal and what are some possible causes of it?

Flat-topping is a form of distortion in which the output signal's peaks are flattened rather than being reproduced accurately. It may be caused by excessive level of input signal, or by incorrect bias or loading in the amplifier stage. (General course, part VI)

48. What does grid current flow in a class A amplifier indicate?

In most class A amplifiers, grid current flow indicates incorrect operating conditions. The usual cause is severe overdriving of the input. It may also be caused by a failure of grid bias voltage. (General course, part VI)

49. Briefly discuss how a multiband "trap" antenna operates.

A multiband trap antenna includes parallel-resonant tuned circuits at critically spaced points in an otherwise normal half-wave dipole. At the frequency at which the trap circuit is resonant, the tuned circuits act as insulators and disconnect the ends of the antenna, so that the inner portion of the antenna acts as a half-wave dipole at

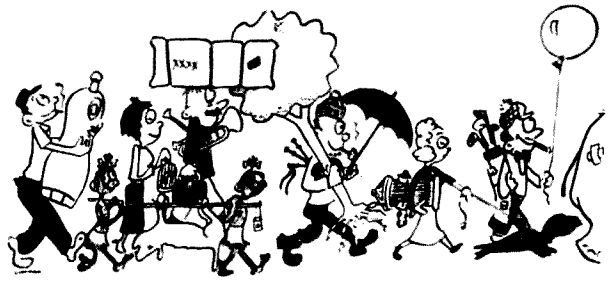
DEPT. 73, BOSTON MA 02101

this frequency. At lower frequencies, the net reactance of the trap circuits is inductive, and so the traps act as loading coils to electrically lengthen the wire. The full length of the wire (as electrically lengthened) then acts as a half-wave dipole at the lower frequency. By adding additional pairs of trap circuits, and by proper adjustment, the antenna can be made to cover all amateur HF bands. (General course, part XI)

50. How can the power input to the final amplifier of an SSB transmitter be determined?

The power input to the final stage of an SSB transmitter is determined by measuring plate voltage and plate current with dc meters having a time constant of at least ¼ second, and using the highest values indicated by the meters under normal modulation. (General course, part VIII)

51. Compare the operating features of the grounded grid and grounded cathode amplifiers.



Input of the grounded grid circuit is low impedance; that of the grounded cathode is moderate. Output impedance of the grounded grid is high; that of the grounded cathode is moderate. Current gain of the grounded grid is less than 1; that of the grounded cathode is moderate. The grounded cathode circuit reverses phase between input and output; the grounded grid does not. (General course, part V)

52. How is the bandwidth of an FM signal related to the bandwidth of the modulating audio signal?

The bandwidth of an FM signal is related to the bandwidth of the modulating audio signal in a complex manner which depends upon the modulation index. At low values of modulation index, when only the first pair of sidebands is significant, the FM signal's bandwidth (like that of an AM signal) is twice that of the modulating signal. As the modulation index increases, the bandwidth increases also. At a modulation index of 5 (used in commercial FM broadcasting), the bandwidth is 10 times that of the modulating signal. (General course, part IX)

This concludes the study list questions for the General class license. These questions also apply to the Technician and Conditional class license examinations, which embody the same technical content as the General class.

TECHNICAL AID GROUP

The Technical Aid Group is a group of hams who have indicated a willingness to share their knowledge and skills with others. They have volunteered to be of service to fellow hams and do so without compensation. If you have a technical question, look over the list to see who has competency in the area of your question. For many of the TAG members, descriptions of all areas of expertise would be lengthy, so an abbreviated description is given. When stating your problem, give as much information as possible and clearly state the difficulty. Enclose a SASE for reply.

For those hams who have a desire to share, the TAG is the thing for you. Send a brief note requesting the membership form, fill it in and send it back. It asks a few questions about your qualifications, and there is a check-list to indicate your fields of competence. These cover all modes currently used by hams, antenna design and theory, transmitter and receiver design for HF, VHF, and UHF, logic, ICs, general help, and other areas. As more members are added, their names and addresses will be published.

This list is not complete, but represents those former TAG members who have responded to a recent mailing and have expressed a desire to continue in the program. Comments from them indicate that they have enjoyed helping and all have been contacted frequently for advice.

Robert Perlman WB2VRW, 3 Josten Place, Hudson NY 12534. Electrical engineering student. Will help with Novice transmitters and receivers, and any help for beginning hams.

Thomas Laffin W1FJE, Box 133, Hillsboro NH 03244. Radio communications technician. Special aid to ex-CBers and those who need terms in easily understood terms; aid to Novices and Techs interested in MARS, RACES, CD, and CAP; how to build and scrounge parts; assistance on ham history, ATV, microwave, and general help.

Theodore Cohen W4UMF, 8603 Conover Pl., Alexandria VA 22308. Geophysicist. Specially prepared to answer questions about SSTV and ATV.

J. Bradley Flippin K6HPR, 116 Montecito Ave., Apt. M., Monterey CA 93940. Electronic engineer. Help with RTTY, data processing and programming, general.

Ira Kavaler WA2ZIR, P.O. Box 54, Flatbush Sta., Brooklyn NY 11226. Electrical engineer. Assistance offered in theoretical aspects of electricity and electronics from dc to UHF, design of equipment, computer programming, and signal circuit (failsafe) design.

Jon Teich WB2JAE, 22 Olden Rd., Edison NJ 08817. High school student. Novice and others, transmitter and receiver problems, logic, and general.

David Felt WB6ALF, P.O. Box 261, Sierra Madre CA 91024. Electronics engineer. Qualified help in logic, digital and analog design, solid state, AM and TV.

Robert Groh WA2CKY, 65 Roxborough Rd., Rochester NY 14619. Communications engineer. Bob can lend a hand in HF and VHF transmitter and receiver design as well as solid-state logic and digital techniques.

Carl Miller WA6ZHT, 334 Paragon Ave., Stockton CA 95207. Computer technician. Carl's specialty area is solid-state QRP.

George Daughters WB6AIG, 1560 Klamath Dr., Sunnyvale CA 94087. Research associate. HF transmitter and receiver, SSB, and solid state, are George's fields.

D. Hausman VE3BUE, 267 Northcrest Pl., Waterloo, Ontario, Canada. Student. Novice transmitter and receiver problems as well as logic, digital techniques and ICs.

Hugh Wells W6WTU, 1411 18th St., Manhattan Beach CA 90226. Electronics instructor. Hugh can help with AM, Novice problems, VHF-UHF receivers and converters, solid state, test equipment, FM and repeaters, and general help.

Charles Hill WA7LQO, 4005 Campbell St., Baker OR 97814. Student. TV, Novice transmitter problems, and logic.

John Perhay WAØDGW, Route 4, Owatonna MN 55060. EE technician. John will help with RTTY, AM, SSB, Novice gear, HF transmitters and receivers, solid state, ICs, and test equipment.

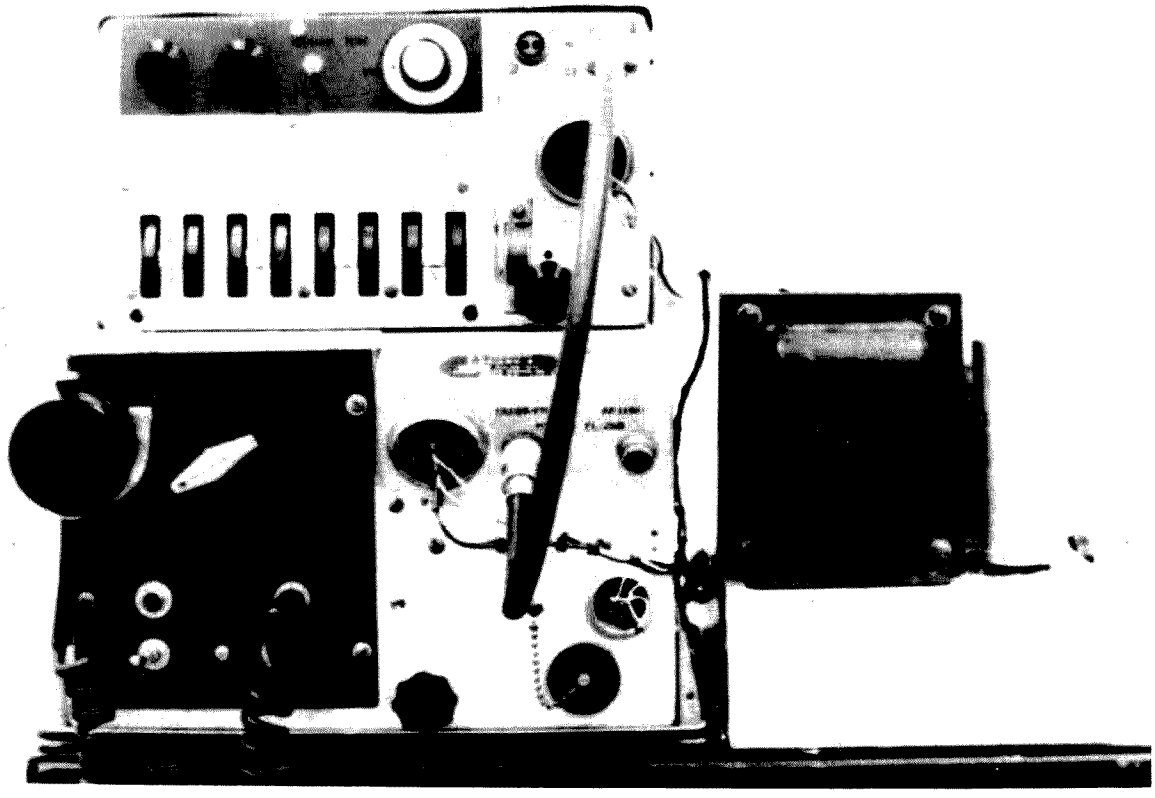
Jim Jindrick WA9QYC, 801 Florence Ave., Racine WI 53402. Consulting engineer. General help as well as HF, VHF, and UHF antennas, transmitters, and receivers.

William Welsh W6DDB, 2814 Empire Ave., Burbank CA 91504. Electronic engineer. Beginner's problems, code instruction, theory and regulations.

Ken Knecht K8VNT, Box 39, Clintondale NY 12515. Television engineer. TV, logic, and digital techniques.

Tom O'Hara W6ORG, 10253 E. Nadine St., Temple City CA 91780. Communications engineer. RTTY, TV, AM, SSB, VHF antennas, transmitters and receivers for HF through UHF, solid state, and general help.

Bruce Creighton WA5JVL, 2517 Metairie Ct., Metairie LA 70002. Electrical engineer. Antennas, Novice problems, solid state, logic, digital techniques, test equipment, and general help.



Tom Borok WB2PFY 215-33 23 Rd., Bayside NY 11360. Student. Tom is especially qualified to help Novices with their problems with transmitters and receivers, HF and VHF antennas, HF receivers, test equipment, and surplus, Morse code instruction.

Roger Taylor K9ALD, 2811 William St., Champaign IL 61820. Engineer. Roger is adept with AM, SSB, antennas, solid state, logic and digital techniques, ICs, test equipment, and other general help.

Orris Grefsheim WA6UYD, 1427 W. Park St., Lodi CA 95240. TV technician. Orris is capable of assisting in all fields of amateur work, DC through UHF, logic as well as Novice help.

John Allen K1FWF, 112 Edgemoor Lane, Ithaca NY 14850. Technical director. John's areas of assistance are VHF and UHF antennas, receivers, and transmitters, solid state and digital techniques, ICs, and SSB.

Putting The ARC-3 On Two

Neale C. Hightower WA4NAI/4
160 Fourth Street NW
Atlanta GA 30313

For the amateur who wants a step up from the lunchbox class of 2 meter equipment (no slurs intended) the AN/ARC-3 offers an excellent low-cost opportunity. A moderately stocked junkbox and a little scrounging can put the units on the air for an additional $10–15 cash outlay.

The ARC-3 system consists of five basic units: receiver, transmitter, control box, antenna, and dynamotor assembly. Only the transmitter and receiver are used in this conversion. Mating plugs are a matter of preference and cost. For fixed work a scheme is presented to avoid the need for these plugs. For a mobile installation, it is probably advisable to purchase these units if they are available. A good schematic is essential for this work, as is the case with most conversions. If one is not available from the supplier of the units, Bill Slep Co.[1] will supply separate schematics of the units. The price is $1 each.

Very few amateurs have the same needs or desires in equipment. Thus this conversion is presented as a number of "subconversions." Almost all are independent of each other. One can tailor the conversions

to suit his particular application by installing the features most useful to him.

Before starting the conversion, it is a good idea to have a rough idea of how the system works. Figure 1 shows a block diagram of the receiver system. The layout is conventional except for the automatic tuning mechanism and the harmonic generators. All frequencies (100–156 MHz) are tuned in 7 bands using 8.0 to 8.5 MHz crystals on their 11th to 18th harmonics. The harmonic generator chain is fairly narrowbanded; therefore, when it is detuned slightly from its center (the stages are not tuned to integral multiples of the crystal frequency), the output drops rapidly. Once a new channel is selected, relays change the appropriate crystal and a control tube senses that the harmonic chain is detuned. The tuning motor is started, turning the tuning mechanism. Normally, the tube would cause the motor to tune to the next harmonic and shut off when the chain output equaled the 14V reference. But if the previous channel was on the 12th harmonic and a frequency using the 17th harmonic was desired, the system would stop at the next harmonic (13th) instead. To prevent this the coding wheels

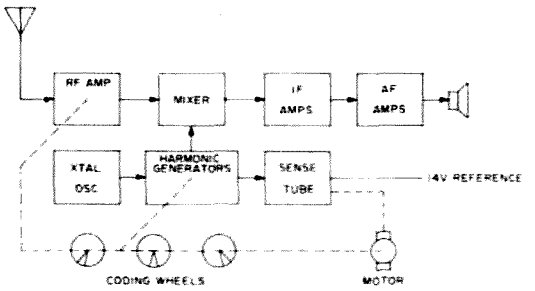


Fig. 1. Block diagram of receiver system.

are added. They select the proper harmonic and "kill" the harmonic chain output until the tuning mechanism is in the proper range. Then the output of the harmonic generators is applied to the sense tube for exact tuning.

The transmitter block diagram is shown in Fig. 2. Since it uses crystals from 5.5 to 8.6 MHz, all on the 18th harmonic, it is

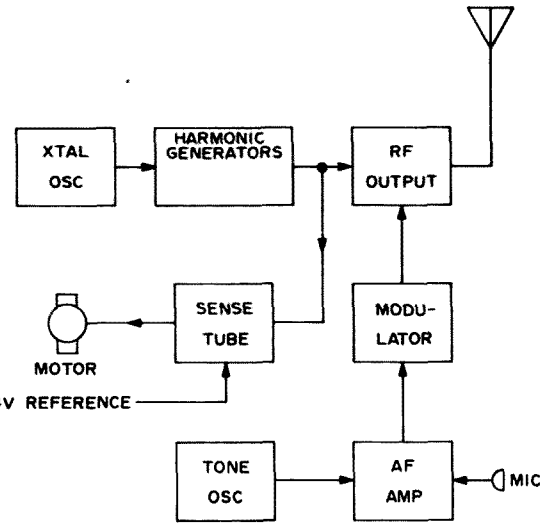

Fig. 2. Block diagram of transmitter.

only necessary to determine when the multiplier and output stages are in tune. The tuning mechanism is basically the same as that of the receiver except that the coding wheels are not employed.

Converting the Receiver

Unless it is to be used in some configuration very similar to the original, the following changes are recommended for the receiver:

1. Rewire the filament string for 12V
2. Provide an external B+ supply
3. Add an external audio gain control
4. Add external speaker (or headphones)

Two other features may be added:

5. Manual (continuous tuning)
6. Rf gain control

Filament String Conversion

The 24V filament lines may be converted for us on 12V (ac or dc) by the following procedure:

Identify R-201 (252Ω). It shunts the filament of V201; one side is connected in five leads, two on one post, three on another. The posts are jumpered together. Remove the jumper and all five wires. One wire goes back to V201. Reconnect it to the R201 post and add a jumper from this post to ground. Another wire goes to V205 through C206, the center feedthrough ca-

pacitor beside the tube. Identify this lead with an ohmmeter and attach it to the R201 post. Attach the other three wires to

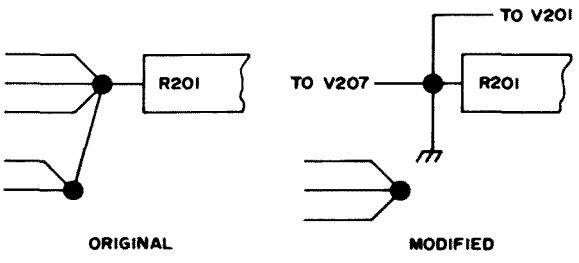

Fig. 3. Detail of 12V filament conversion.

the now empty "other" post. This change is described in Fig. 3. Identify the three posts on the rear of the brake, K202, which is located near the motor gearbox assembly. Two white wires are connected to the centerpost. One goes to pin 8 of V216. Connect this wire to some nearby groundpost. Replace the other wire Now run a new wire (20 AWG or larger) as indicated in Table I.

Table I. ARC-3 Wire Routing

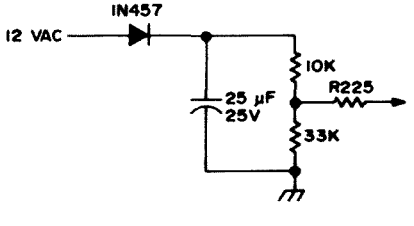
From	Pin	To	Pin
V216	7	V215	8
V215	8	R291	7
R291	7	V212	7
R291	7	V207	7*
V207	7	V203	3
V216	7	V209	4**

*If the filaments are to run on ac, disconnect R225 from pin 7.

** This is best done at a post near V209 to which R202 is connected.

Remove the lead from pin 2 of V207 and connect it to pin 7. Ground pin 2. If dc filaments are to be used, the conversion is now complete. The filament supply is now pin 12 of P202. Remove R291.

For ac operation (and utilization of the automatic tuning) a small dc supply must



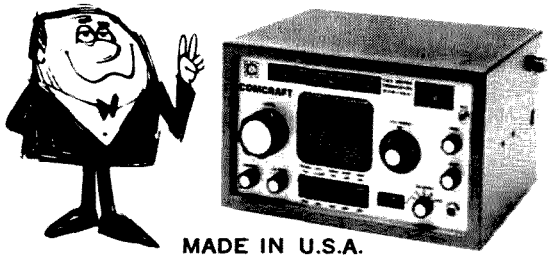


Fig. 4. Power supply for autotune operation.

2 Rigs in one!

THE COMCRAFT CTR-144

MADE IN U.S.A.

The First AM-FM Solid-State Transceiver For Two Meters

No longer is it necessary to choose between AM and FM on two meters. Now you can have both in one compact unit. Join the gang on the new FM repeaters yet still be able to "rag chew" with old friends either AM or FM anywhere in the two meter band.

COMPARE THESE FEATURES

TRANSMITTER:

- Built-in VFO (Frequency converted for stability)
- AM and FM both crystal and VFO
- Four transmit crystal positions (8 MHz)
- 12 watt input AM and FM
- High level transmitter modulation on AM
- Bandpass coupled transmitter requiring only final tune and load
- Three internal transmit crystal sockets with trimmers for netting
- One transmitter crystal socket on the front panel
- Deviation limiting
- 146.94 MHz crystal included

RECEIVER:

- Double conversion
- Crystal controlled first conversion
- MOS FET receiver front-end
- Integrated circuit limiter and discriminator for FM
- Envelope detector and series gate noise clipper for AM
- Built-in squelch for both AM and FM

GENERAL:

- Separate transmitter and receiver tuning
- Built-in 115VAC power supply
- Direct 12VDC operation for mobile or portable operation
- Optional portable rechargeable snap-on battery pack available
- "S" Meter also used for transmitter tune up
- Military style glass epoxy circuit boards
- Anodized lettering and front panel
- Baked epoxy finish on the cabinet
- 47 transistors, 22 diodes, 1 integrated circuit
- Dimensions: 10¼"W x 6¼"H x 7½"D

Warranty—90 Days Parts and Labor

The CTR-144 is available at your DEALER or order FACTORY DIRECT $459.95

COMCRAFT COMPANY
P.O. BOX 266—GOLETA, CALIF. 93017

Write for more information or use READER SERVICE

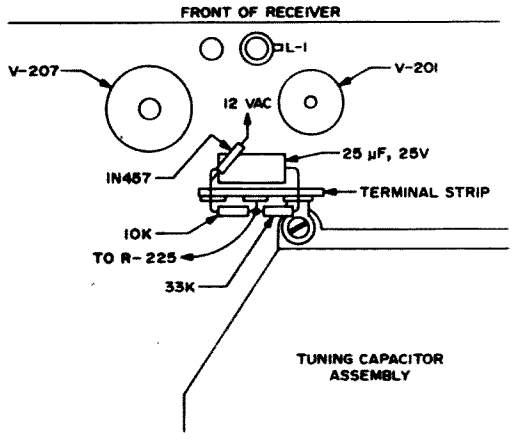

Fig. 5. Detail of autotune power supply mounting.

be added to produce the 14V reference. (If the filaments are ac powered and the autotune is unused, remove R225.) This reference voltage was originally derived from the center of the filament supply for V207 and V210. A peak rectifier and voltage divider may be added as shown in Fig. 4. The diode can be almost any type. The supply is mounted on a 3-terminal strip between V201 and V207 (Fig. 5). The ground lug is mounted under one of the bolts securing the tuner assembly to the chassis.

External B+ Supply

The supply shown in Fig. 6 is for both the transmitter and receiver. For those contemplating a mobile supply, the data in Table II should be helpful.

Table II. ARC-3 Voltage Requirements

Function	Power
Filament	12V, 7.5A
Receiver B+	225V, 100 mA
Transmitter B+	410V, 325 mA
Relays	28V, 500 mA

Table II. ARC-3 Voltage Requirements

To power the tuning motors, it is necessary to have a supply capable of delivering about 6A at 28V. Any less capacity will cause the autotune mechanism to malfunction. Thus automatic tuning for fixed (ac) work is not recommended.

The power transformer used was scrapped from an old (very old) television. It has a centertapped 12V winding to handle the necessary current. An exact replacement is not known, but only transformers from "monster" TVs will work. Instead, for most work it would probably be better to use two transformers. The inductors were removed from old TVs. As can be seen, the parts used are mostly junk, so feel free to substitute.

Connection to the receiver and transmitter was effected by removing the pin connectors from an octal socket. The older "wraparound" type were employed. If these are not available, most hobby shops carry small brass tubing which could be used.

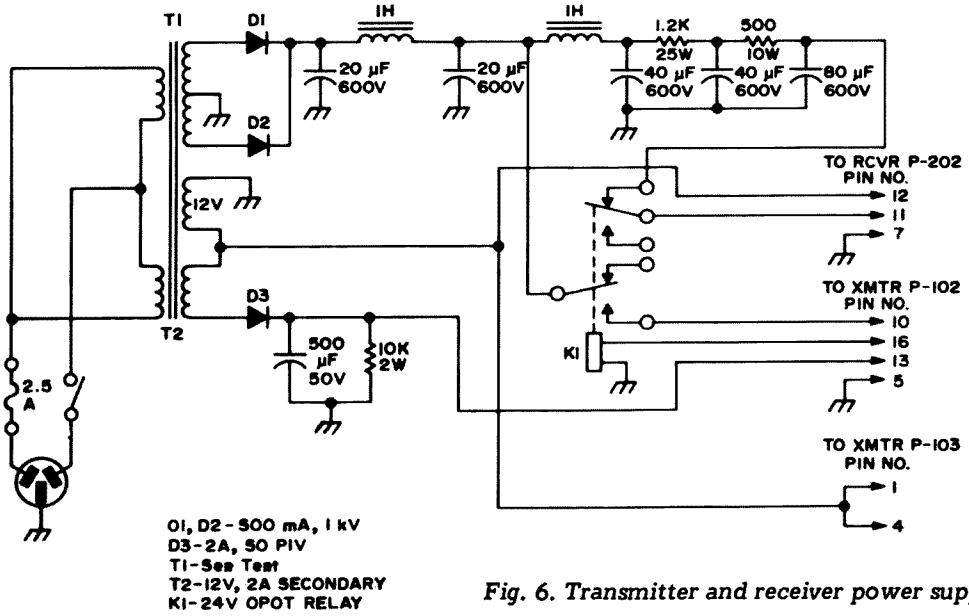

Fig. 6. Transmitter and receiver power supply.

The power supply used at WA4NAI was adapted from use on another project. A supply using a different layout would be more practical and esthetically pleasing.

Audio Gain Control

Disconnect C294 from pin 1 of V216. Remove R280, C296, R289, and R290 from the other side of C294. The last three components are mounted on the rear of the chassis on a point-to-point board. Remove R281 and R284. Add the audio gain control as shown in Fig. 7. One of the points cleared by the removal of C294 may be used as a tie point. If the leads are to be extended beyond the chassis, it would be wise to shield them. Moving one side of C294 significantly increases the gain of the stage.

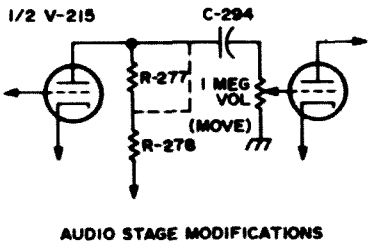

Fig. 7. Installation of audio gain control.

External Speaker

Two output impedances are available for a speaker at pins 16 and 17 of P202. Pin 16 is 50Ω and pin 17 is 600Ω. The 600Ω output could be used directly with headphones. A 600Ω line-to-voice-coil transformer may be installed to match a 4 or 8Ω speaker. One might also use a 45Ω speaker directly across the 50Ω output. Those wishing to replace the output transformer can use the Stancor A-3879. If the 12A6 tube is defective or missing, it can be replaced with the more common 12V6.

Tuning

The ARC-3 was originally designed for crystal-controlled reception on 8 different preset channels. If channelized operation is desired, all that is necessary is to supply 28V to the A+ terminal of P202 and 12V to pin 12. Attach a switch as shown in Fig. 8 and install crystals as determined by the following formula:

Where: F_C = xtal freq, MHz.

$F_C = (F_O - 12)/n$ F_O = operating freq, MHz.

n = harmonic ($8.0 \leqslant F_C \leqslant 8.5$)

Manual Tuning

Continuous tuning requires the conversion of the crystal oscillator to a tuned-grid-tuned-plate oscillator. In addition, one must arrange some method of keeping the rf and multiplier stages in tune. Several different schemes are possible, but the one presented seems the best for simplicity and versatility. The automatic tuning and relay logic are simply left unused by a combination of electrical and mechanical methods.

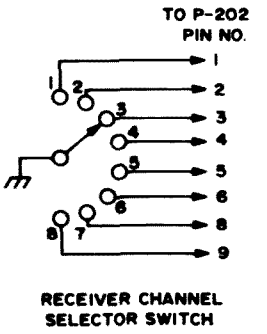

Fig. 8. Hookup for channelized reception.

Oscillator Conversion

Conversion of the oscillator involves replacing the crystal with an LC circuit tuned to roughly 8 MHz, adjustable over the desired range. Details of the circuit are shown in Fig. 9. To begin the conversion, remove the wire to pin 6 coming from the relay bank. L1 is mounted in the now vacant hole near V201. C1 is mounted on the front panel (over the old relay cavity). Connecting leads are threaded through the holes in the crystal sockets.

Alignment of the tunable oscillator can be done with reasonable accuracy on the air. Choose a signal near the bottom of the

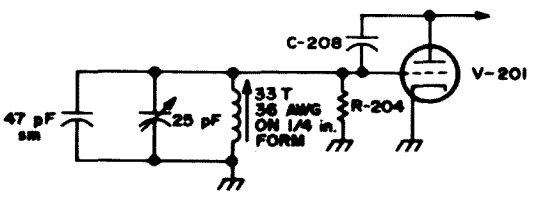

Fig. 9. Conversion of crystal oscillator to VFO.

band of known frequency and set the tuning capacitor to about 90% meshed. Now tune in the signal with the slug of L1 (it may be necessary to add or remove one or two turns). Three signals spotted across the band should give a reasonably accurate dial scale. Of course, a better job can be done with a signal generator.

In a mobile installation, it might be desirable to tune the oscillator remotely with a varactor. A suggested hookup is shown in Fig. 10.

Continuous Tuning

For fixed station use, a shaft and gear system are installed in the old squelch level access hole, and the control is moved to the rear of the chassis above the 12H6 detector. Begin by turning over the receiver and loosening the front, removing five screws on each side. Press the brake mechanism manually and turn the tuning shaft so that both setscrews designated in Fig. 11 can be reached with a splined wrench without again turning the shaft (this assures that alignment will not be lost between the tuning capacitors and the front dial). If the screws don't come out easily, heat them with a soldering iron and they will almost fall out. Carefully slide the front loose and remove the squelch control and bracket. Disconnect the control and mark the leads so that they can be extended to some other location. Drill out the brad which holds the slide assembly covering the squelch access hole. Mount an old potentiometer bushing in the access hole (ream it slightly). Figure 12 shows the mechanical details of the conversion. The gears used in this conversion are from the depths of a friend's junkbox. One could also use gears from an erector set (write the company or bargain with Junior), a slot car supply center, or belt and pulleys from an

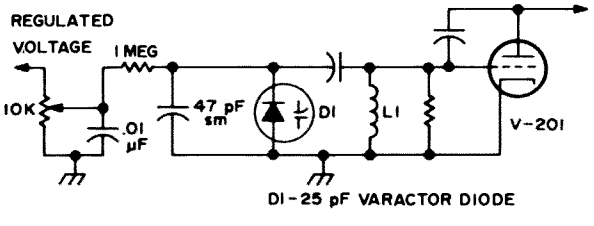

Fig. 10. Remote oscillator tuning circuit using a varactor.

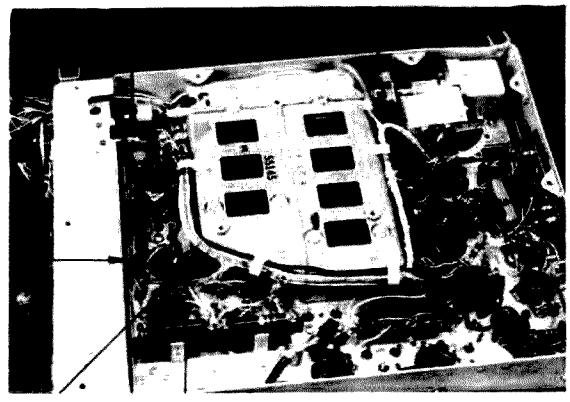

Fig. 11. Photo of manual tuning conversion.

old phono motor (use your imagination). Certain surplus equipment such as old bombing navigation devices is often a good source of small gears. Finally remove or loosen the setscrews shown in Fig. 11.

Tuning the receiver is like tuning a communications receiver having a preselector. Choose the approximate frequency of operation with the rf stages then tune the signal with the oscillator. Finally peak the RF stages.

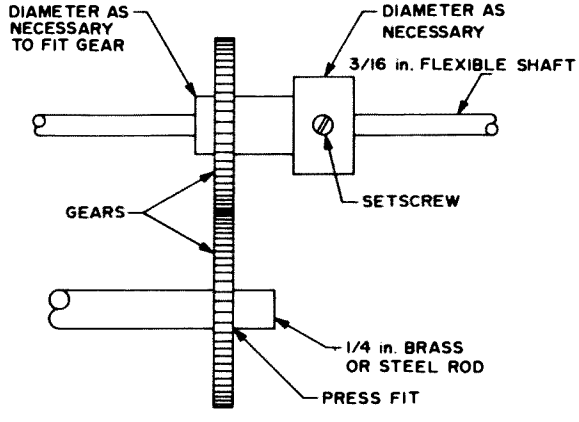

Fig. 12. Mechanical details of manual tuning conversion.

Rf Gain Control

An rf gain control may be added without too much trouble. The hookup is shown in Fig. 13. The pot is a half-watt unit, and any value near 25 kΩ will do.

Begin by removing the cover plate over the section of the tuner assembly which mounts V208 and V209. Carefully lift the ground end of R236 and add a one-lug terminal strip directly outside the side plate. Extend the ground end of R236 to

the lug. One can now run a wire from this lug to the front panel.

Transmitter Conversion

The transmitter involves somewhat less conversion than the receiver, since the output is left crystal-controlled. The bulk of the labor involves attaching a front panel and extending control leads to it. Additionally, a manual peaking feature for the rf stages is presented to avoid use of the automatic tuning motor and its accompanying 28V high-current supply. Provisions are made for a relative output indicator and a 12V filament supply.

12V Filament Supply

The transmitter filaments draw about 4.5A at 12V. In many cases, a transformer capable of handling this load is expensive.

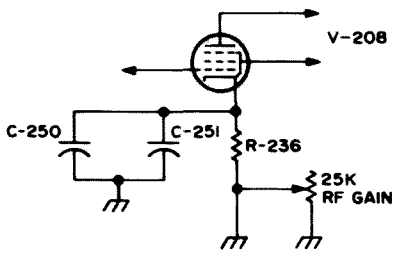

Fig. 13. Addition of rf gain control.

But a TV power transformer could be used by placing the 6 and 5V windings in series. The 5V winding is usually good only for a little over 3A. By bringing out a separate lead for the 6L6 modulator filaments, however, the filament drain can be split into 3.5 and 1A sources, as shown in Fig. 14. If such an arrangement is not necessary, the two separate lines can be paralleled.

Identify R132. Three leads are connected to one side. One goes to pin 7, V108. Remove and ground it. Remove the other two leads, solder and tape them together. Identify R131. Place a jumper across it or remove it and tape the leads together. Identify and remove R133 and the lead going from it to pin 7, V105. Remove R129 and R130, taping up the remaining leads.

Identify pin 7, V103. Remove both wires and solder and tape them together. Ground pin 7. Remove the lead from pin 7

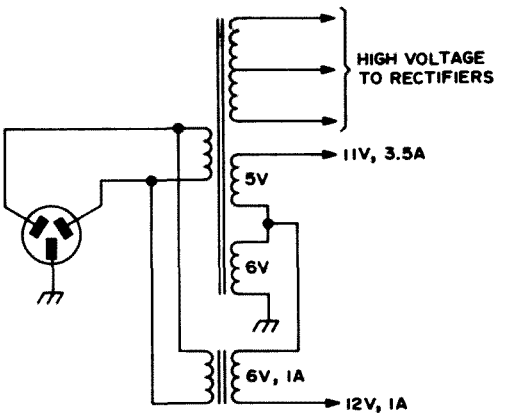

Fig. 14. 12V filament power supply.

of V102. Run a 20-gage or large wire via the following chart:

FROM	PIN	TO	PIN
V104	1	V105	7
V105	7	V102	2
V102	2	R132	tap
V105	7	P103	1
V107	2	P103	4

The 12V (ac or dc) can now be fed into pins 2 and 4 of P103 with 3.5 and 1A sources.

Front Panel Controls

Remove the crystal compartment door and fit a new piece of aluminum for the front panel. This is best done by using four sheet-metal screws. Removal of the relay contact covers should provide sufficient clearance for jacks, switches, etc. Details of

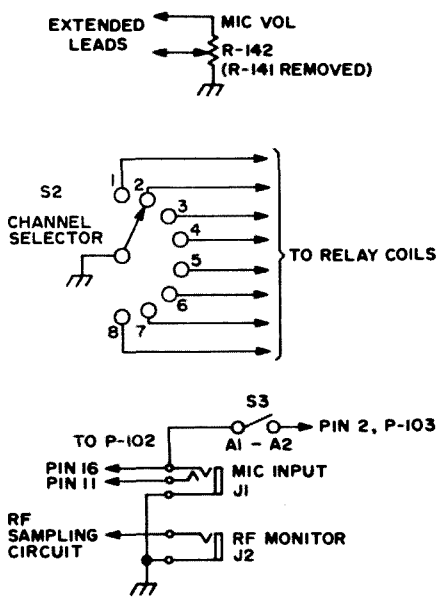

Fig. 15. Wiring of front panel controls.

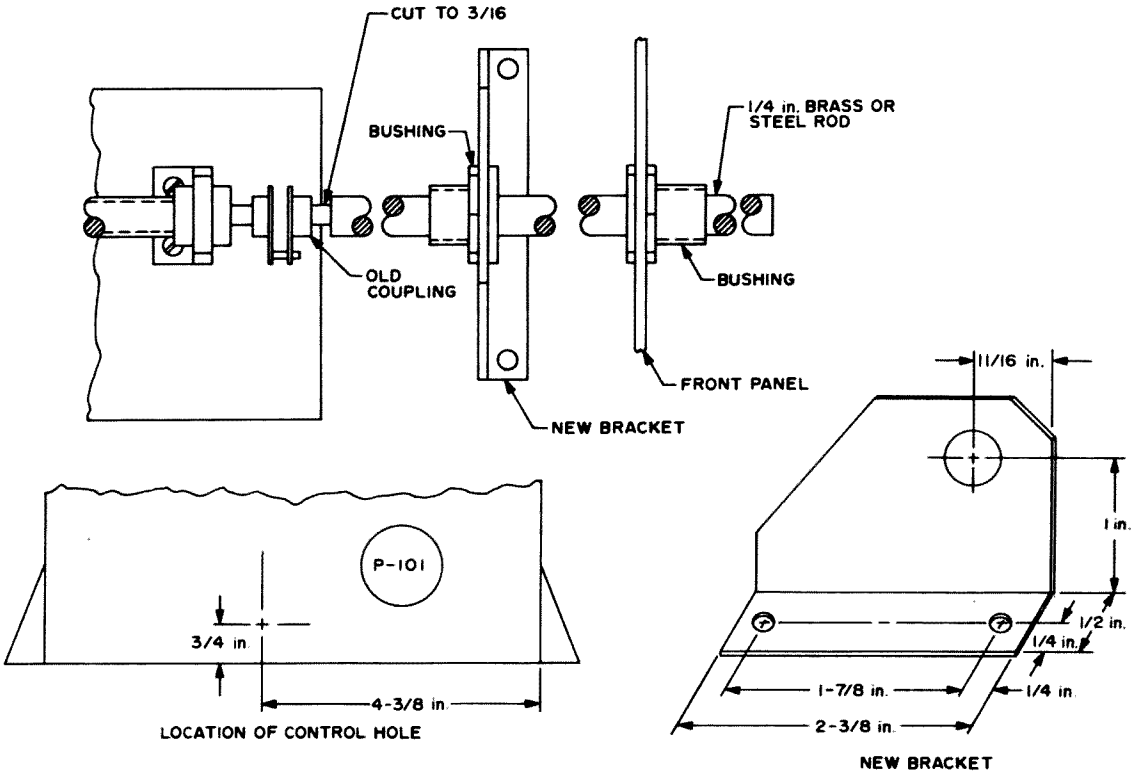

Fig. 16. Mechanical details of manual peaking control.

the hookup are shown in Fig. 15.

Microphone volume was originally controlled by an aneroid barometer attached to a potentiometer. This is the large can or cylinder directly behind the crystal switching relays and is marked R142 on the schematic. Remove and disassemble it, extending the connecting leads to the front panel. Extract the potentiometer and remount it on the front panel.

To avoid making a number of connections to the front of P102, I decided to connect S2 through the relay rack compartment directly to the coils. This involves removing the phenolic covers and cutting a small hole in the top cover to clear the leads. Removal of the back cover involves some unusual arrangements. There are two wires going through it which must be unsoldered to effect its removal. Instead I extended the slit through which they ran to the bottom of the plate. This can be done with a hacksaw blade or small file. Wires were then soldered to the side of the relay coil not having a jumper to one of its own contacts.

Power leads are attached in the same manner as to the receiver. The A1–A2 switch allows the transmitter to be keyed A2 with its internal oscillator with the microphone PTT connection. For A1 or A3 it is left in the A1 position.

Manual RF Peaking

Unless a 28V, 6A power supply is available, automatic tuning is not recommended. The supply shown in Fig. 6 is not capable of handling the load of the tuning motor, but will feed the keying and crystal switching relays nicely. Manual peaking of the rf stages requires relatively little conversion.

Begin by locating motor B101. It is mounted by six screws which attach through the main chassis to standoff posts. Remove all six screws and the motor–brake assembly. Cut and tape all three leads connected to it. Using a splined wrench remove the drive coupling from the end of the asssembly. Also remove the two center standoff posts and reinstall them on the chassis in their old location. Drill a hole

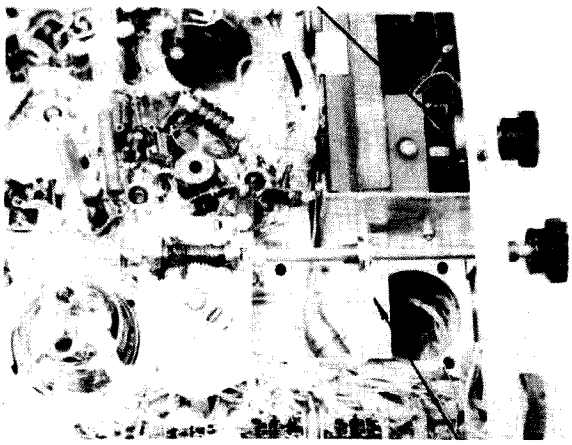

Fig. 17. Installation photo of manual tuning feature.

to accept an old potentiometer bushing as shown in Fig. 16. The ¼ in. shaft must be cut down to 3/16 in. on one end. If no other method is available, one can put the rod in the chuck of a ¼ in. drill and hold a file against it until the proper diameter is reached. The method is crude, but works. Mount another bushing in the new bracket described in Fig. 16. Install the entire assembly as shown in Fig. 17.

Locate K107. Remove the jumper going from the coil to one of its own contacts. This frees the PTT system to work without the tuning mechanism.

In operation the transmitter is peaked up by observing the output. A relatively small excursion of the tuning knob covers the entire 2 meter band.

Relative Output Indicator

The output indicator is shown in Fig. 18. The diode can be almost any rf type. Output is about 1–2V.

Afterthoughts

The speaker in my receiver was mounted in the top of the cabinet over relay K201 and V207. It was necessary to remove these items to obtain clearance for the speaker and transformer. Others may wish to use another mounting location or speaker size.

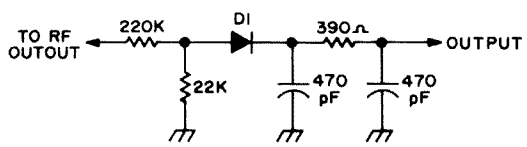

Fig. 18. Output indicator.

Figure 19 shows some of the connector layouts and a few miscellaneous dimensions which may be of help in the conversion of these units. All diagrams are front views.

Many of these ARC-3 units have been sitting unused in warehouses for some time. Therefore components may have aged considerably and it may be necessary to repair the units before they are converted. A borrowed 28V high-current supply can be used to operate the equipment in its original configuration long enough to assure proper operation. If problems are encountered, be suspicious of the capacitors, as they are wax units and often leak or short. This preliminary checkout is highly recommended. It can save many headaches later.

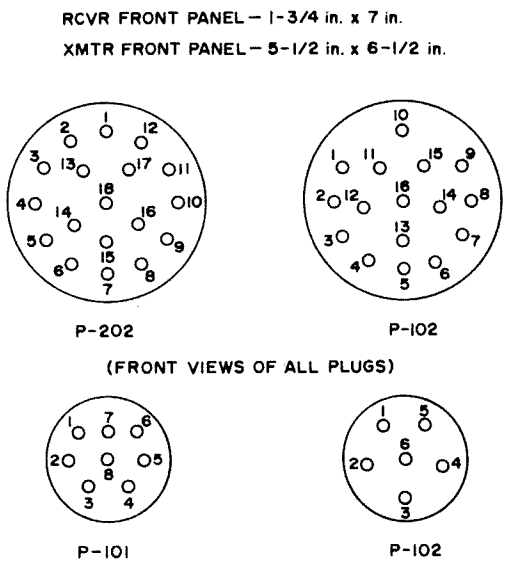

Fig. 19. Connector pin diagrams.

The transmitter was originally set up to cover the entire 100–156 MHz band. By peaking the rf chain in the center of the 2 meter band, considerably more output is available than for the wider band coverage. The tech manual gives complete information on the procedure.

Thanks to Paul G. Branson, Richard Patisaul (WA4ARQ), and Thomas F. Evans for their assistance and encouragement in this work.

BLOWN FUSE INDICATORS For LOW VOLTAGE

At first glance the unit to be described would appear to be strictly a luxury, but use it once, and you'll wonder how you ever got along without it.

It is a well known fact that individually fused circuits not only give increased protection to equipment, but simplify troubleshooting by isolating the defective circuits. But it also means more fuses to check when troubleshooting.

In ac equipment it is a simple matter to connect a neon bulb directly across each fuse; thus, when all is well all bulbs are out (being shorted by the fuse). When a fuse blows, the bulb is placed in series with the load and, glows (without allowing enough current flow to damage the defective circuit). A look at Fig. 1 will make this operation clear.

I "borrowed" the idea from a piece of military gear several years ago, and have used it ever since. Many hours have been saved by knowing exactly which unit to check when something "went south."

Many times I have wished that such a system could be applied to the mobile rig, but since the 6V in my VW (or the 12 in your Cadillac) will not light a neon bulb it seemed out of the question. Then a light came on in the think department. How about incandescent bulbs? Theory could not find a flaw in the idea (at least not my limited theory) so it was decided to give it a

practical test, using a sealed beam unit from a headlight as a "load." It worked!

The values used were selected for easy calculation, but the theory will hold in any

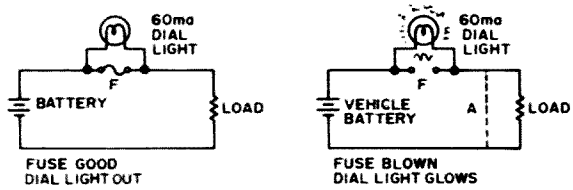

Fig. 2.

case. Assume, for example, a 6A load. The next higher rating of fuse is 10A, which should give adequate protection. Now, connect a 60 mA pilot lamp across the fuse. If all values are considered to be exact (of course they never are, but this is theory) our circuit may now conduct 10.06A before the fuse blows. If a short develops at point A in Fig. 2, the fuse will blow, but the lamp will merely have its normal brilliance, announcing to one and all that F1 has blown. If the short is only momentary, the bulb will be placed in series with the load, but application of Ohm's law will show us that our 6A load has a resistance of only 1.0Ω, while the 60 mA bulb has a resistance of 100Ω, thus most of the applied voltage will be dropped across the bulb, and it will still light.

This method worked out so well on the mobile rig that it was also applied to the entire automobile, with all the bulbs installed on a single panel just below the dash.

Unless you have a large supply of pilot light sockets and jewels on hand, this would at first appear expensive, but there is a sneaky way around this. Bulbs mount nicely in a grommet set into a hole, and coating them with a special paint made for putting orange parking lights on older model cars makes a very attractive installation. In the event the bulbs tend to creep out of the grommets, a drop of Duco cement applied to the bulb and grommet will cure this, and replacement is so seldom that connection may be made by soldering directly to the bulbs.

Addendum To The W1PLJ Counter

One of the best amateur radio-oriented frequency-counter articles, in my opinion, was published in *73* magazine in February 1968 by W1PLJ.

Although the W1PLJ counter was designed around RTL logic, considered to be obsolete for new designs by many engineers, it still has much to recommend it in terms of price and performance. RTL is a logic form that was first to be IC-implemented and so has a few features upon which the newer IC logic families have improved. RTL is, however, still probably the most durable IC logic form in the hands of the beginner. Mistakes in wiring or inadvertent shorting of leads together in testing are usually forgiven by RTL. Also, since most hams are used to devices being turned "on" by a voltage input, RTL is easier to understand than the more sophisticated "current sinking" logic forms (DTL or TTL).

The original counter article was written in such a way as to allow the builder to choose from a number of ICs (Fairchild or Motorola), and so IC pin numbers were not given. As such, the article was not *really* a construction article.

I began construction of the W1PLJ counter by the hand-wired method used in the original article. After making two of the

Decade Counting Units (DCUs), the task seemed to have no end in sight. This much of the counter was a "shot in the arm," however, as I could hook the DCUs up to +3.6V, +150V, and a pulse generator, and watch them "count" and display. In order to simplify the repetitive job of constructing DCUs, a PC board was taped up, as shown in Figs. 1 and 2. This board makes building the counter much easier, combined with another simplification. The neon indicator systems were pulled off old Hewlett Packard AC4A tube type DCUs (the ones that had four 12AU7s in them). These are often available in surplus stores, and really speed up the mechanical implementation of the display, since the numbers and so forth are all there. Similar DCUs that are suitable were made by Berkeley and Detectron, but the H.P. units were the easiest to use in my opinion. I personally wouldn't pay much over $3 for an old AC4A (without tubes) since the price of ten NE2s is only about $1 and that of the least expensive "nixie" (Burroughs B5750) is only $6.75.

The particular transistors used on my DCU boards were 2N720As which I happened to find a "good deal" on, but the 2N1893s or 2N3877s recommended by W1PLJ will also fit the board. The ICs chosen for the PC board *do* cause some restriction, but those specified are the least expensive choice for eight RTL inverters in two IC packages, and two dual JK flip-flops. (The Motorola HEP parts will be somewhat

more expensive than the Fairchild μA and Motorola MC numbers they replace, but the HEP parts are more generally available.)

The other simplifying modification of the counter was the use of MC780P decade counter ICs. These ICs were unavailable when W1PLJ wrote the original article. They make the frequency standard divider section much easier to wire and eliminate any divider adjustments. The MC780P costs about five cents more than two MC790Ps, which were used as the two lowest frequency decades in the original counter, but are well worth it in simplification. The new divider section is then as shown in Fig. 3.

Completed counter.

The original counter article did not show a power supply for the crystal standard, and so a new crystal oscillator and regulated supply for it was designed to fit my particular needs. The use of the LM305 IC-regulator very simply accomplishes the job of obtaining a small amount of regulated +15V needed for the crystal oscillator and buffer. Note that a 200 kHz surplus FT241 crystal was used in this version of the counter. While it may be argued that the 1 MHz crystals (being AT cut) are more stable than the crystal used here, the 200 kHz FT241 is quite adequate for the four-place accuracy of *this* counter. These 200 kHz crystals are available from JAN crystals for $1.75 plus 10¢ postage (*Jan Crystals, 2400 Crystal Drive, Ft. Myers FL 33901*).

The finished counter as packaged is shown in the photograph. This counter has been immensely helpful in routine lab work for setting oscillators to frequency *quickly*, and many other tasks. The main advantage of a counter is not its great accuracy, but rather its great *speed* of reading out frequency. Since the counter does all the work, for instance, you can connect it to an oscillator that you are slowly heat-cycling and look up only occasionally to log the temperature and frequency. In short, it is a gadget every experimenter ought to have.

Ken W. Sessions, Jr. K6MVH

Constant-Currant Charger for Ni-Cads

...Lets you charge your batteries the way the manufacturer would want you to.

If you own a hand-held transceiver with a nickel-cadmium battery pack but you don't have a charger, you've probably been going about the recharging task the hard way – connecting a low-voltage dc source to the battery, monitoring the current drain with a milliammeter, and using a pot to increase the applied current to the required rate as the battery gradually becomes charged. That's an effective system, of course, but it requires one heck of a lot of attention if you want the battery up to snuff at the end of the period.

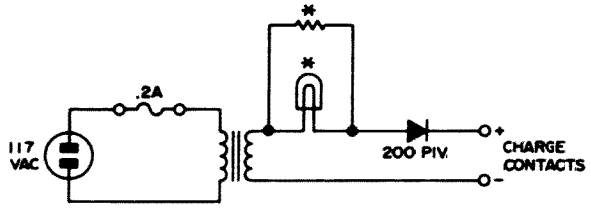
As the battery regains its state of charge, it will tend to draw less and less current, always seeking a state of balance between the applied voltage and the battery potential. When you charge the hard way (as most of us HT owners have), it's very hard to keep track of the time on charge at the right rate, which does make it extremely easy to end up overcharging – and destroying some of the cells in the battery.

Since ni-cads should be charged for 15–16 hours at 10% of their milliampere-hour rating, the monitoring and adjustment process can keep you hopping and be a real drag. The obvious solution is to attack the problem the way Motorola does with its factory-made charging systems – that is, to use a charger whose output current remains constant over the full 16-hour charging period.

Building such a charger is an incredibly simple job. All you need are transformer, small lamp, resistor, and a diode. Since the resistor–lamp combination (and the battery under charge, of course) will determine the current drain, the pair should be selected according to the requirements of your particular battery.

A 28V transformer is right for virtually all Motorola ni-cads, which are themselves typically just over half this value. In most cases (where the battery has a capacity of a quarter of a milliampere-hour or more), the lamp itself should be a 28V type. The charger circuit is shown in Fig. 1.

The resistor should be selected to draw 25–30% of the current drawn by the lamp. You can determine the values experimentally if you have a junkbox that is fairly rich in lamps and resistors. Place a milliammeter across the charging contacts (when the battery is NOT in the circuit) and measure the dead-short current. It should be exactly twice the value of your battery's 16-hour



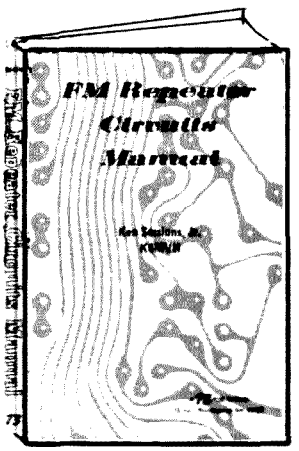


Fig. 1. Constant-current charger circuit for 15V ni-cad batteries. Caution: Don't try to charge mercury batteries with this charger or you'll have battery all over the walls of your shack!

REPEATER CIRCUITS MANUAL

If you're into FM, you'll want to have this incredibly complete manual of FM circuits. You don't have your own repeater yet? Well, you've been thinking of it . . . admit it. Some fellows even have gone so far as to have a repeater in their car so they can extend the range of their hand units!

This book, over 300 pages long, has just about every circuit that you could possibly want. Many of these have been published elsewhere, but many haven't, too. And you can go out of your mind trying to find a circuit when you want it . . . so here they are, all in one handy place!

ONLY $6.95 ppd.

Table I. Lamp and Resistor Values for Popular Motorola Units

Radio	Batt Rating	16-hr Charge Rate	Resistor	Lamp Current
HT-200	500 mA-hr	50 mA	120Ω	70 mA
HT-220	235 mA-hr	25 mA*	270Ω	40 mA
HT-220 OMNI	450 mA-hr	45 mA	180Ω	70 mA
HT-100	70 mA-hr	7 mA	100K	**

*Charge for 15 hours at specified rate.
**Use a GE type B2A neon glow lamp.

charge rate. The approximate values for resistors and lamps suitable for use in chargers for most popular Motorola HTs are shown in Table I. If you use these values, be sure to double check the short-circuit current as indicated above before connecting the battery. It's possible you'll have to make some slight modifications in the resistor values, since those shown were derived by calculation rather than by an empirical process of in-circuit measurement.

When the battery is placed in the circuit (in series with the lamp), the voltage across the lamp drops to approximately half its shorted value, which will also halve the current; thus, if the short-circuit current measures 100 mA, the current will be 50 mA when a 15V battery is connected.

Now that you've got the problem of building the charging circuit licked, you'll have to use some real ingenuity to get the battery charged. The mechanical problems associated with charging Motorola batteries are mind-boggling. There's just no simple way to connect test leads to the batteries. Motorola chargers are form-fitted to the battery so that when the battery is placed in the "pocket," a set of contact pins on the bottom of the charger connect with the battery at the right spot. But if you don't have a form-fitting battery holder, you'll just have to be clever about it. I made up a little wooden box into which the battery fits rather nicely, and installed a couple of screws at the bottom for contact pins. But it would have been easier to simply buy a new Motorola charger. If you have any ideas, I'm sure the rest of 73's readers would like to hear about it.

National City, CA 92050

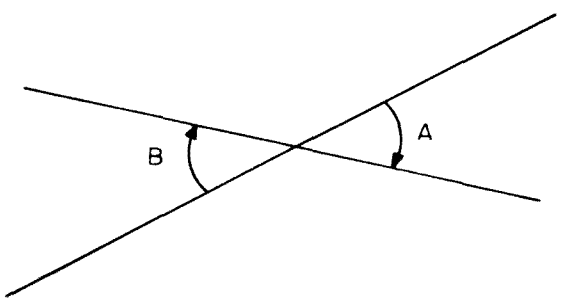
The ESM/1 Transceiever

The ESM/1 emergency signaling device is a self-contained pocket-portable unit that has a range of up to ten miles in fair weather daytime conditions. The device is solar powered and operates in the noncoherent light band. The emission is of the CW mode. Its dimensions are four by five inches, and about a quarter inch thick. Obviously it is solid state, very solid, with no moving parts of any kind. It must be very state-of-the-art you say? No indeed, this device appears to be at least twenty years old, and is probably World War Two surplus. So what is the trick? It's very simple; it's all done with mirrors. But this is a very special mirror, so let's take a look at how this device works and how we can put it to work for us.

Theory

At some time or another everyone has probably reflected the light of the sun with a small mirror. However one problem develops if the light is to be directed to a spot a great distance away. Because of the inverse square law and a few other things, the spot of light in the distance usually becomes invisible to the operator and the means of aiming it are lost. The following discussion will explain what has been done to provide a simple and effective means of aiming the spot of light at distances of several miles.

It's easier to show than tell, so take a look at **Fig. 1**. Here we have two intersecting straight lines. The thing to notice is that the two opposite angles marked A and B are identical. This comes from a theorem in geometry, but can be seen by inspection. For those who are interested in this, a high school geometry text should clear this up.



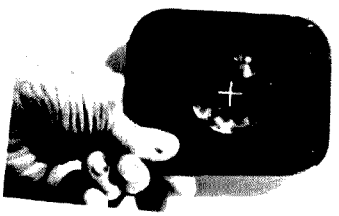


Fig. 1. Equal Opposite Angles. Note that angle A is the same as angle B.

The mirror consists of a sheet of glass with a reflective surface on one side that reflects from both front and back. This thin reflecting surface has a cross shaped opening in it that allows light to pass through the center.

With these facts established, it is possible to explain the operation of the mirror in **Fig. 2**. Starting at the light source (the sun), the light travels both the dotted and dashed line to the mirror. At the surface of the mirror, most of the light is reflected to the object of interest. However, because of the small opening in the surface, some of the light also travels the dotted line through the mirror and strikes another surface (not a mirror). The light is reflected from this surface in the solid line back to the mirror, much weaker in intensity because of the nature of the surface. Since the back of the mirror is also a silvered surface, the solid line is reflected on to the eye where it is seen as the image of a cross as projected on the surface. In the final leg of the light's travel, we focus our interest on the object. The light that makes up the image of the object travels the solid line to the eye. Since there is an opening in the mirror, the object is seen as it would normally appear, but through the hole in the mirror. It is in this configuration that proper aiming is achieved. If this explanation is not clear, the next section should clear it up.

Operation

At first glance, the instructions on the

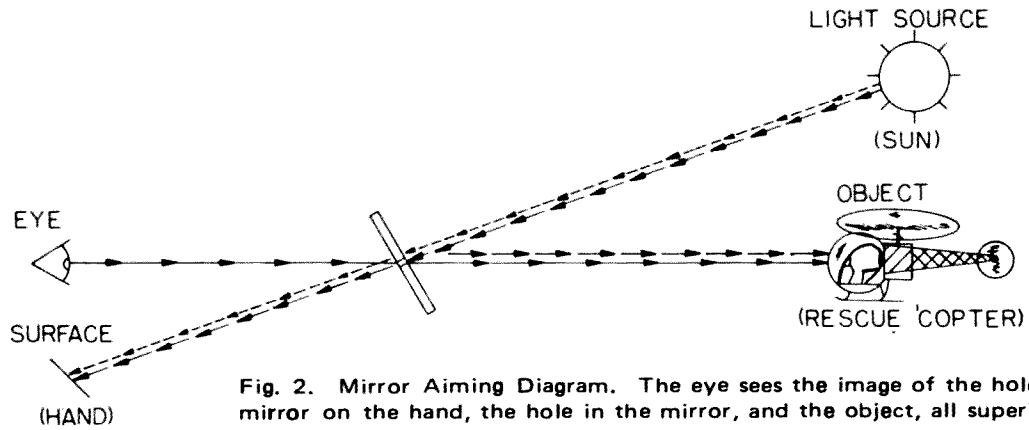

Fig. 2. Mirror Aiming Diagram. The eye sees the image of the hole of the mirror on the hand, the hole in the mirror, and the object, all superimposed on each other.

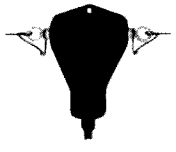

mirror are not very clear, so some instruction is in order. The first step is to hold the mirror in the sun so that the cross shaped image appears on some surface, usually your hand. Now move your eye around so that the image on your hand is visible in the mirror. Your eye should be about two or three inches from the mirror. As soon as the cross is located, line it up with the cross shaped hole in the center of the mirror. What you see in the distance through the hole in the mirror is where the light is aimed. It is simply a process of lining up the three things; the image of the cross, the cross shaped hole, and the object. Keying can be done by using slow or fast passes over the object to form dashes or dots, respectively. A little practice is required here.

The uses of this device are obvious wherever a highly portable temporary means of communication is required – so long as the sun shines. Microwave or laser paths can be checked for line of sight clearance by this simple method before actual installation of equipment. Since no license is required, anyone can use it. And, if someday you find yourself sitting in one of those little rubber boats with nothing but ocean all around, this mirror may save your life!

LOW COST TRANSISTOR RF

Semiconductor progress in the past few years has been nothing short of amazing. The transistor has evolved from the 20 milliwatt wonder to a replacement for the 6146. Although basically aimed toward industry, this rapidly advancing technology can be of use to the amateur. One particular field of interest to the ham is that of *rf* power, where often today the transistor proves more economical and practical than the tube. Through proper transistor selection and well-designed circuits, the transistor must no longer take a back seat to the tube for economy.

Transistor Selection

The many merits of the transistor over the tube are well known to every amateur who took part in the great transistor vs. tube disputes a few years ago. But economy was seldom added to the list; "bargain" tubes and cannibalized television sets gave the tube man the edge. The story has changed, though, and today *rf* transistor list prices look a little more appealing. In the $5 and under price range a number of good rf transistors are presently available, as shown in the chart in Table 1. This cross-section of popular types cannot only give you an idea of how much performance to expect for a given amount of money, but it can help with the selection of a type for any desired application.

Two electrical specifications are given on the chart. Both are useful in the selection of transistors, yet often misunderstood. Pt, as might be expected, refers to power. Technically it stands for "the total nonreactive dc power input to all terminals". From this definition it would seem that Pt is the total dc input, and therefore the maximum power input of the transistor. Not so, however, for transistor technology defines power *output* as *negative power input.* In other words, the Pt rating refers to the amount of dc power input *minus* the output power. This corresponds to the plate dissipation of a tube, for it is a rating of the amount of power that can be safely radiated as heat, expressed in watts.

The second rating on the chart, the Ft, concerns the frequency limit of the transistor. "The frequency at which the small-signal foward current transfer ratio extrapolates to unity", the manuals claim. Translated, that's the frequency at which no gain can be realized from the transistor. Of course, we are concerned with frequencies well below this rating, for in the interests of economy a transistor *rf* stage should have reasonable gain, hopefully at least 8 or 9 db. Exactly how far below this frequency the transistor will operate at a moderate efficiency is often difficult to judge.

This "highest practical frequency" depends mainly upon the percentage of efficiency wanted. The 2N2102, for example, has an Ft of 120 MHz, but 50% efficiency cannot be obtained in operation above 10 MHz. Output *is* possible above 10 MHz, but the low efficiency involved makes it impractical from the technical standpoint. At the same time, other transistor types with similar Ft's can operate well above 10 MHz with 50% efficiency. For most HF types a figure of ten percent of the Ft gives a rough estimate of operating frequency. Further specifications of the types listed on the

chart, often including practical frequency limits, can be found in manufacturers' guides and manuals. More on obtaining these later.

Assuming that a transistor running class C well below its Ft has a 50% efficiency (which, in most cases, is true), it is obvious that the dc power input of the transistor can safely exceed the Pt. In fact, at 50% efficiency, the dc input can be as much as *twice* the rated Pt. This should be apparent, for if half (50%) of the input is "lost" as output, the remaining half can be safely dissipated.

There is one major disadvantage to increasing a transistor's dc input beyond the rated Pt. If, for some reason, the antenna or load shorts or opens, destruction of the transistor is likely. Having a power input above the Pt and no means of power output, secondary breakdown would take place in the transistor, and failure would be immediate. For the sake of safety most transistor circuits are designed to have the dc power input not exceeding the Pt rating of the transistor. For then, even if the load is interrupted or shorted, the transistor will still be capable of dissipating the entire input.

Another caution concerning maximum power input considers the effect of heat on the transistor. Most Pt ratings are rated at a case temperature of 25° C, or about 77° F. Higher temperatures rapidly reduce the effective Pt. At 30° C, or about 86° F, some types lose as much as 75% of their rated Pt. Although room (ambient) temperatures usually won't be this high, the heat generated by the transistor itself can easily raise the case temperature above 35° C. As the temperature rises the transistor becomes incapable of dissipating the unused input, and thermal runaway takes place.

Destruction of the transistor by thermal runaway can be prevented by the heat sink. With an effective surface area much greater than the transistor's case, the heat sink can radiate enough heat to maintain a safe case temperature. It is important to remember that the heat sink is not meant to *increase* the Pt above its rated value, but only to allow the transistor to dissipate heat and still be capable of its full Pt.

Manufacturers:
MOT: Motorola
GE: General Electric
TI: Texas Instruments

If more than one manufacturer is shown, price indicated is the lowest, and manufacturers are listed in order of increasing price.

Type	Pt W	Ft MHz	Mfg.	Remarks, Features, Similar Types
2N706	1	200	MOT, GE, TI	Very popular HF/VHF osc. and low power amp. TO-18 case. Similar: 2N706A, 2N706B, 2N708
TIS44	1	200	TI	New "Economy Model," plastic case. Similar to 2N706
TIS48	1.2	500	TI	"Economy Model," plastic case. Excellent for VHF. Similar: TIS45, TIS46, TIS47, TIS49, TIS51, TIS52
2N697	2	100	MOT, TI, RCA, GE	One of the earlier rf transistors. Slightly outdated for rf use, but still useful and inexpensive.
2N1491	3	380	RCA	HF/VHF amp. Similar, more power and cost: 2N1492, 2N1493
2N2218	3	250	TI, MOT, GE	Similar, same price: 2N2218A, 2N2219, 2N2219A
2N3118	4	250	RCA	1 W out on 50 MHz.
2N2102	5	120	RCA	HF osc. and amp. Good performance to 10 MHz. High voltage (Vcbo=120V) and tolerant of current surges. Economy version: 2N2270
2N3053	5	100	RCA, MOT	Low cost HF to 10 MHz. Similar: 2N2405
2N3866	5	800	RCA, MOT	One of the best values available for VHF/UHF osc. and amp. 1 W out on 432 MHz.
40392	7	100	RCA	Useful to 12 MHz. Special flanged case
2N3553	7	500	RCA, MOT	Popular HF/VHF power amp. and UHF osc. 3 W out on 144 MHz. Similar: 40280, 40290
2N2631	8.75	200	RCA	An easy 7.5 W out on 50 MHz.

The Circuit

Efficient, clean-sounding transistor *rf* begins in the oscillator. Remember one basic rule: the transistor oscillator is a low power device. Tube tricks, such as 40 watt oscillators, just don't work with transistors. As the power to the oscillator is increased, clean keying and frequency stability are quickly lost.

Shown in Fig. 1. is the typical Pierce transistor crystal oscillator. Two components are of note, base bias resistor R1 and collector tank L1. R1 should be selected for the best keying characteristics. A 5K or

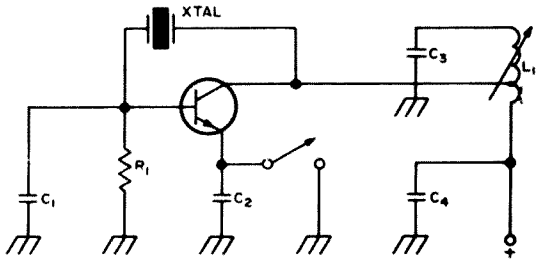

Fig. 1. Typical Pierce crystal oscillator circuit. C_1: feedback capacitor; C_2, C_4: rf bypass capacitors; C_3; output tank capacitor; R_1: base bias resistor (see text); L_1: output tank coil (see text) usually ferrite.

10K pot can be wired in during initial experimentation, adjusted, measured, and then replaced with the nearest fixed-value resistor. The value will usually be in the vicinity of 3K. Values shown in published circuits will seldom require adjustment. L1 should similarly be tuned for the highest output that is consistant with good keying and stability. Even if the oscillator will not be keyed, as in a SSB rig, these adjustments should improve stability.

Stable oscillation in vfo circuits is more difficult than in the simple crystal oscillator. The cost, though, of a simple vfo compares with the price of a few rocks, and the versatility of variable frequency is well worth the extra effort. The Clapp circuit is almost universally used, and for best stability should be well shielded. Many fine vfo designs have appeared recently in 73.

The vxo, or variable frequency crystal oscillator, is a good compromise between the crystal oscillator and the vfo. Shifts up to 25 kHz are possible from a single crystal with rockbound stability.

The simplicity of the typical transistor driver stage is yet another good reason for low oscillator input. Fig. 2 shows all that is actually necessary – an extra tank circuit, transistor, bypass capacitor, and bias resis-

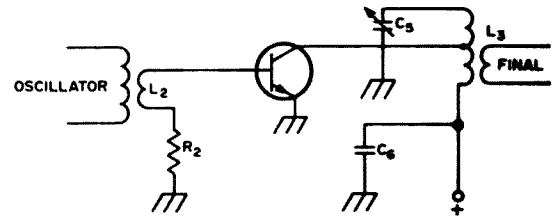

Fig. 2. Typical transistor driver stage. L_2: oscillator link; L_3: output tank coil (see text); R_2: base bias resistor (see text); C_5: output tuning capacitor (see text); C_6: rf bypass capacitor.

tor. In many cases the bias resistor will not be needed, as many transistors are capable of efficient "zero bias" operation. If needed, its value will be very low, and a small (100 ohm) pot can be used to adjust it for maximum power output, as explained above. Unlike the oscillator tank, output coil L3 is usually air-wound for higher efficiency, necessary because of the higher power level found in the driver. Therefore, tank tuning is done by capacitor C5, also tuned for maximum power output.

The selection of the transistor type for the driver is more critical than many builders realize. A type should be chosen that is *incapable of overdriving the final amplifier.* The use of a higher power unit than necessary "cut back" to a low power level is dangerous, and often costly, as meters or lights are usually needed to monitor the drive.

Completing the *rf* line, Fig. 3 is a simple transistor final. Notable here are the paralleled transistors. While some may frown on paralleling in the output stage, it remains an inexpensive method to increase output. An attempt should be made to find two transistors of the same type with similar

in-circuit characteristics. Collector current, Ic, is the most important.

Link coupling is shown in the final, as in the other stages, for interstage coupling. Tapped coils can also be used, although with adjustment, links prove more effective.

Bias resistor R3 resembles the driver resistor R2, and all comments apply. This value is not critical, as the resistor serves only to raise slightly the stage's efficiency by creating class C operating conditions.

The final is almost always tuned for maximum output rather than Ic dip. C7 is simply adjusted for maximum meter or light indication, depending on the type of indicator used. The Ic should be monitored during the initial tune-up, to warn of excessive current.

See the references at the end of the article for a list of recently published transistor *rf* circuits.

Obtaining Information

Perhaps one of the most useful all-around guides to semiconductor products is the Allied Electronics Industrial Catalog. Specifications and prices are given for thousands of current types. It can be obtained free on request from Allied Electronics, 100 N. Western Ave., Chicago, Illinois 60680.

Information can also be obtained from the individual companies. Most transistor manufacturers distribute for a few cents product guides or free application notes. For several dollars complete specifications can be found in the large technical manuals.

Transistor *rf* is here to stay. Take advantage of the low cost *rf* available with transistors – today.

NONLINEAR RESISTORS

Hank Olson W6GXN
P. O. Box 339
Menlo Park CA 94025

E=IR, or so Ohm's Law says, and we generally accept Herr Ohm's word for it. But there is a fairly large class of resistors for which Ohm's Law doesn't hold true: that is, for which a given voltage change *does not* cause a proportional current change. Such resistors are called nonlinear resistors.

"What, resistors that don't obey E=IR? It sounds like an enemy plot to upset our electronics defense industry," bellows the angry citrus county ham. Well, no; there's no plot; in fact, read on, old patriot. We'll see that nonlinear resistors are very useful to our electronics industry.

In a minor way, nearly every resistor is a nonlinear one. That is, every resistor has *some* variation of resistance with temperature. If current is passed through it, power (I^2R) is dissipated in the resistor, which changes the temperature of the resistor and thus its resistance. However, most resistors used in electronic circuits are designed to minimize resistance change with current, so that the assumption that each one has a constant resistance is a good approximation. The newer metal-film resistors bring the concept of a noninductive, linear resistor very close to realization.

The types of nonlinear resistors we'll be concerned with here are light bulbs, thermistors, Thyrite varistors, and similar devices. The light bulb is often called a barretter, a category which also includes small electrical fuses when used as circuit elements.

Let's take the light bulb first, since it is the most familiar to most of us. If we plot a curve of voltage versus current as was done in Fig. 1 (for a small 120V Christmas tree lamp), one immediately can see the nonlinearity of the device. The E-I plot of Fig. 1 is typical for light bulbs, and several important facts can be observed about it. The light bulb has a positive resistance coefficient; that is, as current increases, the resistance *increases*. Also, one will notice that (for normal temperature environments, where humans and electronics operate together) the greatest nonlinearity occurs at only a few percent of the normal operating voltage of the lamp.

Several other facts can be learned by more careful measurement. First, the lamp

JEFF-TRONICS

4252 Pearl Rd., Cleveland, OH 44109

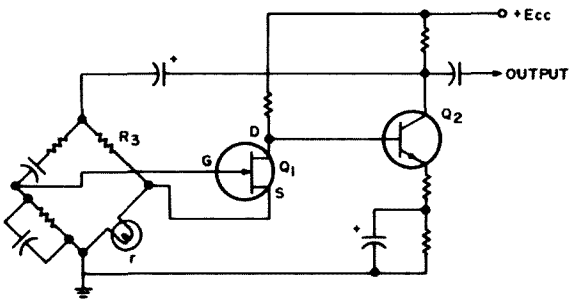

Fig. 2. The light bulb as a nonlinear amplifier as used in the Wien bridge oscillator.

has a time constant; that is, it will follow only slow changes in current. For our 120V bulb of Fig. 1, this time constant is of the order of one-half second. Secondly, at any point on the curve, if we shine a second incandescent lamp (operating at its nominal 120V) directly on the lamp under measurement, the measured current will decrease.

Perhaps the best known application of the light bulb as a nonlinear resistor is its use in the popular Wien bridge audio oscillator, as shown in Fig. 2. The left side of the bridge provides *positive* feedback to the gate of Q1, allowing oscillation to occur around this two-stage circuit. The right side of the bridge provides *negative* feedback to keep the amplitude of oscillation constant.

If the audio oscillator is initially operating satisfactorily (in class A), a change of operating conditions which increases out-

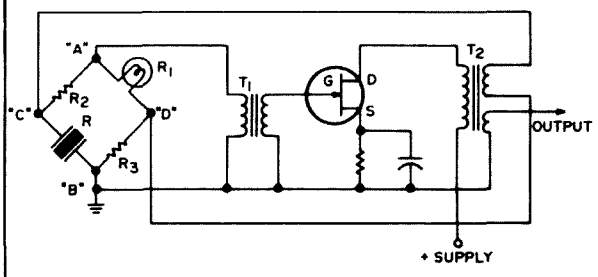

Fig. 3. A lamp as a stabilizer in the Meacham bridge crystal oscillator.

put will increase the audio voltage across R3 and r. The increase in voltage across r increases the resistance of this nonlinear resistor, which decreases the gain of the Q1 stage, restoring our original operating condition.

There is one consideration in Wien bridge design, however, that sometimes

isn't appreciated: The time constant of r must by large compared to the period of the lowest frequency of oscillation. This is necessary so that the resistance of r is only dependent on the rms value of output voltage, and does not vary at the audio

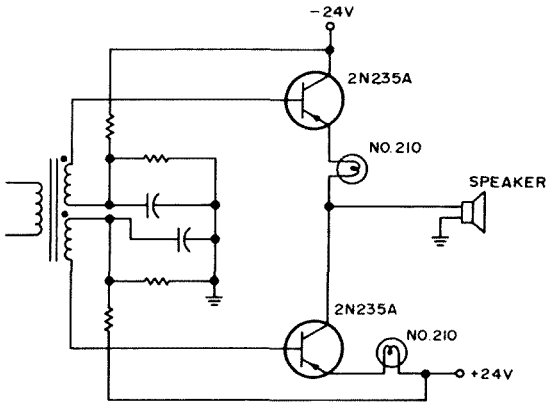

Fig. 4. Two lamps in a pseudo-complementary output stage.

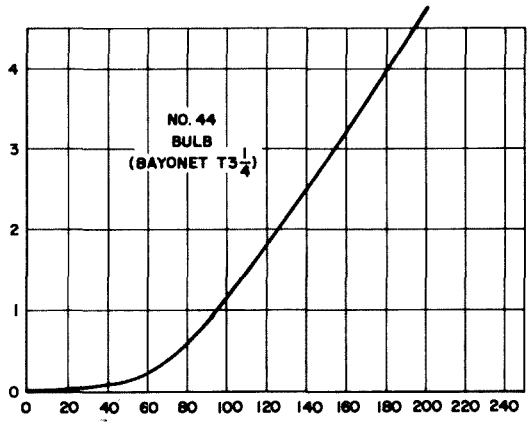
frequency rate. Bulb time constant can be a problem at 10 Hz, the lower range of some audio oscillators; this is one of the reasons that (large) 120V 6W bulbs are used in many audio oscillators.



Another oscillator which uses a lamp as a stabilization device is the Meacham bridge crystal oscillator. The elementary form of the Meacham bridge is shown in Fig. 3. Since this oscillator is a narrowband device, transformers can be used for matching and phase inversion.

The bridge is balanced when the point-to-point ac voltage is zero. In perfect balance, the Meacham bridge will not oscillate. But when a slight unbalance is present, typically 1%, oscillation occurs. The lamp is positioned in the bridge in such a way that an increase in its resistance will adjust the bridge *toward* balance.

The best choice of bridge values occurs when $R=R_1 = R_2=R_3$. Since R (the series resistance of the crystal) is determined by the crystal supplier, we have very little control of this parameter. Starting with R, we must then find a lamp which offers the same resistance (R_1). The resistance R_1 must equal R at a point on the E-I curve of the lamp where resistance is changing rapidly and this value of E x I should also be approximately the value of power we expect to dissipate in the crystal in operation.

Since, in the previous two examples, the light bulb was used as a measuring device (measuring rms voltage or current), why couldn't it be used as an rf monitor? Lamps *can* be used as barretter elements at frequencies where their inductance is small compared to their resistance. The resistance of the element is then measured with an audio frequency bridge, the rf circuit (including the barretter leg) being decoupled by rf chokes and capacitors.

Because of the "loop" construction of most lamps, the inductance of a lamp is a severe limitation on usefulness at higher frequencies. The instrument fuse, however, because of its size and axial construction, is much more easily used as a barretter element. The 3AG or 8AG fuse is easily placed in a coaxial system for measurement of power. For years, standard 1/200 amp and 1/100 amp Littlefuses have served as barretter elements in power measurements up to 4000 MHz.

Fig. 5. A selection of E-I plots (cont.)

So far, we have seen lamps used as stabilizing elements in oscillators and as elements in bolometers for power measurement. A similar use of lamps is in the application of current limiters or fuses. In many circuits which may be subject to expensive failures, lamps may be used to slow down destructive runaway currents, and then "open," fuse-like, if the runaway continues uncontrolled. One such application is in push-pull or pseudo-push-pull transistor output amplifiers; Fig. 4 shows two lamps in a pseudo-complementary output stage. In this particular design, separate positive and negative supplies are used, and the speaker is direct-coupled. In case of a failure of one output transistor, the speaker is protected, as one of the bulbs will open in about 0.1 second.

In order to be able to use lamps as nonlinear circuit elements, one must know, in fair detail, their E-I characteristics. E-I plots on common lamps are not generally available, and so must be plotted by the user. A selection of E-I plots is presented in Fig. 5, as measured by the author. The curves in Fig. 5a through 5j all show somewhat similar shape. The fact that some seem to display a sharper "break" in slope is apparently due to details in the form and mounting of the lamp filament.

A (rare?) exception to normal lamp behavior was found in one old telephone-style bulb. The E-I plot of this unit is shown in Fig. 6. This unit is apparently an old carbon filament type, and its response came as quite a surprise.

The curves presented in Figs. 5 and 6 should be taken as "typical" for their particular types; individual units can vary somewhat.

The second nonlinear resistor that we shall examine is the thermistor, a device not so familiar to most hams as the light bulb. Actually, there are many thermistors in use by hundreds of amateurs across the country, but they probably don't think of them as such. The thermistors generally used by hams are those which were designed for TV sets with series heater strings, but which are used in high power final amplifiers as plate parasitic suppres-

Solid State Reliability
Very Low Power Consumption/Low Cost
80 Decibel Volume

This tiny buzzer is unique in its compact size and high sound output. Just right for devices requiring audible signals. . .intercom sets, timers, test apparatus, automotive warning signals, alarm clocks, sensors and other portable or battery-powered products. Solid state. . .no moving contacts, no arcing, electrical interference or rf noise. Easy to connect and install. Weight: ¼ oz. Sound output 400 Hz. Measures .88" x .61" x .39". Current consumption only 15 mA at 1.5 volts. Two models: 1.5–3 VDC and 12 VDC. Engineering evaluation sample available for a $5.95 handling charge. Send check or money order. GATED CALIBRATED MARKER GENERATOR
K-OSC-G1 Wired & Calibrated $45.50

K-OSC-G1K Kit all parts and case (less batteries) $35.50
The K-OSC.-G1 is a gated generator on and off 3 times per second making it easily recognized on today's crowded bands. Frequency – 1 MHZ, 100 KHZ, 50 KHZ, 25 KHZ. Accuracy – High Precision 1 MHZ xtal. .001%. Gate time – 3 Pulse per second. Harmonics – up to 200 MHz. Output – Square wave, 3.5 PP. Electrical Description – All solid state, printed circuit on 1/16" glass board. ICs 2 gates, 3 dividers, and 1 transistor. A ceramic trimmer allows zero-beating WWV. Physical description – The K-OSC.-G1 Generators are small, structurally rigid yet light-weight instruments which are designed for portability. The instrument is enclosed in a 3 color vinyl covered metal & plastic cabinet. Dimensions are 2 3/8" x 5 1/8" x 6"

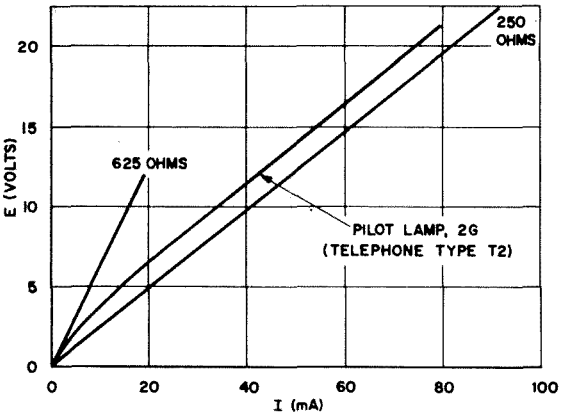

Fig. 6. The E-I plot of an old telephone style bulb.

sors. The General Cement Glo-bar type 25-912 is typical for this use, having a resistance of 20Ω hot and 250Ω cold. The variation of resistance with temperature (not with dc, since there is a coil in parallel in parasitic suppressor service) makes little difference in this application.

Thermistors – that is, thermally sensitive resistors – are made of metallic oxides of manganese, cobalt, and nickel which have been sintered at high temperature. They are ceramic-like in their physical characteristics, and they are very stable electrically. If one uses a thermistor with very small current passing through it (not enough current to dissipate a significant amount of power in the device) we find that it has a temperature versus resistance plot like that in Fig. 7. From this plot, the obvious use for a thermistor is in the measurement of temperature; and many *are* used for that purpose. The thermistor once calibrated, measures temperature by itself; unlike the thermocouple, which needs a temperature reference.

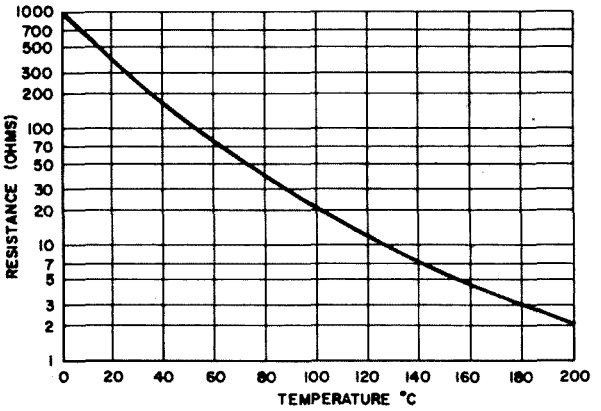

Fig. 7. The temperature versus resistance plot of a thermistor.

Temperature compensation is another use for thermistors. This can be as simple as using a low resistance thermistor in series with a relay coil to prevent its drawing too much coil current when very cold. An example of temperature compensation of a phase shift oscillator is shown in Fig. 8. Of course, the oscillator in Fig. 8 could also have been frequency-compensated with negative-temperature-coefficient ceramic capacitors.

If larger currents are used in the thermistor, so that power is dissipated in it faster than heat can be conducted or radiated away, a different situation exists. In this case an E-I plot similar to Fig. 9 applies. To the right of Vm, in Fig. 9, the thermistor has a negative resistance coefficient, due to the heating effect of current. In this negative slope region, thermistors may be used in circuits as nonlinear resistors having the opposite slope as lamps.

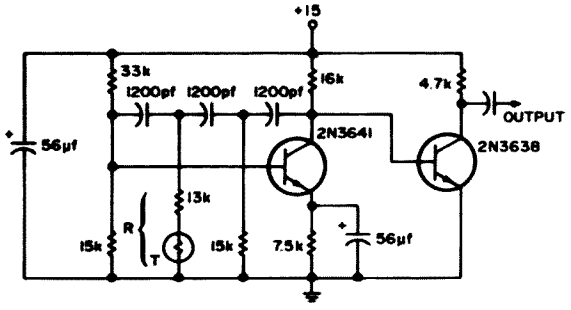

Fig. 8. Temperature compensation of a phase shift oscillator.

In Fig. 2, if R_3 is made a thermistor and r is replaced by a common resistor, the Wien bridge oscillator can be made to work just as well as originally. Since thermistors which are generally available have time constants of one second up to several minutes, the requirement that the nonlinear element in the Wien bridge respond only to the rms value of audio oscillation is easily met.

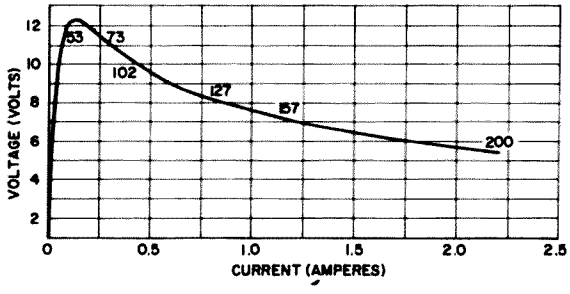
The Meacham bridge crystal oscillator (Fig. 3) is also operable using a thermistor in the lamp leg of the bridge (R_1), if one also reverses the sense of either transformer in the circuit.

Like lamps and fuses, thermistors are used as barretters for the bolometer method of measurement of radio frequency power. The thermistors used are very tiny, so have little inductance and fit conveniently into transmission lines.

Vacuum tubes have heaters or filaments that behave similarly to lamps as to their E-I characteristics. That is, until a tube heater or filament comes up to a visable red or orange color, its resistance may be only a fraction of its nominal value. This means that when we plug in our tube-type receiver, the initial current drawn from the line may be several times the normal operating value. Since the thermistor has the opposite (E-I) coefficient to the tube, one is often put in series with the line to limit initial inrush current. This is especially true in series-heater TV sets, where the previously mentioned General Cement 25-912 is used. Not only is inrush current limited by such a thermistor; but since the tubes warm up much more slowly, the tube heaters are subjected to far less thermal stress, resulting in better tube life.

Thermistors are not *special* or *rare* devices; being made by GE, Veco, Fenwal, Ferroxcube, and others. Several manufacturers' types of thermistors are obtainable from Allied Radio's mail order service, making them available easily anywhere in the U.S.

The last type of nonlinear resistor we will cover is the Thyrite varistor. This element is rather an old one as electronic devices go, having been introduced about 1930. The Thyrite varistor was first developed for use as a lightning arrestor, and is a relative of the coherer – that ancient detector of waves in the ether.



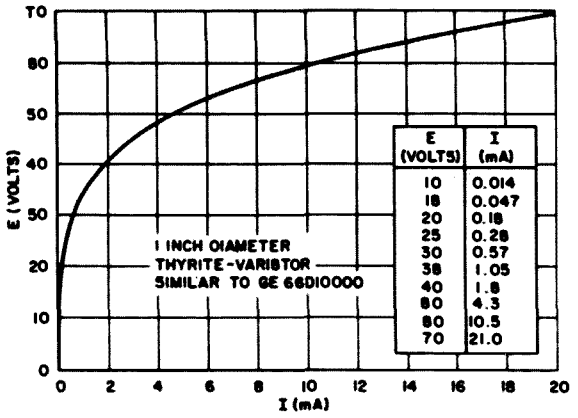


Fig. 9. The E-I plot of a thermistor using larger currents so the power is dissipated faster than heat can be conducted away.

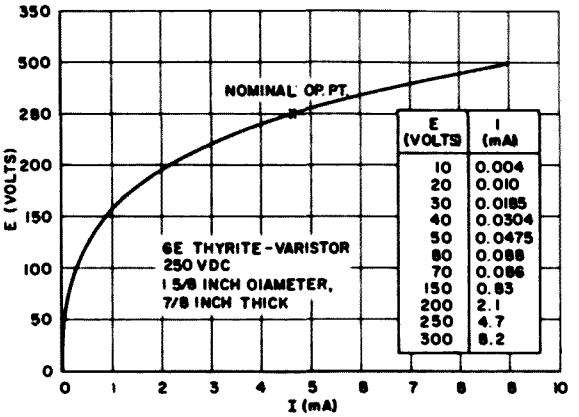

Fig. 10. The E-I plot of a Thyrite varistor.

Thyrite displays a negative coefficient of resistance versus voltage, like a thermistor, but differs in a very important way. The resistance value of the Thyrite varistor does not take seconds or minutes to be established, after application of voltage. This means that the Thyrite varistor fills the need for a "fast" limiter, one which will respond at the ac rate. This fast response shouldn't come as any surprise, since the stuff *was* designed for lightning!

Figure 10a shows an E-I plot of a representative Thyrite varistor, and Fig. 10b shows another higher-voltage type. Both curves show identical curvature even though the plots have quite different scales. This agreement is due to the fact that Thyrite follows the relation $i=Ae^{3.54}$. What this means, simply, is that if one doubles the voltage across *any* piece of Thyrite, the current through it will increase roughly twelve times.

Thyrite is useful any place we wish to attenuate transient voltage spikes, whether they come from the ac line or are internally generated by circuit components. For example, Thyrite varistors are widely used across relay coils to control the inductive spike that occurs when the relay is deenergized.

Figure 11 shows a simple power supply that uses three of the Thyrite varistors of Fig. 10a to protect the rectifiers. The two varistors across the transformer secondary are to protect against transients that are coupled from the ac line. The third varistor is to damp the inductive spike which occurs when the supply is turned off and the choke field collapses. These particular Thyrite varistors have been used extensively by the author because of their convenient size, voltage rating, and *low price*. They are available for 49 cents from Red Johnson Electronics, 3311 Park Boulevard, Palo Alto, California (who also sells the 16 VA transformer shown in Fig. 11 for $1.89). The fully protected supply can thus be built for about $10.

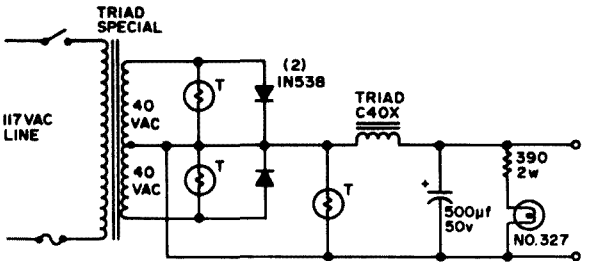

Fig. 11. A simple power supply using three Thyrite varistors to protect the rectifiers.

Like thermistors, Thyrite varistors are available through the Allied catalog and so can't really be considered *odd* devices. Although Thyrite varistors are historically old devices and are somewhat bulky, their use costs little and can save many dollars worth of expensive semiconductors.

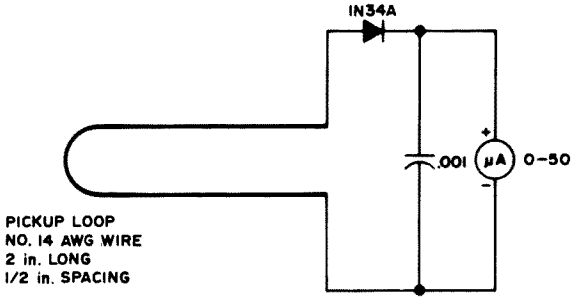
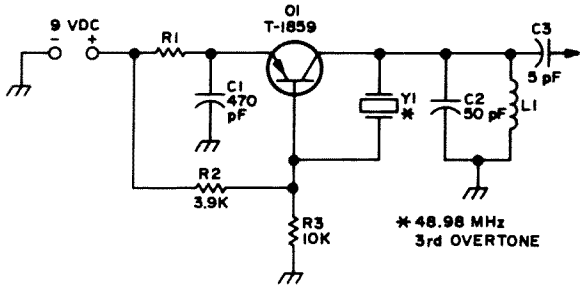
CIRCUITS, CIRCUITS, CIRCUITS...

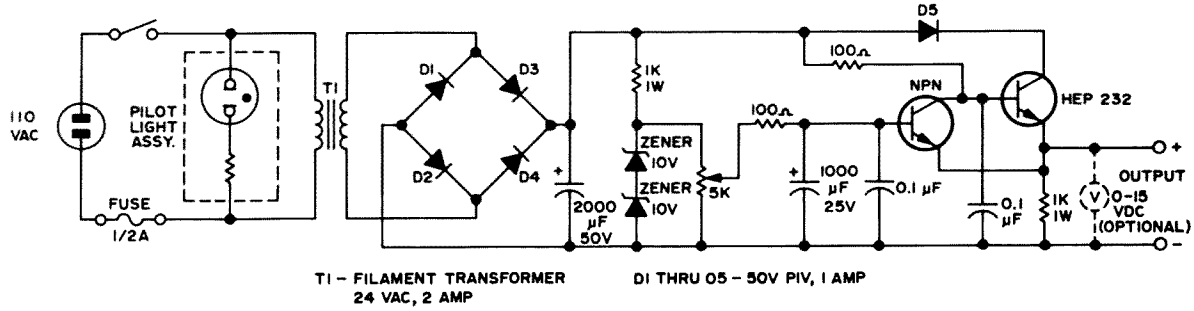
The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.



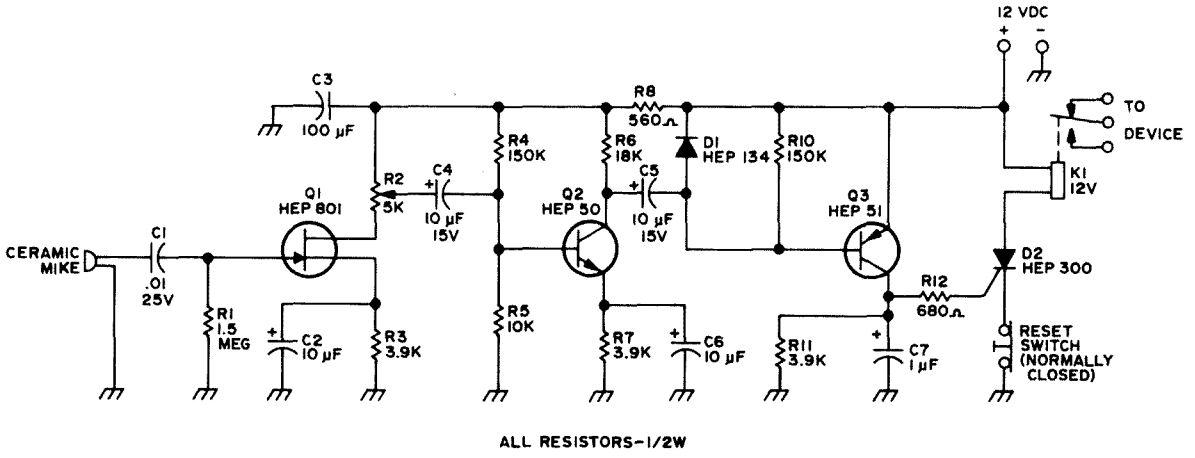
Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.



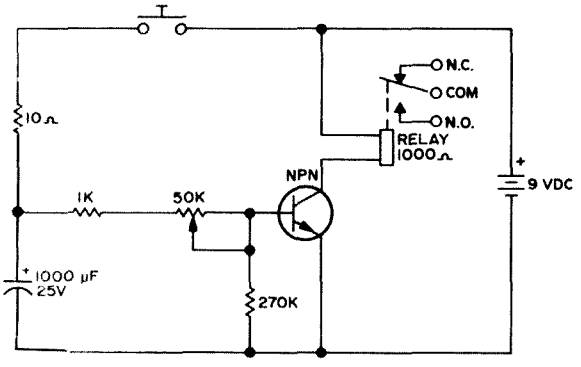
S-meter for the "Sixer," from 73, July, 1961, designed by K5VMC. The circuit is applicable to the "Tenner" and "Twoer" as well. It consists of an inexpensive 0–1 mA meter and a single transistor meter amplifier. Half-scale deflection is obtained on a signal strong enough to quiet the background hiss as compared to about 1/4- to 1/3-scale on a 20,000 ohms per volt meter or a VTVM reading the voltage drop across the plate dropping resistor.



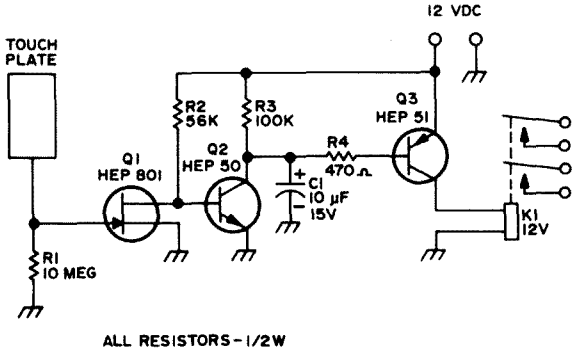
Motorola MFC6000 monolithic functional circuit, in an audio amplifier application. Circuit courtesy of Motorola Functional Circuits catalog.



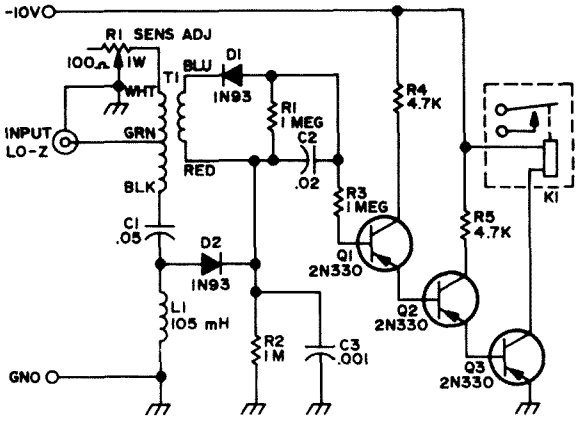
RF Sniffer designed by W5JCB, from an article by K5JKX in 73 Magazine, December, 1960.



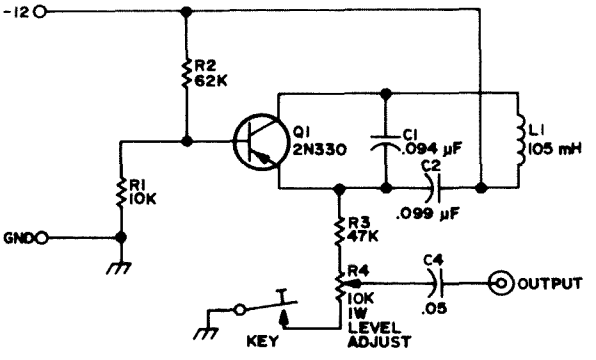
Crystal oscillator for aligning receivers, reprinted from FM Magazine in FM Anthology I, available from 73 Magazine for $3.00.



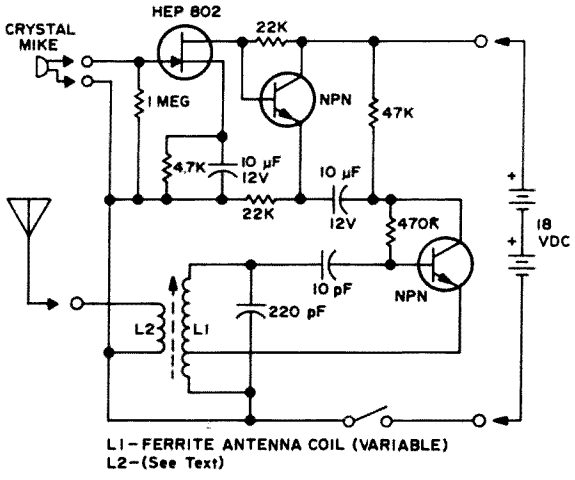
Power supply for 0–20 volts up to 1A. Run that tape recorder, transistor radio, pre-amplifier, or charge a battery. Circuit courtesy Calectro Handbook (50¢), 400 S. Wyman, Rockford IL 61101.



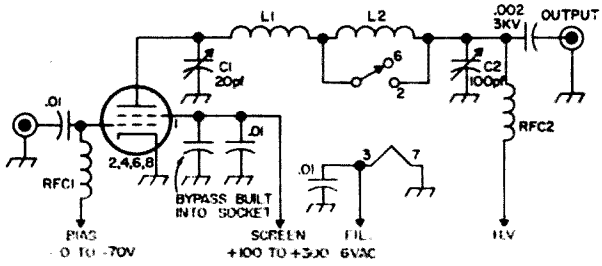
Sound activated relay. Control any circuit with a clap of the hands or any sharp sound. The circuit remains activated until manually reset. It has adjustable selectivity. Circuit courtesy Motorola HMA-33 "Tips on Using FET's."



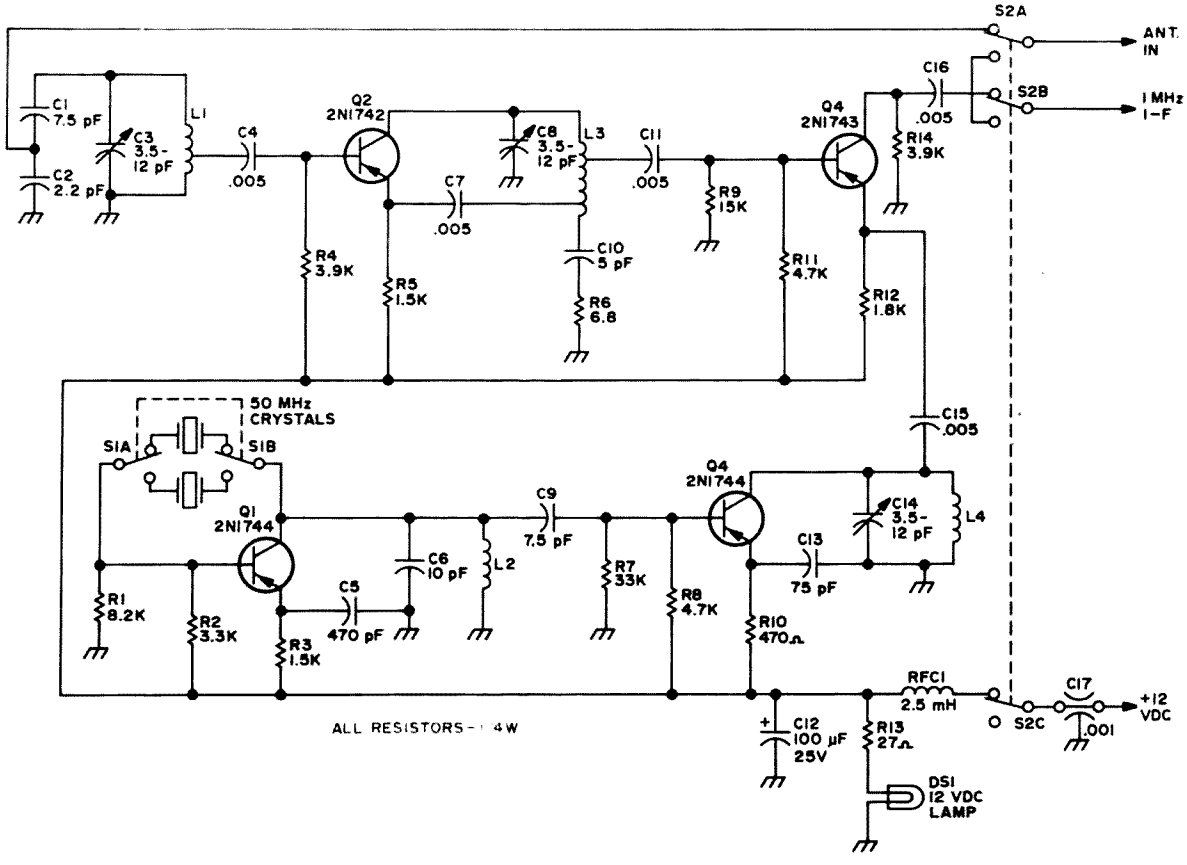
Timing switch, 10 to 100 seconds. No off switch needed since circuit draws only 1 µA when not used. Great for darkroom, 10 minute timer for identification, repeater shutdown for windy talkers, etc. Q1 is a Calectro K4-506 transistor. Circuit courtesy Calectro Handbook.



Touch switch. This switch is operated by body capacity . . . just touch the plate to operate the relay. How about this to turn the rig on and off? You can use a latching relay, time delay relay, stepping relay, to do just about anything. Circuit courtesy Motorola HMA-33 Tips on using FETs, available free from Motorola, Department 73, Box 20924, Phoenix AZ 85034.



This single-tone decoder has a high degree of selectivity, stability and reliability. Designed by Bob Mueller K6ASK, it and its companion encoder below appeared in FM Magazine in January, 1968. The article is reprinted in FM Anthology I, published by 73 Magazine.



K6ASK single tone encoder (see above).

AM wireless transmitter. Useful for baby-sitting, sick watch, intercom, and plenty etc. Circuit courtesy Calectro Handbook. L1 is a variable antenna coil, ferrite, Calectro D1-841. L2 is four turns of hookup wire wound on top of L1. Q2-3 are NPN silicon transistors Calectro K4-507.

4CX250 amplifier for six and two meters, using single pole switching. By K1CLL, from 73 Magazine, April, 1966. Simple modifications by Fritz Hervey K4ETZ [forget the 6 meter coil and use smaller PA tuning capacitors, Class C bias and a grid tank] allow 10W drive, 200–250W out with enough air on the anode. Amplifier should have a screen clamp tube with G2 supply bled down from high B+ for best results, says Fritz . . . and he suggests a TV power transformer with a doubler for cheap 1.2–1.5 KV power.

Car radio converter, by WA8ALL, from FM Magazine, June 1967, reprinted in 73's FM Anthology I. There's no text or anything with the original, either. . .just the circuit.

REPEATER BULLETIN

As a reader of 73 you may be interested in the newest FM bulletin . . . the Repeater Bulletin. This magazine is published by 73 Magazine just for the users of repeaters, particularly in the New England and Eastern New York areas and it carries news of activities of the repeaters covering this section of the country.

In addition to news from the repeater clubs the Repeater Bulletin will carry maps showing the coverage of the repeaters, discussions of the problems faced by repeater groups . . . discussions of frequency coordination, of functions being added to repeaters, of whistle-on, of tone burst, of touchtone, and continuous tone coding and decoding . . . antennas . . . coverage of repeaters . . . hints for mobile installations . . . cross-band links . . . circuits of value to both users and repeater owners . . . a bibliography of the articles being published on FM . . . discussions of new equipment being brought out . . . ideas for repeater development . . . new frequencies . . . 220 plans and developments . . . 450 repeaters and their problems . . . problems faced by FMers in other areas of the country worthy of consideration in the North East . . . news of club meetings . . . symposiums . . . conventions . . . dinners . . . auctions . . . swapfests . . . and other social events . . .etc.

The Repeater Bulletin is available absolutely FREE to every repeater user in the New England and Eastern New York areas . . . just send in an application form for qualification indicating that you are an active user of FM. If you live outside of this area (if you are unable to use any New England repeater), the Repeater Bulletin is still available, but at a subscription price of $2 per year.

If the Repeater Bulletin is successful, it is always possible that its coverage may be extended to cover more of the country or that other regional editions could be published. We have all of the facilities here at 73 to turn out publications such as this quite economically, so we may be able to provide a communication medium if it is needed in other areas.

The Bulletin is in a large format (8½" x 11") and runs 24 or so pages per month.

Repeater Bulletin Subscription Order Form

☐ I am actively using a New England Repeater and wish a FREE subscription.

☐ $2 is enclosed for a one year subscription to the Repeater Bulletin.

Tappan NY 10983

SIMPLE DIODE CONTROLLER

Some time ago I had a problem with the night light in my entrance hall. The little bulb kept burning out. The next step was to install a larger bulb. This was not too bright. About this time, I pulled the Variac from the workbench and determined what constituted a satisfactory setup. But it seemed foolish to keep a 1 kW Variac tied up in controlling less than 10W of power. The simple circuitry used in the solution to the problem should appeal to the reader, not only for light control, but for many other ac-dc applications. Light control, soldering iron heat control, and speed control for small universal ac-dc motors are but a few examples.

Most experimenters are acquainted with the fact that with a small current load, the dc output of a capacitor-input type of filter will soar to relatively high voltages. Advantage is taken of this fact in the simple circuit under discussion. The circuit, shown in Fig. 1, has only seven parts: three capacitors, three inexpensive slide switches, and a silicon rectifier. Cost for the whole thing? Three or four dollars, if you buy all new parts.

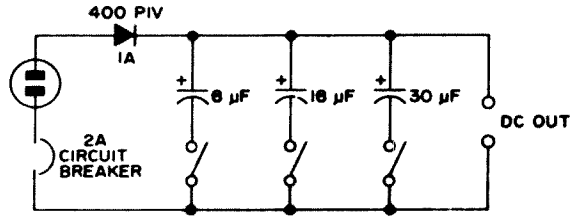

Fig. 1. Schematic diagram.

A diode will rectify the ac at 120V and convert it to pulsating dc. Due to a small loss through the silicon rectifier, the output voltage will come out close to half of what is fed into it. If the ac is 120V, the pulsating dc will be close to 60V. When read on a dc voltmeter, the true DC voltage will be roughly 54V (60V due to half-wave rectification x 0.9). If this voltage is then applied to an incandescent lamp, the actual input wattage will be approximately 25% – that is, half voltage at half current. I say "roughly 25%" since my calculations have been simplified and do not include

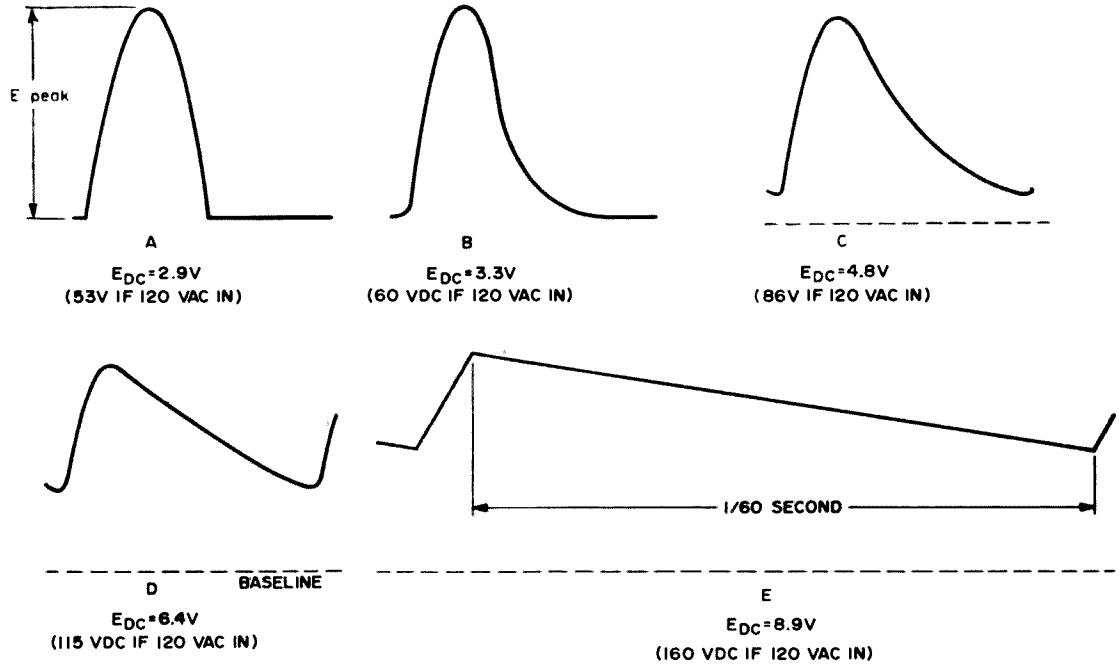

Fig. 2. NOTE: These waveforms and dc voltages shown are for purposes of illustration only. The actual dc output voltage from the unit diagrammed is much higher, running from a minimum of 53V to a theoretical maximum of 168V dc when fed with 120V. These CRO pix illustrate how a condenser-input type of filter will give more "boost" with varying amounts of capacity when feeding a fixed load.

the resistance-vs-temperature factor of the tungsten filament. If we introduce a small capacitor at the input to the filter, this will boost the pulsating dc output voltage slightly. The actual voltage will depend principally upon the size of the filter capacitor and the current requirements of the load being supplied. Through the application of three capacitors of 8, 16, and 30 μF, we can obtain eight discrete steps throughout the range of the controller. That is, we can use the output of the silicon rectifier with 0 - 8 - 16 - 24 - 38 - 46 or 54 μF of input capacity. This will give a wide range of control for small loads, any nonreactive type of load, up to a maximum of 50W with the normal line voltage of 120V ac being fed into the input. Strictly ac types of electrical equipment, such as a transformer, cannot be fed from the controller, since the output voltage is pulsating dc.

A look at the oscilloscope will show how this variation in voltage is effected. In Fig. 2 the unaltered half-wave of the rectified and unfiltered dc shows above the baseline. As more capacitance is added across the rectifier output, the valleys between the alternate pulsations of dc start to fill in. A close examination of the last CRO presentation will reveal that the rectified dc pulse does not return to the baseline, where it would touch zero. Instead it remains at a much higher average level, due to the storage effect of the capacitors.

With a 120V ac input, this would amount to 169V. For this reason, it is always wise to start the controller with zero capacity, and then add small increments of capacity. When the characteristics of a particular load become familiar, the controller may be turned on to a predetermined setting.

My main use for this simple controller is the setting up of certain light intensities, plus heat control for a small soldering iron. There are no theoretical limits for a device of this nature, but economic realities limit its function to controlling powers up to 50W. Beyond that range, other devices begin to come into their own. However, the simple diode controller does a very effective job up to 50W or so, and does so with low cost and simplicity.

Some Harmonic-Suppression with a Low-Pass Filter

or

How to Eliminate THE Major Source of TVI

TVI is predominantly caused by radiated harmonics. Particularly the 14, 21, and 28 MHz bands cause harmonics that fall into TV channels 2–6. This was my problem also and it was fairly easy to cure it.

I was stuck with TVI a long time because most literature listed several sources of TVI and I was not able to classify my source. As for remedy, I didn't want to spend any money on a trial-and-error basis. But eventually, it became obvious that the problems were antenna-radiated harmonics, and that the cure would be a low-pass filter.

To make triple-sure, I borrowed a grid-dipper and fiddled myself a standard pick-up coil, which I hooked up to my dummy load. Then I tuned the spectrum while I switched to 10, 15, and 20m bands. And there they were – harmonics. 57 MHz, 63 MHz, 85.5 MHz. And when I checked the TV channel frequencies, I really understood why I had to have TVI. I estimated the power level of my harmonics by switching my pickup coil over to a little transistor oscillator, on 27 MHz, which puts out 30 mW, rf. This indicated that my harmonics at 57 MHz were 5–15 mW on

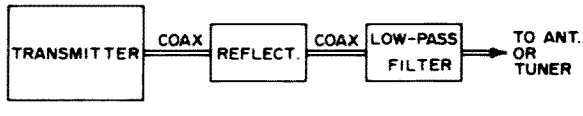

Fig. 1. Diagram of filter set-up.

14 MHz and 15–30 mW on 28 MHz. This would be 35–45 dB down compared to my transmitter output, which is 100W. I looked through the specs of a few transmitters in this price and power bracket and found specs to read around –40 to –45 dB for harmonic suppression. So I was in the ballpark with my measurements.

The Filter

Surprisingly, none of the handbooks emphasized the urgent need for a low-pass filter to eliminate harmonics that go to the antenna. One would expect this to be just as standard as the transmitter itself. After I obtained my results on the cause of my TVI, I purchased a good quality low-pass filter. Good design, I should really say, because it has a few features that are essential if you want the filter to work efficiently – and which not all available low-pass filters have.

Two most essential tuning adjustments are the input- and output-impedance adjustments which are an asset if you want to avoid excessive power loss on transmitting and receiving. (See Fig. 1 for schematic.) Another important feature is the three tuning adjustments for channels 2-3-4, 4-5-6, and 7 & up. The filter manufacturer claims a suppression of 70 dB minimum for frequencies of 45 MHz and higher. This put my harmonics from 40 dB down to 110 dB, which is about 1 nW in my antenna. It eliminated all my TVI problems except for channel 2 on my own set, but then – my TV antenna is right below my groundplane.

This filter is a Radio Society of Ontario design and is manufactured by Taylor Communications, Uxbridge, Ontario. The price is $24.95 Canadian. It is not cheap, but it *is* effective.

How to Tune the Filter

The success of the filter depends on how well you tune it, and to do this you must have an swr bridge or some kind of reflectometer. The best way to set it up is as Fig. 2 shows. From your transmitter you should go through your reflectometer to the filter, from there to the antenna. Since the filter is designed to work in a 50–75Ω line, you have to use this type of coax for the interconnections. If you want to use a 450Ω open feeder you have to install everything between transmitter and tuner. Now, before you start tuning you also need a dummy load. With all the equipment hooked up as in Fig. 1, first adjust the input and output impedance of the filter. Tune C1 for a maximum *forward* reading on your reflectometer, tune C4 for minimum *reflected* on reflectometer. Repeat the adjustments several times. Your reflected power should be less than 1%, or below 1.2:1.

The next adjustments are to get maximum rejection of the interference frequency. To do this I turned on my TV set and switched it to the channel that I wanted to clear up. I increased the signal of the transmitter until the picture would get crossbars. Then I started to tune the related C on the filter in small increments. After each incremental adjustment I repeated the tuning procedure for CI and C4 to maintain the low swr. Since I did not have any TVI at TV channels 7 & up I simply adjusted this C5 for maximum *forward* deflection.

After tuning the filter according to this procedure, I eliminated TVI on channels 3, 4, 5, 6; only 2 remains somewhat a problem in my own house. Neighbors of mine who had TVI before do not have any at all. One chap with a color TV can merely see a faint change in color on channel 2.

You will find that you might not have the optimum filter setting when optimizing for one particular frequency. In my case, when tuned for 20m I found swr tuning was not quite maximized on 15m and somewhat more off on 10m. I set my filter

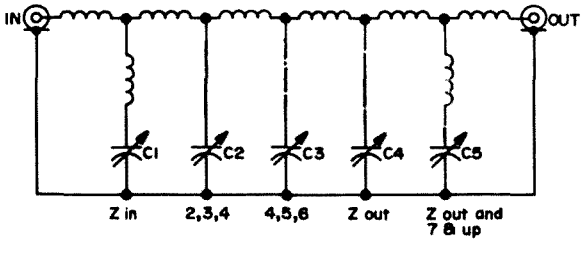

Fig. 2. Schematic of filter.

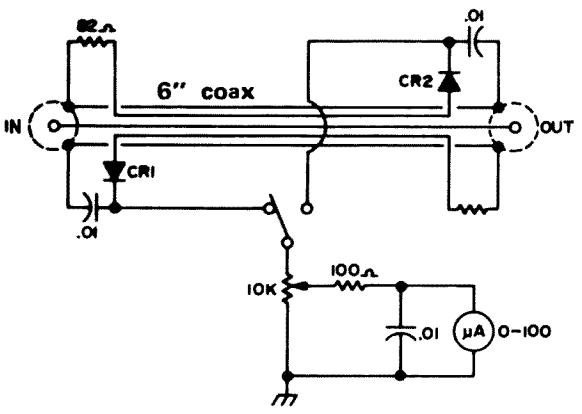

Fig. 3. Schematic of reflectometer. CR1 and CR2 are any matched pair of silicon or germanium diodes.

to compromise between the 3 bands. With a dummy load, reflected power on a compromise setting reads between 1 and 2% depending what part of the bands I use. Switching to my groundplane antenna, I am getting between 2 and 6% power reflected.

The Reflectometer

The reflectometer I used (Fig. 3) is a modified version, as the one listed above. As a conductor and pickup I used 6 in. of RG-8/U coax with two insulated wires pulled into the braid. This is less of a mechanical job than the original of W4BRS (73, Sept. 1967). As for the meter scale, I also calibrated it in "% reflected." This is more meaningful to me than swr.
Dial calibration based on a 100% meter scale:

Scale %	= SWR	= % reflected power (coax losses disregarded)
9	1:1.2	.8
20	1:1.5	4.0
33	1:2.0	10.5
43	1:2.5	18 5
50	1:3.0	25.0
60	1:4	36.0

The Dummy Load

This dummy load (See 73, Feb. 1968, WA6OBH) was built and I found it can take 80W rf for quite some time. However, I do not advise you to use motor oil for coolant, since its dielectric constant is much to low because of inorganic additives. ....VE3GSP■

HW 100... Adding the 400 Hertz CW Filter

Many operators like to work both CW and phone. The HW-100 is supplied with the SSB filter only. Heath states in the HW-100 manual that the CW filter can be placed in the rig, but at the cost of leaving out the SSB filter. This of course leaves the transceiver good for CW only. Many operators, like myself, operate both CW and phone, so of course I put in just the SSB filter. Being very human, I later decided it would be nice to have a narrow, 400 Hz slot for CW. This, of course, was realized after the rig was completed. I spoke with some boys who placed the CW filter into the *completed* HW-100, doing it as it is done in the SB-101. This is a herculean task in the completed rig, but it can be done.

After reviewing the circuitry, Fig. 1, and the method of mechanically performing the switching of either filter in or out of the circuit in the SB-101, I felt there must be an easier way to do it. The following modification is easier, faster to install, and *cheaper*. I spent 49¢ over the cost of the filter and a new matching panel knob.

Modification Procedure

Additional parts needed:

1. CW filter with mounting nuts.
2. Matching panel knob for HW-100.
3. Rotary wafer switch containing the equivalent of 3 SPDT contacts (Fig. 2).
4. New mounting bracket for filter. The old one can be redrilled, as I did, to accommodate the two filters as both filters are physically identical and the bracket for both filters is the same as the CW bracket alone, except for the holes being in different places.

Considering the frequent use of both filters at my QTH, front panel installation for the switching of the filters was needed. Since the mike will usually remain connected, access to the mike connector was of secondary importance.

The PTT mike connector, at hole M on the front panel, was moved to the left rear apron where the unused hole was enlarged to receive it. Additional hookup wire was used to lengthen the circuitry resulting from the move. The wafer switch was placed in the hole M. The CW filter was mounted on the filter bracket with the SSB filter. The two capacitors, C506 and C101 and the resistor R929 are not connected to the filter, only to the circuit board points as instructed in the HW-100 manual. The remaining connections of the capacitors and the resistor will be done on the wafer switch as in Fig. 2. Make sure the lugs of the phone jack at hole L does not contact the lugs on the wafer switch. Bend the lugs away as needed on the phone jack. All leads from the wafer switch to the filters will pass through grommet CA for neatness and ease of installation.

Ground connections can be made at any convenient point. R929 went to the ground foil of the modulator board. The

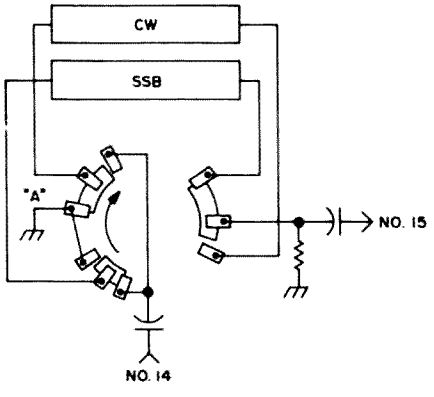

Fig. 2. Schematic/pictorial for CW and SSB filters in HW-100.

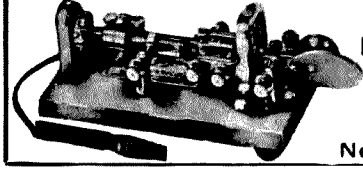

"A" ground (Fig. 2) I put to a bolt holding the modulator board to the chassis. Insulated wire was used and sleeving as needed to prevent unnecessary bare wire exposure.

I strongly suggest that if the original filter bracket is going to be redrilled as I did, that you remove the bracket from the rig, even though it means removing the VFO also. This little extra work will save a load of time, effort and possible expense in trying to find short circuits and/or resultant damaged components caused by those small bits of metal dropping into the works of the rig. Also do not try to get away with the grounding on the input side of the filter when not in the circuit. These filters have, I am told, bifilar windings. Because of the close coupling of these two filters, induced emf can be generated in the filter while not in use. This in turn will create its own field which will affect the filter in the circuit. This induced emf in the unused filter must be removed and is done so by grounding. You can count on this to hamper the filter qualities and to interfere with good receiver operation.

The advantage of this method of installation is that the front panel does not have to be pulled away from the chassis. This can be a big undertaking for the type of switching used in the SB-101 because the wires are short on the band and mode switches on the front panel of the completed rig. Besides, the purchase of the 2 slide switches and the mechanical linkages for the switching of filters as in the SB-101 will cost far more than the 49¢ I spent for my wafer switch.

CQ U.S. with PHONE PATCH TRAFFIC

Ralph Steinberg K6GKX

Dial one one zero on your telephone and a pleasant voice answers, "Operator." This is nothing unusual except when a phone patch is being arranged by a long distance operator for some serviceman to talk to his family from Vietnam.

Thousands of phone patches are beamed daily to the United States by MARS stations in Vietnam. Handling thousands of phone patches takes team work; the long distance operator, the overseas radio operator, and the station in the United States receiving the overseas calls make up the team.

It is fascinating to see at first hand how these operators work the long distance switchboards. The girls have boards with switches, jacks, and plugs. Each position has nine incoming and nine outgoing circuits and each operator is responsible for these circuits. If phone patching is in operation, each operator can handle nine calls at one time. To keep the calls moving smoothly, the operator always has another ready to talk when the preceeding call is finished. Usually, on phone patch operations, one operator will stay on the circuit until all phone patch operations are completed.

All phone patch calls are not just routine and many times the operator has difficulty in locating the person to receive the call. Frequently calls are for families living in small villages in mountain areas far from a long distance phone line. The operator will try to locate the nearest long distance phone so that the phone patch can be completed. Often company officials have assisted in locating hard-to-find parties, sometimes at all hours of the night.

Fig. 1. View of long distance telephone switchboard operations. Pacific Telephone Co. photo.

Fig. 2. Phone patching at MARS station K6WAH/AA6WAH. U.S. Army photo.

A serviceman in Vietnam was calling his family, and the long distance operator advised the father that she had a collect call from his son and would he accept the call. The father refused the call thinking someone was joking until the operator explained it really was his son on the line and the father then accepted the call. It was a happy and exciting event as this was the first call the family had received since the son left home to go overseas. They were unaccustomed to receiving phone patch calls, especially collect. On other calls proposals of marriage are heard several times a day. As one serviceman proposed, the sound of guns could be heard in the background.

Drama has an equal share in the phone patching. One call from a serviceman to his wife was never completed as she was among the missing in a plane crash. There are also calls to the families by the servicemen, explaining that they have been injured, but not to worry. One serviceman was talking to his wife and asked if the new baby had been born. When he learned that triplets were born, the telephone line went dead on his end. He had fainted.

The long distance operators are exceedingly interested in the phone patch work they are doing. They, too, have sweethearts, husbands, brothers or sons in the military service, and frequently receive phone patch calls from them. These girls take their work very seriously, and even with all the thousands of phone patch calls they handle, each call has some feeling of excitement attached to it.

Most phone patch traffic from Vietnam is received on the west coast at MARS stations from San Diego, California, to Ft. Lewis, Washington. In southern California, there are more than twelve MARS stations located on Army, Air Force, and Navy installations. Many thousands of phone patches are completed each month through these stations, with additional calls being handled through radio amateurs, members of the Military Affiliate Radio System. One of the busy MARS stations in the Long Beach, Los Angeles area is K6WAH/AA6WAH at Fort McArthur, with radio operators on duty twenty-four hours a day. This station completes an average of 4000 phone patches a month.

It was not my purpose to glamorize the long distance operators, but to commend them for the fine work they are doing to keep up the morale of our servicemen.

Confessions of n Surplus Hound

Some hams are builders and prefer to experiment, some do otherwise. This article is dedicated to the first group. Before the war, I got started in the ham game . . . scrounged and swapped for parts and made do with whatever was available. Slightly used Weston meters at $3 each, secondhand midget tuning condensers at 50¢ . . . that sort of stuff.

Came the war and the subsequent flood of surplus equipment, some good and some not so good, but all of it very cheap. Incredible bargains! An awful lot of that stuff found its way into my basement. I had accumulated so much junk that prior to moving to the new location several years ago, I started six months early to swap, sell and give away all the gear that couldn't be carted to the new QTH. Resolved never to let it happen again! But it did. Maybe that's because I'm hooked on surplus . . . at any rate, here are a few useful tips.

As I said, there is some very good stuff on the surplus market and some not so good. If you should buy a damaged night-light control and fool around and fix the thing, that's all right. Even though you may never use it, you've learned something. But never buy a piece of gear just because it looks nice. Otherwise you will end up with a shack full of surplus and no room in which to put your operating equipment. Don't laugh, please. This has happened to stronger men than you!

Where to purchase the surplus? When Cortlandt Street – New York's oldtime "Radio Row" – was in existence, it was quite simple for thousands of bargain-minded hams to snoop and shop, to visually inspect the gear that was for sale. Today Radio Row is but a fond memory but this illustration points up rule number one: See before you by. This might be impossible in certain cases, so we go on to rule number two: If your buddy bought an item from a particular surplus merchant and was happy with the deal, the chances are good that you can buy the same or similar gear from the same outlet with satisfaction. I can now hear you asking "What happens if I can't apply rule number one or rule number two?"

DOUBLE YOUR RANGE!

Four times the POWER equals twice the range –

Tell Our Advertisers
You Saw It In 73
(Even if you didn't)

You could take pot luck and perhaps end up unhappy. But there are a few angles whereby you can tip the odds in your favor. No guarantee of success, mind you, but a big improvement in your chances. Take a close look at any surplus hound's catalog file. Along with all the popular mail order catalogs you will find catalogs from some of the larger surplus houses. This is usually a good sign, for it shows that this particular firm thinks enough of its customers to go to the time and trouble to assemble, print and distribute a catalog. What with annual or more frequent updating, this all takes time, money and effort. These firms put out these catalogs because they want you to be a satisfied customer. Also, when you receive a catalog, many of the items are illustrated. This works in your favor, since you will have a fairly good idea of what the gear looks like before you buy it. In a catalog there is room for a description, plus specs such as size, weight, color and so on. Less chance for misunderstanding.

Other merchants operate along slightly different lines. That is, they do not feel justified in making up and issuing a catalog at regular intervals. This is particularly true in some cases where the firm specializes in big-ticket items, fewer in number, such as HF receivers, used oscilloscopes and relatively expensive test equipment. The majority of firms that advertise are ethical, and in case you are disappointed, a letter to the firm in question will usually rectify the situation. The chances of your getting burned are greatly reduced if you will follow these simple rules. Why shouldn't you profit from someone else's mistakes?

I have been well served by many of 73's advertisers, among them Meshna, Fair Radio, Jefftronics and Columbia to mention just a few. In the old days I was forced to buy surplus in order to save money. Now I find that I buy the stuff to save time and trouble, not to mention exasperation, since the nearby radio stores don't always carry the particular parts needed. What's that saying by the French to the effect that "The more things change, the more they become the same?"

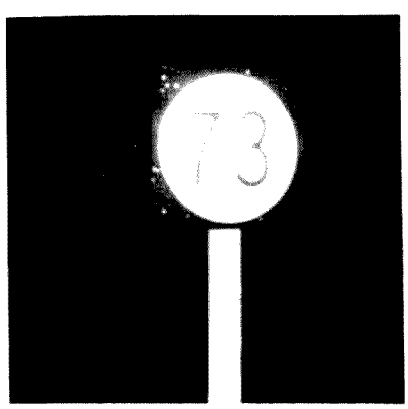
APRIL MCMLXXII Monthly Ha

HAMS AID IN SEARCH

On Saturday, January 22, 1972, St. Louis area amateur radio operators were called to assist in the search for a young man missing from his residence at the St. Louis State School and Hospital. The young man was retarded and partially blind.

Initial efforts to locate the youth were spearheaded by volunteers from the local Youth Association for Retarded Citizens (YARC). After 24 hours of search, YARC leader Tyrone McNary contacted county police seeking walkie-talkie radios. Sargent Joe Owings, Police Radio Supervisor and ham operator, was on duty at the time and immediately contacted members of the St. Louis Repeater Club to request their cooperation. One of the primary functions of the club is to provide emergency communications using VHF equipment owned and maintained by the members.



Lionel Doak KØDCQ and Clarence Herron, Jr., WØKUJ instituted call-up procedures, and within thirty minutes a dozen hams equipped with mobile radios and portable units headed for the search area. Bob Netherton WAØQAH established a radio command post to coordinate the YARC search groups. Other hams with portable transceivers were assigned to specific search parties. The command post was transferred to Sgt. Owings' radio-equipped camper van when he arrived after duty hours. Darkness forced the search to be called off for the night.

Sunday morning additional hams, YARC members, Scouts, and other volunteers gathered at the radio command post to continue the search. Each group of eight to ten walkers included a radio operator. Mobile operators visited area churches and homes to inform the public, with a description of the youth. Many of the YARC volunteers had been working with little rest since Friday afternoon.

Unfortunately the story did not have a happy ending. The body of the youth was found in a creek bed only about ¼ mile from the school grounds. However, the dedication displayed by the young adult YARC group was an inspiration to all. Their volunteer work with retarded citizens usually goes unnoticed. Their involvement and compassion was evident throughout the search and especially when the sad end was known.

In the future, it is recommended that authorities faced with an emergency contact radio amateur volunteer communication specialists just as soon as the requirement for assistance is known. The search was into the second day before the St. Louis Repeater Club members were contacted.

Radio operators who participated include Joe Owings KØAHD, Lionel Doak KØDCQ, Clarence Heeron, Jr., WØKUJ, Robert Netherton WAØQAH, Robert Wingerter KØABA, Robert Familton WAØQOL, William Armstrong WØNC, Randy Wachter WBØCPG, Marianne Familton WAØQOM Forrest Murphy WØFEM, Vernon Hayes WØCYF, Neil Widener WA9OTB, Ralph Edmonds WØKUY, John Landsberger KØLUX, Dennis Hutchins WA9RDY, Bill Reichert WA9HHH, Royce Brown WA9UUF, John Carrel WAØITI, Joe Rome KØPJB, and Robert Silvey WB9CDF.

Arnold Krauel WAØGUD, was there when 73 stretched out its wings and claimed the land 11 miles east of Audubon, Iowa. As you walk down the State Road 73's of life, watch out for the next place 73 strikes. Keep your camera ready.

ECARS PREXY

Hal Winston W2DIR on January 15th assumed the position of President of ECARS, the East Coast Amateur Radio Service. 73 Magazine extends its hearty congratulations to Hal and wishes him the best of luck in this position.

JOHN K3BNS NEW CHIEF OF RULES & LEGAL BRANCH, FCC

Reprinted from the X-Mitter, Penn. Wireless Assoc.

John B. Johnston K3BNS, has been appointed Chief, Rules and Legal Branch, Amateur and Citizens Band Division, of the Federal Communications Commission, effective 14 February 1972.

John will be working under Prose Walker W4BW, the head of the amateur and citizens branch of FCC. He replaces Bill Grenfell W4GF, who retired early in 1971.

John was first licensed as KN2HHR, becoming K2HHR and later K8DAI before moving to Levittown as K3BNS. He is a past president of Penn Wireless Association, past president of Frankford Radio Club, and has received numerous awards for his amateur radio activities. He has received the ARRL CD Article award, and has had many articles published in QST, X-MITTER, CQ, and 73. He is a Life Member, ARRL, and ex-Assistant Director. John is active on all HF bands on CW, RTTY, and phone. He places high in Sweepstakes and the DX contests.

News Pages

SYMPOSIUM DISCUSSES FCC RULES

Representatives of New England and Eastern New York repeater groups discussed FCC regulations which they thought would be beneficial for the orderly growth of two meter FM.

The first item to be brought up was the matter of the frequency of control systems. Under the present regulations all control systems must be on 220 MHz or above. This rule has been around since some time in the 30's or 40's and has been a great big pain with little redeeming merit. Suggestions were made that all restrictions be removed regarding control frequencies and that the end result be defined instead of the means of achieving it. The result is effective control of repeaters in this case.

It was proposed that control be permitted from mobile points. Considerable discussion brought out that there seemed to be no reasonable argument against permitting mobile control of repeaters. The negative thinkers came up with a wide array of improbable difficulties which might demand fixed control points. The positive thinkers countered each negative thrust and won the vote of the majority.

The same discussion got started on the subject of monitoring and whether mobile monitoring should be permitted. The heretical question was raised as to whether monitoring was in all cases absolutely essential and the majority was again persuaded that under certain conditions such as coded access to the repeater no monitoring should be required. Completely open repeaters should be monitored.

The group agreed that unattended repeater operation be proposed to the FCC.

The matter of control of a repeater brought forth a good deal of opinion and some heat, finally being resolved after much compromise with the recommendation that primary control of repeaters be on 220 MHz or above or by means of telephone wires or some other such hard wire control. Primary control was defined as the ability to turn the system on and off. Secondary control or emergency control was defined as the ability to shut the system off or change its functions.

The group also voted to support the petition that has been under consideration by the FCC for some years now for extending Technician operation to the entire 144–148 MHz band.

The group voted a preference for 40 kHz spacing between channels on the 220 MHz band instead of the rumored RACES desired standard of 30 kHz. The wider spacing would be in keeping with equipment expected to be available soon to amateurs and would permit the eventual splitting of channels down to 20 kHz without undue adjacent channel interference. The 30 kHz standard now in use on 146 MHz has caused great grief when split further to 15 kHz and this disaster might avoid repetition if RACES would go along with the repeater groups and agree to 40 kHz spacing. Equipment can be made for 15 kHz spacing, but it would be expensive . . . very expensive.

DYCOMM DEMAND

A letter from attorneys representing Dynamic Communications demands that 73 publish a retraction as follows:

> The models advertised on page 106 of the February edition were incorrect, that they were both discontinued as of January 5th, 1972, and that new models and new prices were in effect from that day forward.

We do try hard to see that only ads that are wanted are run. In the case of Dycomm a proof of the ad was sent with the following statement: "Here is a rough proof of your ad for the February issue of 73. There will be time for us to send further proofs and get your okay on any changes or corrections if we receive your material by December 10th. We cannot guarantee proofs subject to corrections on material received between December 10th and 20th. Contract advertisers do not require an insertion order. As per contract agreement, below shown proof will appear in the February issue. Absolute ad deadline for negatives, changes and corrections is December 20th."

Though this proof was sent to Dycomm on December 5th, no word of any kind was received from them before the issue went to press. The next letter received was from their attorneys demanding a retraction. Had 73 received any communication whatever from Dycomm, by phone, letter, telegram, etc., the ad would have been cancelled. No word was in fact received.

NEWS FLASH

Reprinted from the February *Ham Rag*

As we go to press, Ham Rag's nosy reporters have smelled out a scandal at ARRL Headquarters. Seems that ARRL President Robt. W. Denniston WØDX, has been out beating the bushes in opposition to ARRL's proposal for phone band expansion, so the League has fired WØDX and replaced him with Harry J. Dannals W2TUK, Director from the Hudson Division, as Prexy.

CLUB 18 YEARS OLD

RSBG RadCom – The Radio Amateur Invalid and Bedfast Club, now has close to 400 members in 13 countries and will celebrate its 18th anniversary next year. It extends a welcome to licensed amateurs and SWL's anywhere who are handicapped in any way. Membership is free and the club's newsletter, *RADIAL*, is sent monthly for a small sum to help cover printing and mailing costs.

Inquiries should be addressed to the honorary secretary, Mrs. Frances Woolley G3LWY, Woodclose, Penselwood, Wincanton, Somerset, England.

ACTION AUCTION

With a title like the "Action Auction," the Montgomery ARC must be planning a big turnout. The auction will be held at the Civic Center in Gaithersburg on Sunday, May 14. Bring your gear from 10 to 12, and the auction will begin at noon. Talk-in on 94.

HAVASU HIGH SCHOOL HAMS

Left to right: Randy Strange; Gary Keller; Tom Clark; Howie DiBlasi, Instructor, of WA7RTM, the Lake Havasu High School Amateur Radio Club. The club recently handled 200 messages for students and faculty to all parts of the world. Traffic was passed to 25 states and many foreign countries.

ADDITIONS TO TECHNICAL AID GROUP

(see March '72 *73*)

Joseph Botwinick WA2UVD 137–45 231 St., Laurelton NY 11413. Project coordinator. Joe can lend a hand with AM, antennas, Novice problems, converters, test equipment, surplus and other general help.

Jim Venable K4YZE, 119 Jancey Dr., Marietta GA 30060. Jim is well qualified to lend assistance in VHF-UHF design of transmitters and receivers and antennas as well as being adept with test equipment and solid state matters.

QSL MANAGER OF THE MONTH

Scott's QSL service and DX Assn. is proud to announce the recipients of the QSL Manager of the Month golden microphone trophy. Each month since September 1970 one of the following managers was awarded the trophy for outstanding service. ZL2AFZ, VE3EUU, W7VRO, WA3HUP, W3HNK, KH6GLU, 1NDXA (K3RLY), W3CTN, WA6AHF (xyl Fern), WA2DWE, WØQGI (WAØ buro), W5QMJ (W5 buro), WB8ABN, W2MZV (Browning DXped mgr), W2GHK (DOTM), WA6MWG, KØZFL (K, WB, WN Ø buro), K4ZCP.

By Philadelphia Hams

TV NET FORMED ON 439 MEGAHERTZ

Paul Rilling WA3HIT

A new net was started on Friday, January 28, 1972 by net control K3ZKO Ron Cohen of Philadelphia. What makes this net unique is that it is a TV net (fast scan). Sponsored by the Mt. Airy VHF Radio Club, Inc. (Pack Rats), the net meets each Friday from 7 to 10 P.M., Philadelphia time. Ron (who is known as "Captain Video") believes that this is the first TV net to be formed in the East, and the first of its kind anywhere in the U.S. The frequency is 439.25 (video *and* audio). Philadelphia hams call this frequency "Channel 13¾." If you cannot copy K3ZKO-TV, look for WA3AXV-TV, whose handle is also Ron. K3ZKO will run test with those stations who wish, as well as listening on 146.58 MHz (2 meter FM ATV engineering channel) for those who can only receive but want to take part. Both Ron K3ZKO and Paul WA3HIT have color receivers for those who want to run tests while transmitting in color. Anyone can receive this net on a conventional TV set with a modified UHF converter (frequency adjusted 30 MHz at low end). Ron K3ZKO expects about twenty ATV stations from New Brunswick, N.J. to Westville, N.J. to be regular check-ins each week, and many more stations on 146.58 FM, who are monitoring only.

NJ AMATEUR OF THE YEAR

On January 21st, Anthony Butterhof K2JOX, was presented with a plaque and cash award in recognition of his many years of service to the southern New Jersey area hams. His dedication to ham radio has been demonstrated many times over the years.

He has served as president and member of the Board of Directors of the Southern Counties Amateur Radio Association, has served onany committees, participated in many SCARA activities and programs. In 1971 he organized several transmitter hunts, promoted club activities, was prime mover during Field Day, technical advisor in the installation and operation of the club repeater, and served as chairman of a special committee that established WX2MAP, the special events station that operated in conjunction with the Miss America Pageant. Anthony acted as coordinator between the Pageant officials and the amateur club. He provided for acquisition of material and installation of the antenna and radio equipment for this station, participated in the operation of this station, and coordinated the QSL card efforts for the event.

Currently he is the committee chairman of the Kiwanis International special events amateur radio station, due to become operational this year. He has organized code and theory classes for prospective Novices at the local high school. And he has held many positions in local and county Civil Defense organizations.

The award is presented each year by Atlantic City radio station WFPG to the outstanding amateur in the southern New Jersey section.

NEWS FROM AROUND THE WORLD

According to a newsletter of the Canadian Amateur Radio Federation, the age limit for the Amateur Experimental Service has been dropped, the eleven meter band is to be turned over to the exclusive use of the General Radio Service, and the Ministry of Communication is considering the lowering of qualifications necessary for amateur radio operators and creation of a new class of junior license restricted to operation in a UHF band and an output of three watts. This last item is particularly interesting as the CARF feeling is that any matter about amateur radio should have the approval of all licensed amateurs. Until all facts are known, however, concerned persons should not condemn the Ministry. There is the possibility that this Restricted Amateur license will promote the development of 450 MHz equipment. This will be a worthwhile event to follow.

METRO SNO-DO 100

By Al Molden VE3CLE

Reprinted from the Toronto FM Society Bulletin

After a delay of one week, Metro's first recorded snowmobilathon took place February 5.

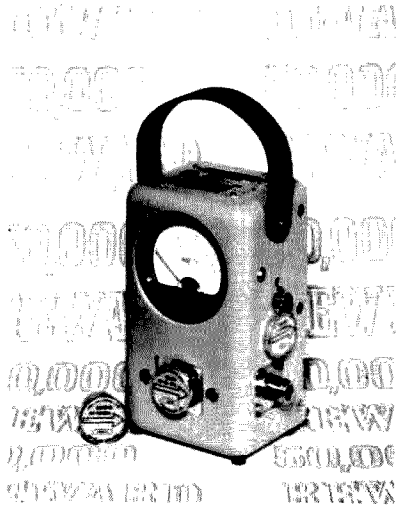
Presented by several Metro area Civitan clubs, the Sno-Do took place over a hundred-mile course. Similar to a walkathon, but run on snowmobiles, it offered snowmobile owners a fund raising, fun-type endurance test for their machines. It was not a contest, but each entrant was asked to obtain sponsors who paid for each mile completed. All monies were equally divided between the participating clubs, whose common objective is to fight mental illness and help mentally retarded citizens.

Point-to-point communications on the rally was organized and carried out by the Toronto FM Society. They filled in the snowmobile/mobile end where a lack of ham manpower was evident. Four FM mobiles, those of Stan VE3AZD, Dan VE3CIQ, Barry VE3FBH, and Ray VE3GSK, were positioned at strategic points along the course, and track was kept of the position of each snowmobile as the day progressed. The base station was supplied by Chuck VE3KQ and ably manned by Al VE3CLE.

It was a good day for hams and snowmobilers alike. Without ham help, the event could not have been as successful as it was - other clubs are encouraged to lend support whenever and wherever reliable communications are needed.

HOT GEAR

On Feb. 3, 1972, YAESU Model FT-101 Transceiver, S/N 107036, equipped with CW filter, was stolen from the automobile of WA2YSW while it was parked in the driveway of his home. Contact Frank W. Widmann, 328 Farwood Road, Haddonfield, N.J. 08033, or Officer Latham, Police Headquarters, Borough of Haddonfield, 242 Kings Highway East, Haddonfield, N.J. 08033.



A 2 meter FM Standard Transmitter SRC 806M, Serial Number 102703, was stolen from the car of Clem Mathias W6NPV on January 25, 1972. Contact him at 3134 Coronado Ave., Imperial Beach CA 92032.

In Elmira, N.Y., Glen WB2LRR reports a Drake ML2, Model No. 20189 100N PL, stolen.

BIRD OFFERS REWARD

Bird Electronic Corporation offers a reward to twenty owners or users of a model 43 THRULINE RF Directional Wattmeter. Designed under the direction of the late microwave pioneer J. R. Bird when the industry was in its infancy, production of the famous "43" has just passed the 50,000 mark. This portable insertion wattmeter measures from 1 to 10,000 watts from 0.45 to 2300 MHz in discrete bands determined by the plug-in element used.

In celebration of the 50,000th unit, Bird will give away 20 standard plug-in elements to serial numbers taken at random on 10/10/72. Users selected will choose their element according to desired frequency range and full-scale power level. Mail the serial number of your model 43 on a card to *Bird Electronic Corporation, 30303 Aurora Road, Cleveland (Solon), Ohio 44139.*

THE 50 MHz BAND

by WAØABI

The December openings started off with a bang early in the month, giving rise to hopes of another period similar to 1967 but after openings the morning and evening of the third and the evening of the fourth things calmed down. While there were multiple openings, they were of short duration and rather spotty. WA2ENZ and WB2BLL joined in a ragchew with KØRIR, WØRVF and WAØABI on the 20th while on the following day VE1's were heard but were too far down in the noise to work.

Word has it that the 1972 meeting of the Midwest VHF Society will be held in Kansas City, but no date has been set as of this writing. Hopefully a date will be announced shortly so those who must schedule their vacations well in advance will be able to make the necessary arrangements. Several people from this area were forced to miss the 1971 meeting in Sioux Falls due to inability to arrange time off from work. A Kansas City trip is in the planning stage; hope to see you there.

There is good news for those in need of a Kentucky confirmation.Ted WB4VLH, is newly active from Paducah with a Clegg Venus and a pair of 4X150's. Ted joins Dave WB4YIH, who has been on for some time from Owensboro as K9DZK/4. These are the only Kentucky stations ever heard from this midwest location. W5SXJ was heard aeronautical mobile on both legs of a business trip through the St. Louis area. Ray seemed to be having a ball making contacts at the drop of a hat and at times rag chewing over a four state area.

Mike WØZYS, is QRX while the tower is being moved to a new QTH and should be back on the air shortly.

Several Heath SB-110's around have developed a habit of jumping from 1 to 1½ kHz, in each the problem started abruptly and after the rig was several years old. In each case the problem was found to be in the heterodyne oscillator circuit. Should you have this problem, blow about $2 and replace all the resistors and capacitors in these circuits at one time. This may seem wasteful and you may never know which component was defective but it is far better than removing the shielding and bandswitch to replace components one at a time.

Your assistance in supplying current, factual reports of activity are needed to keep the column interesting and useful. I would also like to receive your comments as to what you would like to see in this space. Unless you speak up, you'll have to put up with my findings.

HAM TUNES IN TO BURROWING BURGLARS

by Henry Maule
Reprinted from the Knoxville (TN) Journal

Robert Rowlands is a prosperous 33-year-old company director who maintains an elegant apartment in London's West End. Like many a hard-working businessman, Rowlands relieves the pressure with a hobby. He's a radio ham.

At 11 o'clock one seemingly quiet Saturday evening not long ago, Rowlands turned on his high-powered equipment and began reaching into the ether for another ham, preferably someone far off. Perhaps he might even wind up chatting with none other than Jordan's King Hussein, who escapes from the woes of the troubled Middle East by doing a little radio hamming himself.

As luck would have it, Rowlands' short-wave receiver was tuned in on 27.5 megacycles. This was precisely the frequency of a set of walkie-talkie radios being employed, at that very moment, by an enterprising gang of bank robbers who had tunneled their way into Lloyds Bank branch on nearby Baker Street.

The bank is situated only a block from 221B Baker Street, the address of Arthur Conan Doyle's famous fictional detective, Sherlock Holmes. Ironically, although their equipment was ultra modern, the thieves were employing the same technique of the robbers in Doyle's story, "The Red-Headed League."

The non-fiction gang tunneled 15 feet downward from a vacant store two doors from the bank. Then, with picks and shovels, they dug their way 40 feet horizontally under a restaurant called "Chicken Inn" to the bank itself. Next, they dragged in gas cylinders and a thermic lance to attack the four-feet-thick reinforced concrete floor of the strongroom. A thermic lance is a specialized cutter used industrially to cut through concrete.

The diggers had walkie-talkies and so did a lookout planted, with binoculars, on a nearby luxury house rooftop. It was on a little tete-a-tete between the gent on the roof and the burrowers that Rowlands beamed in with his sensitive receiver. It was the night of this past Sept. 11.

It took a little time for Rowlands to catch on. The first thing he heard was the exultant cry, in a decidedly Cockney accent: "We've got at least 200 grand!" The robbers had reached the vault.

Like a dutiful citizen, he telephoned the nearby police station in Marylebone Lane. His immediate impression of the reaction at the other end was that they believed him to be a hoaxer or a crank, but he eventually persuaded them to send an officer around to his home to hear for himself.

Rowlands urged that a General Post Office detector van should be called in at once to pinpoint the source of the robbers' conversations. The constable assured him this would be done immediately.

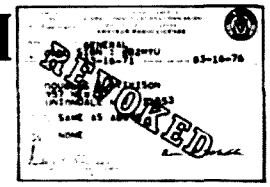
The gang's crosstalk made reference to drilling in the street, and there was also talk of a waiter in a nearby restaurant who kept peering through a window.

Rowlands felt these were two valuable clues which would help the police pinpoint the actual bank in which the raiders were so diligently at work. But the police did not seem to appreciate the importance of conversations the radio ham was taping.

Furious at their lack of concern, Rowlands phoned Scotland Yard, told them what he had heard over the radio, and said it was quite clear a robbery was in progress involving a lot of money and valuables.

Even though the Yard's reaction did indicate more interest than had been shown at Rowlands' local police station, their approach to the bank robbery was pedestrian in the extreme.

Two days later, on a Monday, the completed robbery was discovered at the Baker Street Branch of Lloyds Bank. In the angry official inquiry that followed, the big question was: What about the Post Office detector van that Rowlands had suggested?



The Post Office people insisted that the robbers stopped transmitting five minutes after the detecting equipment was brought into play.

"If we had been alerted sooner," said a spokesman, "we could have found the transmitter very quickly. Once in the area, we could have pinpointed the building in a matter of minutes."

The police reported that they had put in a call for the use of the detector van 10 hours earlier, but had been told it was not possible to contact the unit because it was not on 24 hour duty. To which the Post Office replied that the police had not indicated there was any particular urgency. It did nothing to reasssure the owners of the robbed deposit boxes when Scotland Yard later issued a statement that they and the Post Office were tightening their emergency links. "We have established where the weaknesses were," said a spokesman. "We have learned lessons from this episode and it won't happen again."

As a certain onetime resident of Baker Street would undoubtedly have commented, were he around: "What can one expect? It's elementary, my dear Watson."

WITH THE FCC

Following is a reprint of an article in the Texas VHF-FM Society NEWS in which a summary of Prose Walker's comments at SAROC appeared. In the relaxed atmosphere of his visit, he was able to comment more explicitly on several issues of prime interest to hams. This article represents a superb review of current FCC thinking. It must be remembered that Mr. Walker stated his ideas in places, and that unless indicated, these items have not been placed into effect.

FCC AMATEUR CHIEF VISITS NORTH TEXAS

A. Prose Walker, W4BW, Chief of the Amateur and Citizen's Division of the FCC was a guest and featured speaker at the January 10th meeting of the Richardson Wireless Klub. Throughout his visit, Mr. Walker was constantly bombarded with questions about the probable outcome of the various rulemaking actions pending before the FCC. Mr. Walker was free and open with his answers, and lent considerable assurance that we are, indeed, represented by a ham's ham. He did preface his remarks with a caution that they be interpreted correctly and kept in context. That context is worth explanation.

As Chief of the Amateur and Citizen's Division, Mr. Walker directs and administers the preparation of the report and order which is the culmination of any rulemaking procedure. However (and this must be understood clearly), the initial report and order prepared by his division is not necessarily ever issued as it was written. After his division's work, the document must be analyzed by the FCC legal staff, by the Safety and Special Services Bureau, and finally by

the seven commissioners. There are many opportunities for reversals in this approval path, and the final report and order may be substantially different when issued than when drafted. Mr. Walker's beliefs and findings, then, can be assumed to have a direct influence on the work done in his division, but cannot be assumed to carry promise about the final rules.

Mr. Walker thinks the report and order following docket 18803 (VHF Repeaters) might be issued before mid-year. It will probably be issued first, before the phone band expansion, "eye bank," and 220 MHz hobby band subjects are finished. In summary, it seems that VHF repeaters will be dealt with kindly and almost completely in accordance with our Society's comments. The extensive linking of repeaters for non-emergency use might not be permitted beyond a total of two, or at the most, three machines.

Mr. Walker believes that sub-band allocations as proposed by the FCC are not necessary beyond prescribing what portion of each band may be used for repeaters. He delivered an admonition that we hams coordinate immediately, effectively, and nationally to formulate a frequency coordination plan to obviate interference between repeaters and stations of other types, and among repeaters themselves. Such coordination would have to take into account the newly established amateur satellite service and other users of the spectrum. While not suggested by Mr. Walker, this subject seems to be of sufficient importance that it might well become a crusade within the ARRL.

The information required on license applications for repeaters may change to include those items directly related to establishing a service radius. Such items as height above average terrain, power output of the transmitter, transmission line loss, and horizontal and vertical pattern data may well be required on future applications. Conversely, the requirement to explain in detail the functioning of every relay and other system component probably will be eliminated.

Access by tone may be required, if for no other reason than to establish without doubt the using operator's intent to key a repeater. This possible requirement ties directly to the subject of unattended operation. The commission has apparently, regardless of Mr. Walker's disposition on the subject, not yet reached a decision about whether the prime responsibility for repeater operation lies with the trustee of the repeater or the licensee of the station using the repeater. Carrier-operated repeaters appear to be likely to be prohibited unless they are monitored and controlled full time. Tone-access repeaters, however, seem to be better candidates for unattended operation – although the subject is by no means resolved at this time.

Logging of transmissions will probably go, automatic identification of repeaters will stay (and in fact, a future requirement is being studied for fully automatic digital identification of all transmitters), in-band control probably will be allowed, and a technical log might be required. Rather than list each of the points made by each of the comments submitted to the commission, Mr. Walker indicated that we probably would be permitted each of the boons we sought – with the possible exception of unattended operation. He personally believes as we do that unattended operation should be allowed and readily cites the precedent established by the land mobile services in support of his beliefs. His ability to convince the commission, however, will be the determining influence in the outcome. Considering Mr. Walker's knowledge, experience, level of concern, and understanding of what ham radio is all about, coupled with his apparent deep interest in repeaters, it is difficult to be anything but optimistic at this point.

Mr. Walker touched on several other subjects outside the area of VHF repeaters. Some of the more significant items are reported here. There probably will be an expansion of the 75 and 40 meter phone bands. More space might be provided on 160 meters. Ten meters might support a small allocation for repeaters. The EIA petition for reallocation of part of the 220 MHz band for citizen's band operation hasn't been resolved. There is much pressure for its adoption, but there are serious potential problems in the areas of enforcement and the federal government's priority in the band for radio location services. Because the issue is so "up in the air" at the moment, Mr. Walker suggested that amateurs do nothing until or unless the FCC issues a notice of proposed rulemaking.

The commission is concerned about amateurs who run more than the legal kilowatt. It seemed that the FCC has just about run out of patience with the problem and is prepared to legislate a cure. One solution might limit the plate dissipation rating of vacuum tubes to a certain level. The best solution is to clean up our own ranks of the violators and scofflaws. The message was very clear. Another subject discussed in the same unpleasant vein was the apparent large number of frauds holding conditional and technician licenses. In six months of 1971, 134 licensees of various classes were called in for re-examination. 59% failed to show, 17% failed the test, 24% passed. Suspected perjury concerning qualifications prior to renewal time has attracted the commission's attention, and steps are being taken to reduce the number of violations.

The entire subject of call signs will shortly receive commission attention. The block of prefixes AA through AL have been assigned to the U.S. but have not been assigned in the amateur service as yet. Many possibilities exist, and the final outcome may be a long way off, but some examples of what might be done are: Extra class licensees might receive prefixes W/K/WA/WB, etc., with a one or two letter suffix. Advanced class might use part of the AA-AL block. Generals might get nothing but "1 X 3" calls. Novices "2 X 3" with WN or KN prefixes, and repeaters the same with WR or KR prefixes. The idea supports two considerations: the most obvious is the benefit to the monitoring service in determining the class of licensee; and a secondary benefit is the incentive attached to receiving a prestige call in the higher class license grades.

Two new grades of technician class licenses may be established in the future to replace the current technician class. They would be no-code licenses, but with two grades of technical competence indicated by names like "VHF general," or "VHF extra," just to cite an example. Repeater trustees would likely be of the higher grade only. Mr. Walker's discussion on this subject received enthusiastic support from his audience.

Mr. Walker's final point concerned the possibility of establishing more HF ham bands. Many countries are ceasing operation of their HF fixed stations in favor of cables and satellites which provide much higher reliability. The spectrum vacated by these services could be made available, in Mr. Walker's opinion, if we hams begin to work now at a professional and diplomatic level. The next World Administrative Radio Conference in 1977 will treat HF spectrum allocations, and it behooves us, he thinks, to get busy right away within the League making preparations. It is a serious and difficult subject which encompasses not only domestic but international effort of the highest professional quality, but it is not impossible. Mr. Walker tantalized the audience with visions of ham bands every 2 or 3 MHz throughout the entire HF spectrum!

PLEASE INCLUDE YOUR ZIP CODE WHEN YOU WRITE 73.

FCC REPORT

by Bill Grenfell W4GF

Reprinted from January 1971 Auto-Call. Re-reprinted from February, 1972 Ra Ra Rag.

The ARRL response to the Commission's Docket 19245 Notice of Inquiry has been filed and is, I think, quite revealing of an attitude which, unfortunately, does little to help the FCC resolve the problem.

Briefly, this concerns Section 97.39 of the rules which say amateur station licenses "will not be issued to a school, company, corporation, or other (non-amateur) organization, nor for its use . . . " Although it has been advising others of its belief that the rule prohibited amateurs from furnishing communications on behalf of non-amateur organizations for more than 14 years, the FCC's reply to a Lion's Club letter that the rule applied to the Eye Bank Net (which is sponsored by the Lions' organization) caused a big fuss and resulted in the writing of some rather heated and misleading editorials. See November 1971 QST, page 79 for the filing, my June 1971 Auto-Call report (page 5) and October 1970 QST editorial (page 9).

While Bob Booth's work in preparing the comments for ARRL is quite comprehensive and well documented, I believe it strays from the most productive direction and that some of the arguments presented weaken, rather than strengthen, the League's presentation. For example, the comment traces the controversial "nor for its use" phrase back to the amendment of the rule made by the FCC in 1938 as a result of the League's request "to close the loophole." It states that "the League most certainly would not have suggested the addition of the phrase "nor for their use" and "nor for its use" if there had been even the slightest indication that the phrase might even remotely be interpreted to restrict the message handling activities upon which the League has been built since 1914." League Secretary Warner's December 1928 QST editorial discussing the "nor for its use" phrase is cited. What the League's comment fails to recognize and deal with is that *the phrase has been interpreted to apply to communications* and therefore, if this is undesirable, the *only* way to prevent such an interpretation in the future is to change the rule. It should be recognized that early rule language and interpretations cannot remain unchanged when the communications and the people involved in station operation and in the regulatory process change as time marches on!

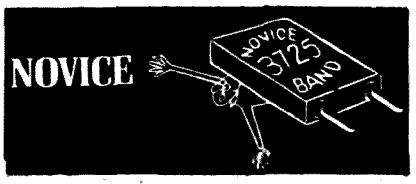
From my point of view as a former FCC employee of 20 years involved in this amateur regulatory process, I think I can reflect the Commission staff's point of view in observing that the reference to the Commission's "persisting in its misinterpretation of Section 97.39" is hardly going to win them over. I think the views of a majority of the Commissioners themselves is probably well represented by Chairman Burch's statement to the Washington Chapter of the QCWA last March. I recommend that you read it. (QST, May 1971, page 81)

The Commission and staff has given the amateurs and their League every opportunity to participate in arriving at an agreeable solution. I hope the League will see its way to forget the past and provide positive help to the Commission.

Gf

FROM THE FILES OF THE FCC

Finds 'em, Catches 'em, Cancels 'em!



A U.S. District Court Jury found two Des Moines men guilty of violating FCC Rules governing the use of CB radios. Raymond W. Huxford, 55, was convicted of exceeding FCC limits on CB radio antenna height, power output, length of broadcast and of violating FCC Rules by operating on unauthorized frequencies, using an unauthorized call sign, relaying messages for persons other than himself or family, and sending messages as a hobby or diversion. Mr. Huxford was found guilty on six counts of violations of the Communications Act.

James O. Edmunds, 40, was convicted of exceeding FCC limits of length of broadcast, operating on unauthorized frequencies, using an unauthorized call sign and sending messages as a hobby or diversion. Mr. Edmunds was found guilty on four counts of violation of the Communications Act.

U.S. District Court Judge William Stuart continued bond at $2500 on each defendant and delayed sentencing pending pre-sentence investigation.

Refer to 73, December 1971, for more details.

The General Class license of W9LMR is under suspension for out of band operation. He was monitored while operating on 7004.6 kHz and was so notified of the violation. FCC rules require written replies to such notices. LMR did not reply to the first nor subsequent letters and hence the suspension. In other action, the Extra Class license of WB4DXX is under suspension for the remainder of its term for several violations. The first was communicating without identifying his station at proper intervals, and for transmitting signals for a purpose other than communication. Official notices of violation were sent on two occasions for these and no reply was made. On another date, the transmitter of the licensee was transmitting in "excess of its modulation capabilities for proper technical operation, resulting in excessive distortion and frequency instability." A notice was sent to WB4DXX and he replied explaining the circumstances. A third violation was committed on another date when he willfully interfered with other signals. The response to this notice claimed the interference was willful but not malicious, and the interference was due to negligence on his own part. In the FCC order, the findings are summarized in the statement, "That the licensee's actions described above are contrary to the public interest, convenience and necessity standard of Sections 301 and 307(a) of the Communications Act of 1934 . . . " It was ordered that the Extra Class license of WB4DXX be suspended for the remainder of the license term.

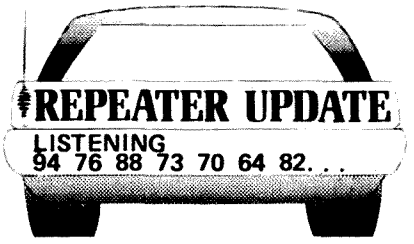
There is such a variety of equipment available kit form and ready made *and* homebrew too that setting it up for total enjoyment should be emphasized. Your station has to be efficient and comfortable too. Some Novices (and higher class licenses) prefer to install their stations in cabinets or platforms that are above the operating desks. This looks well and it leaves the table top clear for logbooks, pencils, keys, and mikes. All the additional space under the rig can be used for storage and also for extra room if your operating desk is also used for a work bench. This presents a neat and orderly appearance that is impressive to visitors and also convenient to operate if controls do not have to be adjusted often.

Another arrangement is to tilt the front of your equipment so that it seems to face you as you look down at it. This eliminates the squinting and hunching down to read dials and meters. What's more, it looks like the gear is mounted on a professional work bench. Perhaps a short SWR bridge can be placed underneath to act as a support. This adds a nice touch as this otherwise empty space is filled with another knob or two and a meter.

(continued)

But is your desk set up for maximum operating convenience? Can you sit at the table comfortably for several hours and not get tired from eye strain, arm muscle fatigue, writer's cramp, or other afflictions of the ham? The first arrangement described above looks fine and as mentioned, as long as you do not frequently retune the transmitter or receiver, it is easy to use. Certainly there is adequate space to stretch your entire forearm on the table to make sending with a hand key easier, and there is sufficient room to work with scratch pad and log books. But can you sit there for a few hours staring straight ahead at eye level, staring at the dials? I would imagine that your back would hurt from sitting erect so long and alternating with leaning over while sending. And if you have to retune the receiver or transmitter frequently, as in a contest, your arm will have to be raised to turn the knobs and your shoulder will ache. If the rig is at a certain height, your elbow will bear the weight of the arm that it supports. Lowering the rig might help to relieve some of the physical pressures of operating over extended periods.

Raising the rig has its attendant problems too. If it is too high, the forearm will be supported by the muscles in the upper arm and a lot of weight will be balanced at the elbow. Your arm is like a lever and if the load (the hand and forearm) is long and the opposite side of the lever is short (your upper arm is almost vertical as you sit at the table), muscles in the arm and shoulder will soon ache and the elbow hurts. Lowering the rig to a point where the forearm can rest on the operating desk and knobs can be turned with a thumb or a couple of fingers will help a lot in easier operation. This arrangement also offers the advantage of having the gear next to your hand as your arm and hand are relaxed.



Are you right or left- handed? Do you tune your receiver often? Is the main tuning knob close to the hand that can more comfortably turn the knob? Some receivers have the tuning knob close to the left side of the receiver and if you are right handed, you will have to reach across your body to operate it. By reaching across your chest, you constrict your chest and breathing becomes a little more difficult. It may not be too noticeable at first, but after an hour or two, you begin to feel a little fatigued from cramping your lungs and breathing muscles. If the desk is not too wide, put the less frequently used equipment above but not so close that rising heat causes problems with stability.

Loudspeaker and headphones should be within easy range, the speaker such that it does not send sound to only one ear, and the cans in a position that they can be quickly reached and plugged in. Paper, log, pencil all have their place too. Lighting should be not too strong or weak and preferably it should be indirect, that is, reflected off a wall or ceiling. Avoid glare.

Ham radio is an enjoyable hobby so do not make it physically hard to enjoy it. Station arrangement for convenience and comfort is an art. Think of how much each piece of gear will be used in comparison to each other piece. Are frequently used items handy or buried in a drawer? Taking the time to set up everything for comfort helps to enjoy the art of communication.

And do not place your station in front of a drafty window.

Navy MARS repeaters are linking on a coast-to-coast network. The latest information is that they are using input and output frequencies of 148.41–150.09; AF MARS uses 142.155–143.46; and Army MARS uses 143.35–148.01.

Tnx to KØLAV, W1HQV, K9DZE, K1KRY, K3ZQN, K4ZZO, W9BLR, W1GAN, W2EXQ.

When you hear a new repeater on the air, drop us a line and we'll share the news. If you hear of one going off the air, let us know also, please.

National 52 Simplex

The move toward using 52 as a national simplex frequency got support from the repeater groups of the Northeastern U.S. at the meeting of 75 repeater groups in Westchester (PA) and about 50 groups in Shrewsbury (MA) early this year. All agreed to the 52 transceive channel. Add this to the similar agreements in the midwest and you have a movement.

With the hope of encouraging this idea 73 wrote to the manufacturers of FM transceivers and asked that they consider including 52 pairs in their sets in the future instead of 94 pairs. Several manufacturers were enthusiastic about this and as present stocks of the 94 crystals get down to reasonable levels the new 52 pairs should start getting into service. Many manufacturers indicated that their customers have only to write to them and an exchange of crystals can be made at no charge.

To encourage the move to 52 simplex 73 will publish a box score for the next few months listing all sets which will be coming out with the 52 pair.

Why the big push for 52? This should take some of the pressure off the use of 94 as a simplex frequency. The 94 pairs of crystals in sets has resulted in heavy simplex use of this channel in the larger urban areas and this causes trouble with 34–94 repeaters. All you need to do in the New York area is hint at a new 34–94 machine and 94 will turn blue as the emotions pour out, obscuring reason from 88 up to 97 or so.

The fact remains that there are more 34–94 repeaters than any other and they are not going to be wished away by New York or Los Angeles or the other big urban areas.

With the cooperation of crystal companies and transceiver manufacturers the change to 52 can be made during the next few months. Inexpensive crystal pairs for 52 will help. Free exchange of crystals by manufacturers will help. Cooperation will help most of all. Does it really make sense to sound off endlessly about getting repeaters off 94? The view from Jackson Heights (NY) may tell you that just about everyone in the world is using 94 as a transceive frequency and everything would be just great if those crumbs over in New Jersey would just move that repeater in Greenbrook. A look at the repeater list in this issue will tell you the big story of the multiplicity of 34–94 repeaters around the country and the virtual impossibility of getting "all repeaters off 94." Perhaps 52 is the better bet.

Derrick Electronics in Broken Arrow OK will supply crystals for all the commonly available rigs for only $7.75 *per pair*. Converted commercial rigs are slightly more. Derrick is the first supplier to indicate this type of support for a national simplex frequency. Sonar Radio will supply any crystals to the users of their products as substitutes for 34–94 and 94–94.

EDITORIAL BY WAYNE GREEN

OUR PROFILE

It should be no news to amateurs that CB groups have been stealing the thunder from us as far as public service is concerned. The communications provided by a group of CBers with mobile units is fine for most local area situations and in most parts of the country CB has been putting amateur radio to shame.

The size and expense of amateur radio equipment for the low bands has been such that interest in mobile operation has dropped tremendously over the last twenty years. In the old amplitude modulation days a little mobile converter and low powered transmitter weren't a big deal. The converter played through the car radio and worked fine. Then came sideband and a whole new ball game as far as stability and complexity was concerned. And out went wholesale mobile operation as we knew it in the early 50's.

Mobile operation is back, stronger than ever, but it is on two meter FM now and works through repeaters. We have better communications than we ever had before, so how about using it for public service? We can now talk base to mobile to hand unit over a range of about fifty miles from most repeaters, ideal coverage for most local applications.

Okay, we have the facility, how do we swing into gear with it? How can we make this pay off for amateur radio?

The number of events and situations which can use good communications is endless . . . it can be almost any sporting event such as boat races, bicycle races, ski races, cross-country races, car hill climbs, car rallies, parades, telethons, etc. All you have to do is keep your ears open and get the member of your repeater group to keep on watch for opportunities to serve.

Providing service is fun . . . a lot of fun. You'll be right in the middle of what's happening and you'll be working with the people who are running the event. You may find yourself parked in an out-of-the-way spot along with a small team of timers on a rally checkpoint. Your job will be to send the times of the cars passing through the checkpoint back to the rallymaster so he can compute the scores. You may well have to do this for two or three different checkpoints through the day if it is a long rally. The chances are that you'll emerge from this job with a strong interest in rallying.

Serving is fine, but please don't forget that the service is only half of the work. You may be self-effacing and not want to blow your own trumpet over what you've done, but amateur radio needs all the credit it can get so put your modesty aside and let the local papers know what you are going to do, what you are doing and what you have done. Also alert the local radio and television stations . . . get good PR for amateur radio. And . . . please . . . send a copy of the newspaper item to 73 when you get done so we can perhaps make a mention of it in our newspages . . . we send reprints of the better newspages to Congress.

HIGH POWER BASE STATIONS

Repeaters are designed to work with mobile stations running on the order of ten watts. Most of them will give coverage of about fifty miles or so under these conditions. So what happens when someone comes along with a home station running 250 watts plus a nice big beam which steps that up to about the same signal a 5000 watt mobile would put out? Chaos.

A big base station can lift repeaters for a couple of hundred miles around and put several out of business while making a local contact.

If you have a big signal base station please keep in mind that it is within your capability to ruin the fun for a lot of people when you are inconsiderate. Fellows will go along with you on an occasional band opening, particularly if it isn't at the peak operating hours, but don't be in there night after night wiping out repeaters in the next state just because you don't care. Fun is the name of the game . . . fun for as many people as possible. So don't spoil the fun.

PRIORITY INPUTS

One of the grumbles frequently aired by FMers who have come into ham radio via the two-way communications route is that too many base stations take up repeater time and don't let the lower powered mobile stations get a word in. Now and then there is a case where a real emergency comes up and long-winded higher powered ops just won't shut up long enough to let a breaker get through with emergency traffic.

Rather than go the route of freezing base stations out of repeaters, perhaps we might think of the situation in terms of needing more repeaters, not less activity on the ones we have. Until all of the two meter and even the 220 MHz repeater channels are full and active, we do have room for repeater expansion.

Emergencies and low powered mobile entry into repeaters can be solved by setting up a second receiver at the repeater site with a priority hookup so it will override the regular base station input channel. One reader has gone so far as to suggest that a "national" emergency calling channel be set up which would override all repeaters. We could set aside one channel for strictly emergency traffic input and have it take over all repeaters in range, but this would require an awful lot of cooperation on the part of the users to keep the hell off that channel except when the emergency arrives. Perhaps that is too much to ask.

COLLINS KAPUT?

Apparently no decision has yet been made by the Collins management about the future of the amateur radio division. Rumors are, of course persistent that Collins will close down their amateur radio manufacturing.

Collins, once leading the industry with new designs for amateur equipment, seems to have stopped their development about ten years ago at the time of the ARRL petition to the FCC which eventually resulted in the downgrading of most amateur licenses.

This is a far cry from the days when Collins had just brought out the 75A1 and the 32V1 and were busy selling the advantages of sideband to the Air Force. Old-timers will remember the many flights around the world made by Art Collins WØCXX with Mort Kahn W2KR and a handful of other "important" hams made in Air Force planes with Generals Butch Griswald and Curtis LeMay. These chaps talked with their small group of friends on the high end of 20m phone, continuing the "private club" type of ham radio so popular on the high end of 75m during the 30's.

Perhaps this is exaggerated in my mind, but I seem to recall that as part of the effort to sell the Air Force on Collins sideband equipment, their ham gear was installed in just about every-

thing General LeMay had that moved or was around him . . . home, car, plane, boat . . . etc. However the sale was made, it seems to have worked and millions of dollars of Collins gear was bought by the Air Force, or was it billions?

Somehow, though the equipment is the oldest still being marketed for amateurs, Collins equipment still has prestige. It certainly was fine in its day. The cost of redesigning would be very high now and there seems little likelihood that the new Collins management, strapped for cash, would find it worthwhile to make the investment required to continue to sell in the static sideband ham equipment market. FM is the big one in 1972 and in that field Collins would be starting almost from scratch and would be up against those little transistor radio makers from Japan.

What will happen to used Collins prices if the factory closes down the dealer setup? This could have serious effects once parts and repairs are hard to come by.

Being practical about it, there seems little possibility that Collins will continue to make ham equipment. It is sad to see another top name in ham radio go.

* * *

Old-timers do not have any corner on the market when it comes to grumbling about how bad things are in the ham bands. The Nattering Nabobs of Negativism are souring away, badmouthing the inconsiderateness on twenty meters, the lids on six, the base stations who talk at length over repeaters, and so on and on and on.

Perhaps it is the old psychological mechanism known as projection that they are seeing. It is just possible that the reason they are complaining so bitterly is that they are faced with themselves at every turn and don't ever see anyone else. That's enough to turn any stomach.

Is there a pat answer to this? An easy solution?

I think so. The next time you get regaled with sighs and groans about what our bands are coming to, suggest (tactfully) that said griper try finding out a bit about the chaps that he talks with the most. He could make up a set of index cards or a file folder with notes on each regular contact . . . full name, wife's name, names of children, what all of them do, other hobbies of his and his family, places he has visited, what equipment he has and maybe what he is thinking of getting, notes on any interesting yarns he has told, what other ham interests he has, bands he works.

Such a file will serve several purposes. Getting the information will result in some of the most interesting contacts the other fellows have ever had . . . and they will comment on this. People like talking about themselves more than anything else in the world. Your curmudgeon will soon find that, once he knows more about the chaps he has been talking with, he will enjoy the contacts a lot more. They will be with people, not just call letters.

Can this system fail? Probably, but you'll have to prove it to me by trying it first.

73 TOUR OF EUROPE IN SEPTEMBER

How would you like to walk around Moscow with a transceiver and work a bunch of amateurs over there with you on a tour? Special permission has been requested to permit U.S. amateurs to visit Moscow this fall and bring along their two meter transceivers . . . plus permission for 73 to bring along a complete small repeater unit and set it up so we can all keep in touch from anywhere in town. Will that be fun?

The trip is scheduled to start September 4th from New York and fly first to Copenhagen . . . Tivoli amusement park will be open . . . some of the finest restaurants in the world . . . and REAL Danish pastry . . . or would you rather take a look at those sex shops? We'll arrange for you to meet Danish amateurs and visit with them . . . perhaps a nice hamfest and party. We expect no problems setting up a repeater here . . . nor with getting permission for all of us to operate.

The second stop will be Berlin, with organized tours (if you like) of both East and West Berlin. Other than this there will be no organized tours. You will be flown to a city, taken to a nice hotel, and provided with breakfast . . . from there you are on your own. We'll recommend restaurants . . . get you in touch with local amateurs . . . and give you the benefit of our experience.

The third stop will be Moscow where we will meet many of the local amateurs . . . and have a party with them. We hope to arrange it so those interested in working DX will be able to operate some of the club stations and talk back home.

The last stop will be Amsterdam . . . more amateurs . . . hopefully a party . . . and more two meter fun, probably with our own repeater.

The trip will last three weeks and will be something you will remember the rest of your life. Nothing like this has ever been done before . . . how about coming along?

In order to keep the price of the trip as reasonable as possible we will be staying at good hotels, but not posh ones. We have always found that the smaller hotels are much more friendly and fun . . . better food . . . better service . . . and an interest in you. You can have the snob places where the desk clerk has a permanent sneer.

The whole trip, based upon double occupancy of rooms, with bath wherever possible, including all air and land transportation, airport taxes, breakfasts, parties, is expected to run about $700 each . . . $1350 for two.

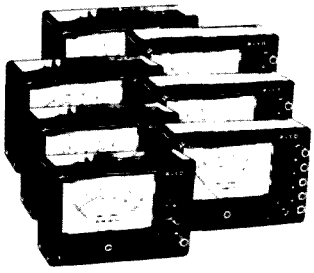
If you like the idea and want to reserve a spot on this trip you may send in a check for $200 down payment for each ticket. This is refundable in full up until 60 days before the trip and in part after that. Final payment will have to be 60 days before departure. Please sign up early so we will be able to handle the amateur radio license registrations and permits for the four countries. We'll send you crystal information for your transceivers to match our portable repeater as well as the many repeaters now on the air in Europe.

Three solid weeks with Wayne Green? Lordy!

. . .W2NSD/1

NEW PRODUCTS

NEW GE VARISTOR



Voltage surges burning up your transistor projects? Need some kind of protection on an IC that is easily ruined by excessive voltage? The answer to the problem is the new GE-MOV varistor made by General Electric. By mounting this device in parallel with the delicate components or circuit the MOV acts as an insulator until a voltage surge occurs. Then the MOV becomes a conductor and the power is safely bypassed from your circuit. The MOV, short for metal oxide varistor, can be used for protection, stabilization, or regulating voltages to components like ICs that can melt with too much voltage. As technology advances, these devices will find greater acceptance in the homebrewer's shack, but in the meantime, they will be used in industrial applications such as TV, relay and motor protection, and other places where solid state controls are found. We'll be hearing more about this in the near future. Contact the *Semiconductor Products Dept., General Electric Co., Building 7, Mail Drop #49, Electronics Park, Syracuse NY 13201.*

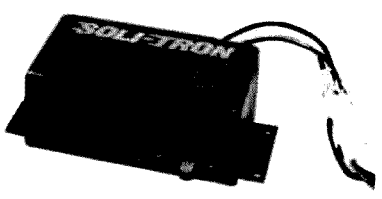
(continued on page 12)

NEW PRODUCTS

Continued from page 11

SINGLE FUNCTION METERS

Experimenters will really like the new single function meters made by ALCO. These meters have multiple ranges, but each is made for only one function (i.e., dc microamp, dc milliamp, dc amp, dc volt, ac milliamp, ac volt, and ac amp). Each meter has a wide face, making reading easier, and the accuracy rating is 1.5%. Low cost makes these easy to own, as the average price per meter is about thirty dollars. Write to *ALCO, 1551 Osgood St., North Andover MA 01845.*



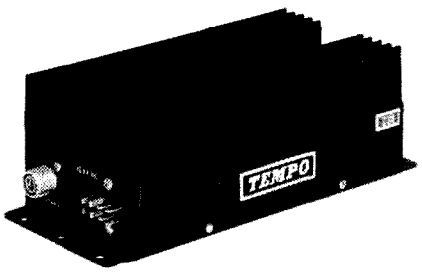
NEW 220 TRANSCEIVER

CLEGG 21er: the first 220 MHz FM transceiver offering the operating features and quality performance that FMers have come to expect on lower frequency bands.

The 21er provides automatic panel selection of ten primary crystal controlled transmit-receive channels and secondary continuous tuning of the 220 MHz FM band. The 21er provides a conservative ten watts output combined with a .25 μV receiver with the ruggedness and reliability of an extruded frame and diecast panel structure.

Scheduled for production in June, the 21er will be priced under $300. Also planned for early release are 220–144 MHz receiver converters and 220 MHz repeater package.

6–12 VOLT DC CONVERTER



Solitron Devices, Inc., announced the release of a 6–12V dc converter for use with vehicles having a 6V negative ground system. The converter will step up a 6V dc source to 12V dc for use with the newer electronic accessories now available for the higher voltages. The converter can be used to supply 12V dc for use in powering AM-FM radios, auto stereos, tape deck equipment, amateur communications equipment, and other accessories.

The converter also has 6 amp output – continuous, a switch and pilot light to insure converter is working, puts out up to 72W, has a one year warranty, and fits conveniently in trunk area or under dashboard of vehicle. For further information contact *Solitron Devices, Inc., 256 Oak Tree Road, Tappan NY 10983.*

LOW COST I.C. POWER SUPPLIES

Viking Electronics, Inc. has introduced a line of low cost power supplies for logic and linear system applications. Priced from $17 to $24 in single quantities, the OEM 70 Series provides typical outputs of 3.5 to 6V @ 3 amp, 8–15V @ 1.2 amp with regulation of .5 to .1% and ripple of 1 to 2MV dependent on models. Features include electronic current limiting, floating output, stable differential amplifier circuitry, silicon transistors and computer grade capacitors. For more information contact *VIKING ELECTRONICS, INC., 721 St. Croix, Hudson WI 54016.*

IMPROVED TEMPO FM AMPLIFIER

In January we reviewed the Tempo 100 watt amplifier . . . just in time to find that a new model had been released which was even better in almost every way!

The Tempo amplifiers are made by TPL Communications in Hawthorne, California, not in Japan like the Tempo FMV transceiver. They were formerly made by C.T. Power, but the company was reorganized and now is owned by Tom Litty K6RAD, a young designer from TRW, the company that makes most of the power transistors used in the power amplifiers on the market today.

The new 120 watt amplifier has printed circuit coils, with about the only things sticking up at all being small lumps for the driver transistor and the three parallel output transistors, some flat by-pass capacitors and small tuning capacitors. With 10 watts in you definitely do get 120 watts out – this is exactly what I measure in my car using the Standard 826M as a driver. It does make a difference too! With the ten watt signal I can generally lift repeaters that are coming in an S-4 or so the 120 watts puts me through repeaters that are less than S-1, but still are readable

If all of my contacts were made parked on the top of my nearby mountain, I wouldn't have much use for the higher power. But one of the problems of living in the mountains is that most of the time I am driving with a mountain between me and the repeater I am talking through. This is where the power helps a whole lot. After all, if I can hear the repeater, why shouldn't I use enough power to get into it from wherever I can hear it? That seems reasonable to me and the 120 watt Tempo does this job beautifully.

Tom has added some other extra to the new amplifier; little plus details. There is now a jack for plugging in a control switch to turn the amplifier on and off, keeping down your battery drain when the extra power output isn't really important. Once your repeater is coming in over S-6 or so you probably won't need the pair of shoes and your car may appreciate holding onto the 17 amperes.

Perhaps it's a small thing, but I appreciate the addition of a power output plug instead of a cable hanging out with a UHF connector on it. Once the unit is in place under the seat of my car it doesn't make any difference, but when I go to take the amplifier out for a trip (I take it with me when I fly and use it in rented cars), it greatly simplifies the change.

The TPL amplifiers were on display at SAROC and were one of the hits of the show! The wattmeter used for the demonstration showed that the amplifiers were rated conservatively and that 140 watts out of the 120 watter was not uncommon.

The promised 220 MHz TPL transceiver drew much attention too and is due to be produced soon. The company reorganization put them back a few weeks. There are, I understand, well over 200 back orders for this unit, so perhaps we will start seeing serious 220 activity in the near future. The most important product promised from TPL is a 220 MHz repeater. Once that is available we can start populating the band in earnest. I look forward to the day when virtually every repeater club has a 220 MHz repeater as well as one for two meters.

TPL has quite a wide range of amplifiers for two meters, six meters, 220 MHz and 450 MHz. Their two meter amplifiers are designed to work with any of the commercial transceivers, from the one watt output Drake TR-22 up to the 25 watt Gladding and Simpson units. They even have an amplifier that will lift the TR-22 to 100 watts out.

Distributors would do well to contact Henry about handling this line of equipment.

W2NSD/1

The Radio Association of Erie, on April 8, will hold its annual Ham Auction at the St. George's Gym. The auction starts at 2:00, and it is expected to be a good one. The gym is located 1½ miles north of I-90 on U.S. Route 19. Free map and details from RAE Auction, Box 844, Erie PA 16512.

* * *

The Southern Tier Radio Clubs are sponsoring their Thirteenth Annual Hamfest for April 15 at the St. John's Ukranian Hall, Johnson City NY at 2 P.M. For tickets and additional information, contact John Pike WA2UKS, 635 Lacey Dr., Endwell NY 13760.

* * *

The Delaware Amateur Radio Club will hold a Horse-Trader and Auction night at the County Engineering Bldg., Kirkwood Highway, Wilmington, Delaware on Wednesday April 12 at 8 P.M. Bring your gear and sell or swap. For further information contact Charles McGonigal WA3AVD, 18 Harvard Road, Wilmington DE 19808.

* * *

The Fresno Amateur Radio Club presents Fresno Hamfest '72 on April 28, 29 and 30. There will be swap tables, transmitter hunts, displays, banquets and more. The convention will be held at the Fresno Hilton. Listen in on 7255 WCARS and 3952 WPSS, or write to Fresno ARC, P.O. Box 783, Dept. HF, Fresno CA 93712 for more information.

* * *

The Rockaway ARC will hold its Annual Spring Auction and FMers Get Together Friday evening April 28, 1972 at 8:00 P.M. at the Hall of Science, 111th St. & 48th Ave., Carona, N.Y. at the old World Fair grounds. Doors open at 6:00 P.M. to accept items for the sale. Two dollar donation at the door will include refreshments. For further information contact Auction Chairman, Al Smith WA2TAQ, P.O. Box 341, Lynbrook, N.Y. 11563.

* * *

Southwest Ham Round-up and Fiasco will be sponsored by Old Pueblo Radio Club April 29–30, 1972. Headquarters Ramada Inn, Tucson AZ. Banquet, technical sessions with ham applications and demonstrations. Ladies, luncheons and tours. Pre-registration prize plus other prizes. Swapfest, auction, and other activities on the 30th. Plan to enjoy the hospitality and fun in the sun. Contact Al Summers W7MGF, Chairman, c/o O.P.R.C., Box 6497, Tucson, Arizona 85716.

* * *

The Young Ladies Radio Club of Los Angeles will hold its Sixth International YLRL Convention. Tours, cruises, talks, meetings, and entertainment will fill the long holiday weekend of May 26, 27 and 28. The convention will be held at the Edgewater Hyatt House on Pacific Coast Highway overlooking the Long Beah Marina. Registration of $12.50 goes to $14.00 after May 15. Further information can be obtained from the Convention Committee, P.O. Box 3092, Long Beach CA 90803.

* * *

The Fresno Amateur Radio Club presents Fresno Hamfest '72 on April 28, 29, and 30. There will be swap tables, transmitter hunts, displays, banquets and more. The convention will be held at the Fresno Hilton. Listen in on 7255 WCARS and 3952 WPSS, or write to Fresno ARC, P.O. Box 783, Dept. HF, Fresno CA 93712 for more information.

GEORGIA QSO PARTY

Starts: 2000 GMT, Sat., May 13, 1972.
Ends: 0200 GMT, Monday, May 15, 1972.

The eleventh annual Georgia WSO Party is sponsored by the Columbus Amateur Radio Club, Inc. There are no time or power restrictions and contacts may be made once on phone and once on CW on each band with the same station. Each complete contact counts 2 points. Georgia stations multiply their total QSO points by number of different states and Canadian provinces worked. DX stations may be worked for QSO points but do not count as multipliers. Out-of-state stations will use the number of Georgia counties worked for their multiplier (a possible total of 159).

Write to CARC, Inc., Attention: John T. Laney K4BAI, P.O. Box 421, Columbus GA 31902 for full information on the contest.

MARYLAND

Potomac Area Hamfest will be held at Westminster, Maryland, on Sunday, April 30th, 9:00 to 5:00. $2 registration covers flea market and tail-gate sales. Professional food and beverage catering on grounds. Parking for 400 cars. Usual hamfest activities. FM talk-in on 146.94. Details from K3LNZ, K4LHB or W3EVF.

1972 NEW YORK STATE QSO PARTY

This contest is open to all amateurs and SWL's in the world.

Times: 1700–0500 April 29 through April 30 GMT; 1200–2350 April 30 GMT.

Calls: In State: CQ NY TEST; out of State: CQ NY.

Exchange: QSO number, RS(T), QTH – out of state stations use ARRL sections; NY stations use counties.

Scoring: Score one point per contact on 80 10; two points for each 160, 6, or 2 meter contact; times number of multipliers.

Logs must contain date and time, band, mode, station worked, QSO number, QTH. First new contact for each multiplier numbered.

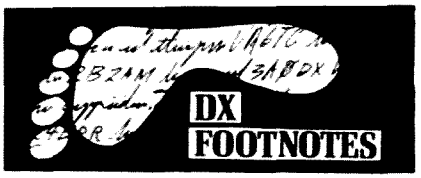
Certificates will be awarded to top scoring station in each ARRL section, country, and NY county. Special Novice and Technician certificates will also be given. Second and third place awards will be issued at the discretion of the contest committee.

Logs, comments, photos, etc. should be sent no later than June 1 to LERA ARC Contest Committee, Jeff Ronner WB2AEQ, 35 Gottlieb Drive, Pearl River NY 10965. Stations planning operation in NY are urged to contact LERA so they can plan for coverage of all counties.

THE FOURTH RTTY WAE DX CONTEST

RTTY WAEDC '72

The Deutscher Amateur Radio Club (DARC), the sponsor of the RTTY WAEDC, and the Deutsche Amateur Fernschreib Gruppe (DAFG), the manager of the RTTY WAEDC, have the honor to invite RTTY amateurs all over the world to participate in the 4th RTTY WAE DX Contest 1972. This contest is always held on the last weekend of April.



1. CONTEST PERIOD: April 29, 0000 GMT to April 30, 2400 GMT.
2. CONTEST CALL: CW WAE de . . .
3. SCORING: The final score is the total QSO points plus QTC points multiplied by the sum total countries from all bands.

Contact WAEDC officials for further information: *WAEDC - Committee, D-8950 Kaufbeuren, P.O. Box 262, Germany - West.*

COLUMBUS GEORGIA HAMFEST

The fourteenth annual Columbus, Georgia, hamfest will be held on April 9, 1972 at the Fine Arts Building behind the Municipal Auditorium at the Fairgrounds. For information, write J. T. Laney, K4VGI, 1905 Iris Drive, Columbus GA 31906.

(continued on page 14)

According to the *Mobile News* the Journal of the Amateur Radio Mobile Society, the following members have attained new status in the Mobile Century Award Listings: W6KZL/m 236, F3DJ/m 221, G3BID/m 201, SM5RQ/m 190, DL6UH 160, W4NEW/m 140, G3TJY/m 121, WA3HDU/m 108, G3KNB/m 103, WA4WTK/m 102, and DJ3LF/m and WA2FQG/m, 101 apiece.

Gus reports in the DXers Magazine:

W3QLW has received the Arabian Knights certificate which states on a beautiful document, "The Arab Radio Amateur League has the pleasure to certify that Mr. Oscar G. Herrick, W3QLW, has contacted ten Arab countries and has been granted the Arab Knight award in significance of being a dear friend to all Arab Radio Amateurs. League Chairman (signed Hussein, JYL) Date 30 Sept. 1971 No. 27."

C31DP will be active for three weeks in June, so says Omer ON5TO who should know; it is his second call.

Between Ed, W8KGR, and Guy, TR8DG, the French Community Net is handled very well. The net meets on Mondays and Wednesdays at 1930Z on 21,390. Plans are to increase activity to four days per week operation and they want many check-ins.

If you are looking for TN8BK, try around 1400Z near 21,330 up. As a doctor, Bernard does not have too much time for operating.

Les, ZD9GA, has been active from Gough Island on 20 SSB. Most of his operating seems to be list type work. QSL via ZS2RM.

7X2BK has been heard on 20 SSB, around 14,236 about 2000Z. Listen carefully as he is using transceive and an indoor antenna.

Every Wednesday Robert, 9U5CR, holds skeds with his QSL manager Omer, ON5TO, at 1800Z on 14,280. He is QRV for others after they are finished.

Tapei is active now that BV2AB, Bob, is on the air. He is the first American to be licensed there in several years. Look for Bob 14,230 from 2300 0130Z. Sends QSLs via K4ASI.

Contact Mary, WA3HUP, if you need help in working CR3KD on Portuguese Guinea. They have skeds twice a week on 15 and 20.

Nauri Island, C21TL, can be found 14,200. This station will be on the air for about three years. FB8ZZ, on the other hand, will only be active for another month or two. FH8CG can be heard near 21,285 about 1700Z. And FM7AA is at 14,222 about 1240Z.

JX2HK has been worked on 14,038 about 2000Z. This is Jan Mayen Island.

* * *

From CARF, we learn that . . .

ONTARS – Ontario Amateur Radio Service has commenced operation on 3775 kHz. Hours of operation are from 7 AM to 6 PM E(D)ST, daily. This is a call-in net similar to ECARS on 40 with the prime object of providing two-way facilities during the daylight hours throughout Ontario. Congraulations go to the Radio Society of Ontario for sponsoring the net and to Bruce Carveth VE3BC, ONTARS net manager.

* * *

And from the West Coast DX Bulletin .

An international group claims to have established an away-from-it-all republican state on the desolate sea-washed Minerva Reefs in the Pacific about 450 miles south of Fiji. Fiji has been asked to recognize the state, established by the self-styled Ocean Life Research Foundation of New York and London. Two dredges are due to arrive at the reef in three weeks to begin reclaiming up to 400 acres of land on Minerva. Mark Oliver, a U.S. Citizen who said he is one of the three directors of the foundation, said in Suva their intention was initially to build a port and later a sea city as a haven for people who wanted to escape from crippling taxes, riots, crime and drug addicts. "We decided on Minerva after a worldwide search because research showed conclusively that the reefs do not belong to anyone," he said. "By International Law one can claim by annexation only land above the sea that can be built upon. We have met this requirement by constructing two small islands of coral and sand on the reefs." Oliver said the Ocean Life Research Foundation, established 18 months ago and backed by scholars throughout the world, was serious about a sea city republic at Minerva. International engineering companies had been consulted and expenditures on the project, so far, totaled $180,000, he added.

* * *

QSLs for 3D6AO, Swaziland, may be sent to P.O. Box 1, Mhlume Tshaneni, N.E. Swaziland.

Nigerian Amateur Radio Service and Joe, 5N2AAJ only accept incoming QSL cards for Togo, 5VZ and TJ and they are not responsible in any way for outgoing QSL cards. All incoming cards are passed on to 5VZ immediately and after that their responsibility is ended.

The Liberian Radio Amateur Association sponsors a West Africa Net on 7060 at 0800Z each Sunday. So far 9G1, E12, 9L1, and 5V7 have joined in.

* * *

Some of the current active "DX-pedition of the month" stations: HP1IE/3F1IE, JW1EE, KF4SJ, PJ7VL, VA2UN, VK9JK, VK9XX, VK9XK, VP8JV, VS6DO, VS6DR, and 9Y4VT.

* * *

MCAS IWAKUNI, Japan, Oct. 5 — Captain James W. Jackson is a quiet man, but his voice has been heard all over the world. The 32-year-old native of Rochester, N.Y., operates KA5JJ, the only authorized amateur radio station here. Captain Jack-

SOCIAL EVENTS & CONTESTS

(continued from page 13)

7th WORLD ORCHID CONFERENCE AMATEUR RADIO CONTEST

The contest has been organized by the "Liga Colombiana de Radioaficionados, (Zona 4a) and is sponsored by the 7th World Orchid Conference. It begins at 0000 GMT, Saturday, April 8, 1972 and ends at 2400 GMT, Sunday, April 9. AM and SSB in phone only. 5J4LR and 5K4LR will also be on the air. Multi-operator stations not allowed. Exchange: HK4 stations, RS plus a 3 figure number indicating the power of the station. Other stations, RS plus a 3 figure contact number, starting with 001.

Points: For stations not in North, Central or South America – contacts with HK4 stations, 5 points, contacts with 5J4LR or 5K4LR, 10 points. For stations in North, Central or South America – contacts with HK4 stations, 3 points, contacts with 5J4LR or 5K4LR, 5 points.

The same station may be worked on each band for multiplier credit.

Final score: the result of multiplying the total number of points by the number of bands worked.

Mailing deadline: June 9, 1972, to: LCRA, Seccional Medellin, Apartado aereo 51900, Medellin, Colombia, South America.

LETTERS

I read with interest your editorial in Jan. 72 issue of 73. I fully agree with you that the amateurs made a big mistake by operating their repeaters with only .6 MHz spacing. The problems encountered at 1 MHz is a fraction of problems and cost involved with cavities and duplexers.

Let's not get ourselves into the same fix when we go fully duplex. The phone company operates mobile duplex with a frequency spread of 5.26 MHz in the 150 MHz range. It is possible to make mobile duplexers extremely small to fit right inside the mobile. "Systcoms" duplexer measures only 4 x 3 x 1½ in. for telephone applications. The two meter hand has a 4 MHz spread so why not use 3.5 mHz spacing and 220 has a 5 MHz spread so why not use 4 MHz spacing. Someone may come up with the argument that the spread is too great if you want to operate simplex also. The answer is the mobile manufacturers are learning how to broadband amplifiers so operating a transmitter over a 1 MHz range is possible. Recently I evaluated an IC-20 and found that the transmit power dropped only about 15% with two channels separated by 3 MHz. Let's get on duplex the right way. The same desensing and noise problems we are having now with repeaters will occur if we operate mobile duplex with a close spacing.

Some frequency coordination is required now before it is too late.

Vern Epp
Nelson BC

Other opinions on input and output spacing are invited. If we had it to do all over again, would we do it this way? Let's plan 220 and 450 with the wisdom of past learning.

son, assigned to Marine Wing Headquarters Squadron (MWHS)-1, 1st Marine Aircraft Wing, explained that KA5JJ is operated with equipment on temporary loan from MCAS Special Services, and some home-made items. The station, officially named an Auxiliary Military Radio Station (AMRS), broadcasts international Morse code. Although it has voice capability, Capt. Jackson chooses not to use it.

Permission to operate aboard MCAS Iwakuni was granted by the commander of U.S. Forces in Japan, through the commander U.S. Naval Forces Japan, and the commanding officer of MCAS. It was granted on the basis of Capt. Jackson's advanced class operator and station licenses, issued by the U.S. Federal Communications Commission.

Twenty years and nearly $6,000 have gone into a station he owns in the U.S., from which he broadcasts both voice and code to such countries as Russia, China, Chile, France, Sweden, and many others. Jackson moves the equipment with him when he is transferred within the U.S.

"Language is not that much of a problem," he states. "Most amateurs throughout the world know how to give their call sign, location, name and other important information in English."

Capt. Jackson is credited with helping to set up the MARS network in the Republic of Vietnam. While he was there, he conducted classes on amatuer radio operation.

RACES FREQUENCIES

In regard to your editorial concerning repeater frequencies, I feel you are on the right track. Something else you might consider would be to match these channel frequencies with the authorized RACES frequencies. We can hope never to be confined to these frequencies, but this could help improve the status of amateur radio. Also, it could conceivably make available some ideal repeater sights.

Keep up the good work.

Van. A. Sears WA4SQS
Columbia SC

How do other people feel about synchronizing standard repeater channels with RACES frequencies? There is a lot to be said on both sides.

CORRECTIONS AND AMPLIPICATIONS

Modified Heathkit HW-16 CW Xcvr page 101, Feb. 1972 – caption under Fig. 1 should be under Fig. 5 and vice versa. Also caption under 2 should be under Fig. 4 and vice versa.

John Edgerton WA3PRV

Re - CKT Page 98 (Feb. 73 Mag) - "Variable Power Supply" by W4IOI. Please note - 100K pot - if set to minimum, shorts out basic 320V supply. "Come on guys, you can do btr than that."

Cliff Whipple W5VRT
Morgan City LA

No we can't.

REVISED MORSE

Some years ago a musical genius developed and patented a piano keyboard with a system of tiered tabs that was the acme of simplicity. No black notes for the fingers to slip off of, fingering was standardized regardless of what key the pianist was playing it.

It doesn't require much thought to figure out why this invention is gathering dust in the files of the patent office, and I venture to say that a revised Morse code, patented or not, would suffer the same fate for the same reason.

Harry Sorensen W7IH
Friday Harbor WA

HELP WANTED

I am a student anthropologist taking an anthropological look at ham radio for my Senior thesis. My goal is to provide the public (both college and community) insight into the people who make ham radio what it is – the hams. I need your help.

Here is your chance to sound off. Just write me a letter and tell me about your hobby – ham radio. You can tell me things like what you like to do best within ham radio (DXing, phone, CW, nets, etc.), what you think the ideal ham should be like, what you think of your fellow hams. Tell me about your equipment. If you're a phone man, how do you feel about CW, SSB, AM, or if you're a DX'er how you feel about AM, etc. What do you think of the ARRL? The FCC? How long have you been in ham radio? Do you buy gear or make it? What are your favorite bands? Do you belong to a net . . . club . . . which ones? What do you think of CB'ers? Just tell me about anthing you can think of that you'd like to talk about on the subject of ham radio.

I assure you that (1) I am a genuine anthropologist doing bona fide research with the approval of the ARRL, and (2) your names will be held in the strictest confidence and (3) I'm not some salesman or kook trying to get your names for a mail order firm. In fact, you don't need to sign your name or give me your address; just be sure that if you write that you state whether you're a ham and what license you have. This is very important for my data.

With your cooperation I hope to confirm some of the generalizations that I have made in my research. In fact, I may even have to confirm that no one great generalization can be made about hams! With your information I hope to get an overall picture of the people that are ham radio.

Thank you very much for your time and attention.

David Silver WN1PLC
Box 545, Troy NH 03465

Send your comments to David Silver, Franklin Pierce College, Box 885, Rindge, NH 03461.

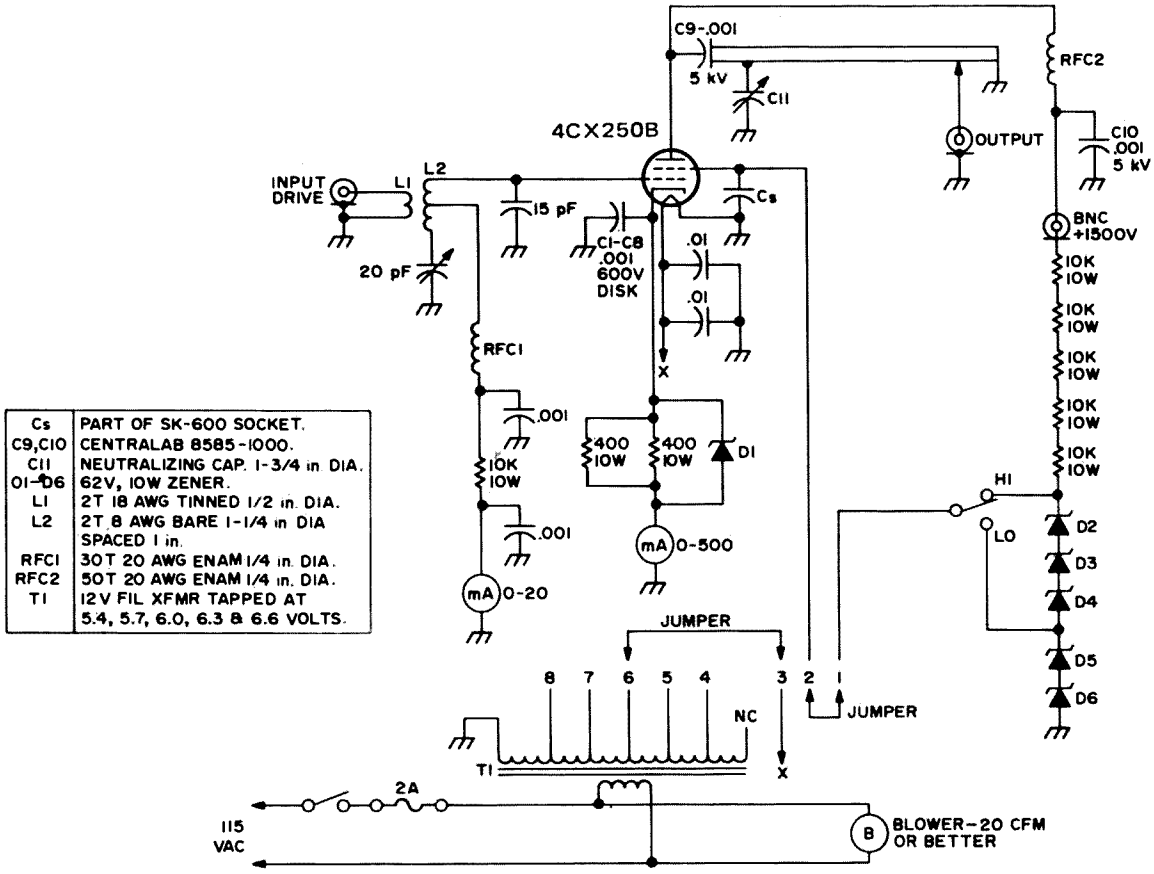
Power Amplifiers for Two Meter FM

A simple and compact power amplifier to boost transceiver output



With the increased popularity of 2m FM has come an increased need for additional power to boost the range of surplus FM transceivers. This amplifier is designed for such service and operates with only 5W of drive to produce outputs in the order of 200W.

Simplicity is the keynote in the design and construction. It uses no silver plate, no neutralization, no bias supply, no screen supply, no grid loading, no plate loading capacitor, and suffers no damage if drive is lost. In addition, there is no necessity for protection of the tube in case plate voltage is lost since screen and plate voltages are provided from a common supply.

The amplifier derives all operating voltages from the plate supply and plate potentials may be used ranging from 750 to 1600. The most efficient operation, however, lies in the region between 1300 and 1600. Screen voltage is dropped from the plate voltage by five resistors totaling 50 kΩ. Five zener diodes stabilize the screen voltage and do not allow it to exceed 310V. Any combination of zeners may be used. The 62V 10W zeners used here were chosen because of their avail-

Grid input is at lower left, plate output at upper right. BNC connector at lower right connects to plate supply, switch on right changes screen voltage. Filament transformer on left is tapped to allow adjustment of filament voltage.

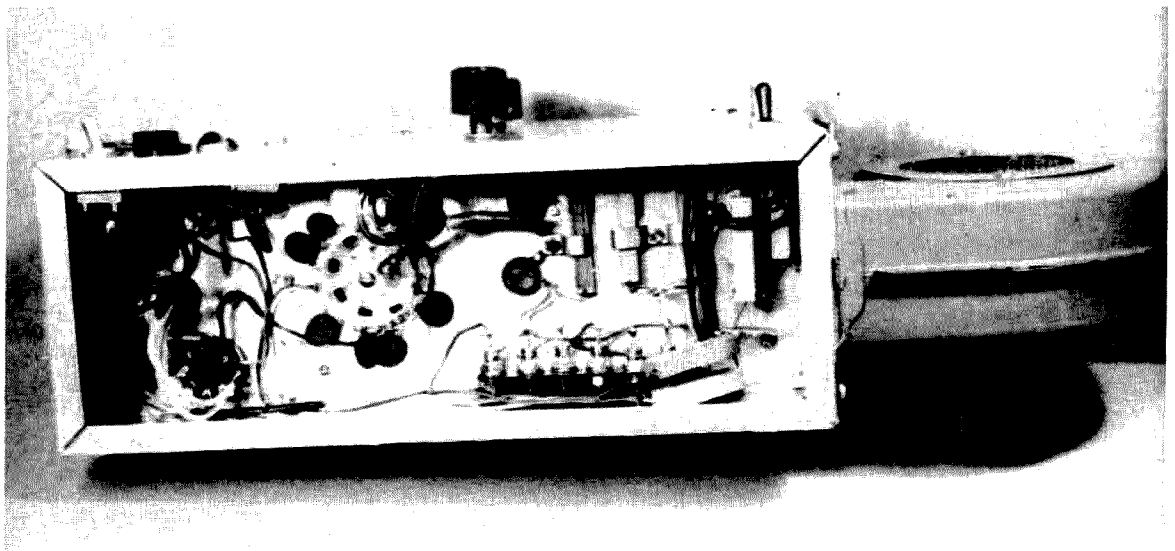
ability on surplus at two for a dollar (Delta Electronics, Lynn, Mass.).



A single-pole double-throw switch changes screen voltage from 310 to 124V, allowing reduced input for tuneup or local work. Those interested in a greater range of power control may install a four-position rotary switch to tap into the zener string at each junction. All dropping resistors and zeners are located below the chassis directly in the air stream from the blower.

If zeners are not available, two VR-150 gaseous regulator tubes may be used, but the chassis will have to be made larger to accommodate the sockets.

If it is desired to monitor screen voltage and current, an octal socket is mounted behind the filament transformer. The jumper may be removed from pins 1 and 2 and a milliammeter inserted to check screen current during operation. If screen voltage readings are desired, the jumper is left in place and a voltmeter clipped to the jumper and to ground. If there is any doubt regarding the screen dissipation, it is suggested that the manufacturer's specifications be consulted.

Because of this system of deriving screen voltage, an external screen supply is not needed. The price paid for this benefit is the use of zeners and dropping resistors, but mounting them under the chassis tucks them away neatly and the blower keeps them cool.

Control grid bias is supplied by the drive in a conventional manner and protective bias is developed across a 200Ω cathode resistor shunted by another 62V 10W zener. In this manner the cathode bias protects the tube and provides a minimum voltage at all times, while the zener clamps an upper limit of 62V on the bias, allowing the tube to handle more power at high current. A zener may be used in the cathode lead without the resistors, but it

Bottom view of amplifier with cover removed. Zener regulators on copper heatsink area are at lower right, screeen dropping resistors, bias and cathode resistors at upper right located in air stream of blower for better cooling.

operates too close to maximum ratings for good design.

Manufacturers recomend a screen voltage of 250V on the screen of the 4CX250 while this dropping network places 310V on the screen instead. When calculating screen dissipation be sure to take into consideration the fact that the cathode is at 62V above ground, making the actual screen voltage 250 with respect to the cathode.

Filament voltage is provided by a 12V 5A transformer tapped on five consecutive turns. Specifications call for 6.0V on the filament of the tube and it may be desired to adjust this voltage to compensate for variations in line voltage and tube aging.

To tap into the windings, remove the shell and outer layers of insulation, exposing the heavy turns of the secondary windings. Plug the transformer primary into 115V and measure the voltage on each exposed turn by clipping an ac voltmeter to a razor blade and gently pressing it into the enamel insulation of each turn. The turns to be located are those which show a potential of 5.4, 5.7, 6.0, 6.3, and 6.6V. Most transformers are wound for three turns per volt, so these turns will lie side by side.

Tap into each of these turns with a flexible lead which will later be brought out of the transformer. Pry each turn away from the body of the transformer with the point of a small screwdriver. Cut the wire and solder a small loop of bus wire to the ends and solder the flexible lead to the terminal thus formed. Insulate the loop with a strip of cardboard before pressing back into place. A coating of corona dope or shellac completes the job.

The five new wires are brought out of the transformer to the octal socket behind the filament transformer and terminated on pins 4, 5, 6, 7, and 8. Pin 3 feeds the filament current to the tube, so a jumper from this pin to the appropriate pin provides the proper voltage to the tube. It also allows the operator to monitor the filament voltage when desired by clipping an

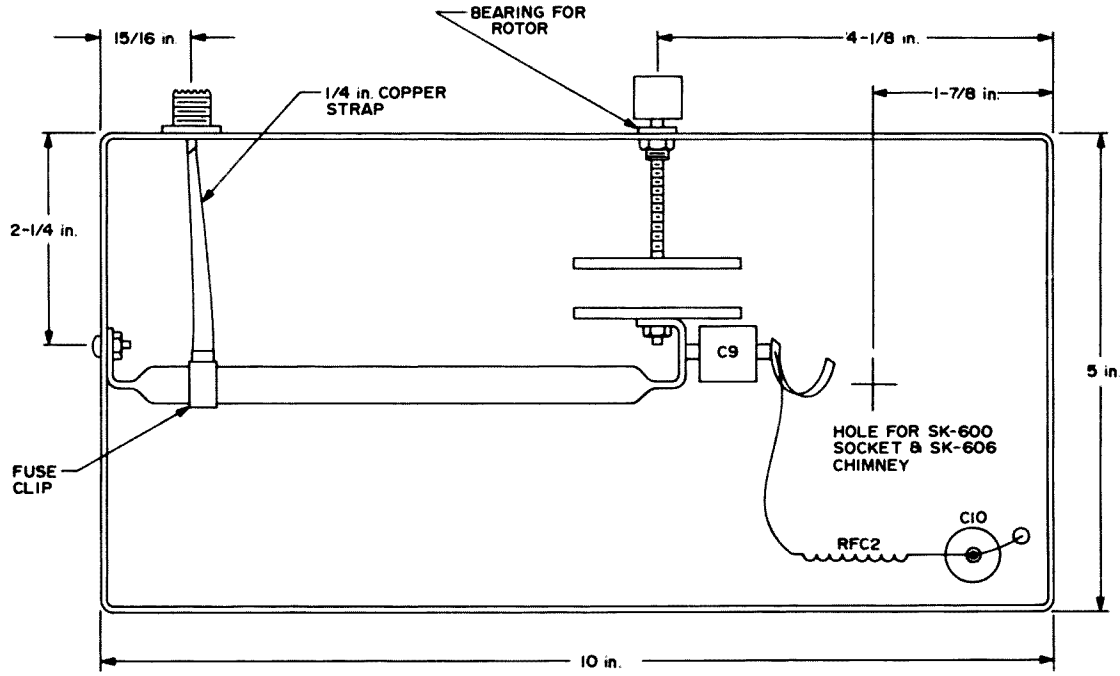
ac voltmeter from ground to the jumper. Monitoring filament voltage on the 4CX250 is normally difficult due to the closed and pressurized grid compartment.

The plate circuit is quite simple and is capable of efficiencies of better than 60%. The plate inductor is formed from a length of "supply line," a chrome-plated brass tube used by plumbers, available at hardware stores for about 75¢. The ends are flattened and formed as shown into a 6 in. length. The cold end is fastened to the chassis while the other end is attached to the plate coupling capacitor and the stator of the plate tuning capacitor. The other terminal of the coupling capacitor is



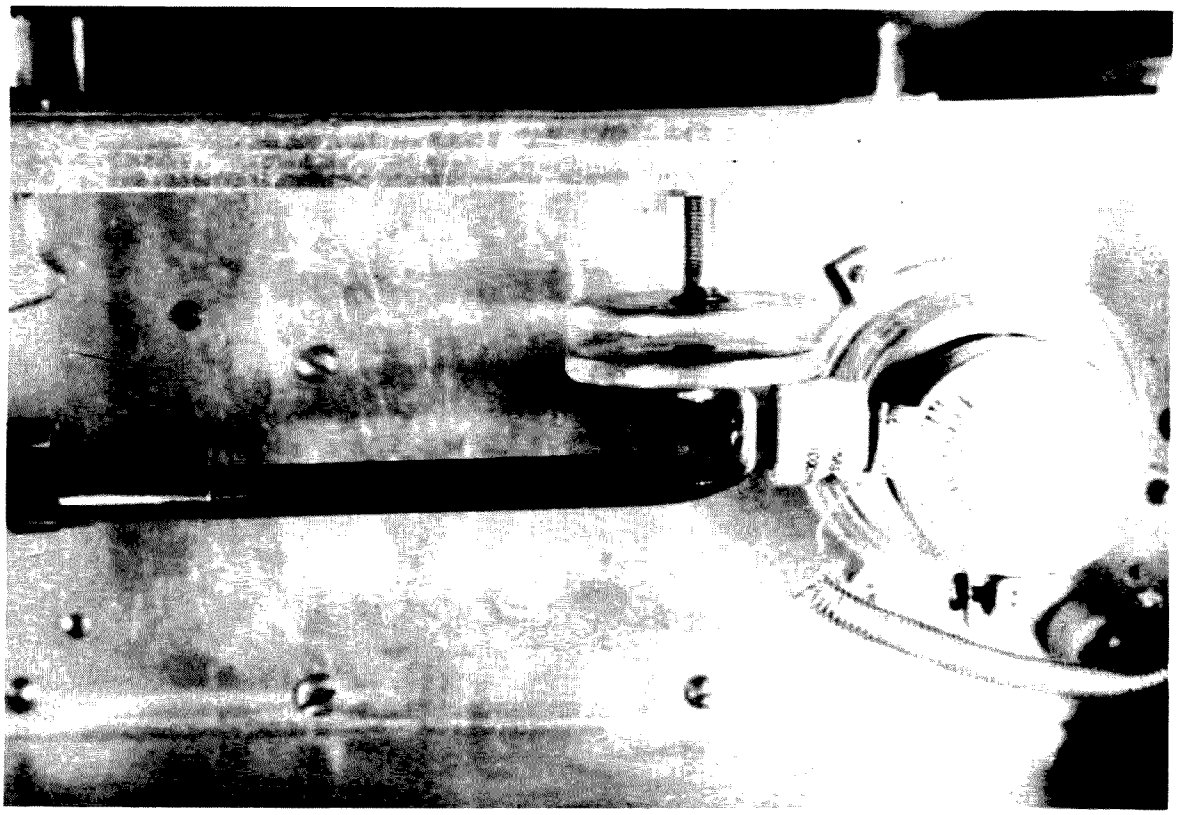


Fig. 3. Detail of chassis.

Tube and plate assembly showing coupling capacitor and bypass at lower right. Coupling capacitor is held to tube by a copper collar and short strip of brass shim stock. Plate line is a length of chrome plated supply pipe.

screwed to a small strip of shim stock which is clamped under a copper collar encircling the tube. The copper collar is held in place with a brass machine screw.

The plate tuning capacitor is made from a National neutralizing capacitor with plates 1¾ in. diameter; the movable plate is supported by the original bracket bolted to the front panel. The shaft extends through the panel far enough to accommodate a plastic knob. Place a small compression spring and a washer between the knob and the panel to spring-load the capacitor, since vibration would otherwise cause it to creep.

If a neutralizing capacitor is not available, one can be made from disks of copper or brass soldered to a 0.25 in. brass machine bolt. In this case the shaft will work into a brass or copper plate screwed to the front panel. Again, don't forget the compression spring.

The only store-bought components in the plate structure are the two high-voltage, high-frequency capacitors (Centralab 858S-1000) used for coupling and bypassing and the tube socket and chimney (Eimac SK-600 and SK-606). The chimney is necessary to force air through the plate efficiently.

The plate choke is formed of 50 turns of 20-gage tinned solid hookup wire with the insulation removed, wound around a 0.25 in. stove bolt. When the bolt is removed the turns will hold proper spacing and can be wired directly into the circuit.

The loading assembly consists of a brass fuse clip chosen to fit snugly on the plate inductor, to which is soldered a copper strip 0.25 in. wide and long enough to reach the output connector. Loading is accomplished by sliding the clip on the plate inductor.

The amplifier is constructed on two chassis, the lower one 5 x 13 x 13 and the upper 5 x 3 x 10 (Bud AC-404 and AC-422) fitted with an aluminum plate on the bottom and a perforated aluminum plate on top to permit air to escape. The two chassis are bolted together with eight brass screws and the tube socket hole cut through both at once. It will not be

necessary to make the grid compartment air-tight if the large blower is used. The blower provides enough air for both components and tube. In order to assure sufficient flow some small holes should be left in the lower chassis. Leave the holes open in the corners of the chassis as octal socket and at the filament transformer with putty or plastic tape.

Parts placement is not critical. Keep components in the lower compartment away from the grid coil which is supported by the tube socket on one end and the grid tuning capacitor on the other. The grid

plate choke, but with only 30 turns. It is necessary to use dissimilar chokes to avoid possible oscillation at the resonant frequency of the chokes. Bypassing of the cathode is accomplished by soldering in two disk capacitors at each of the four cathode terminals. It is not necessary to bypass the screen since this is done inside the socket itself.

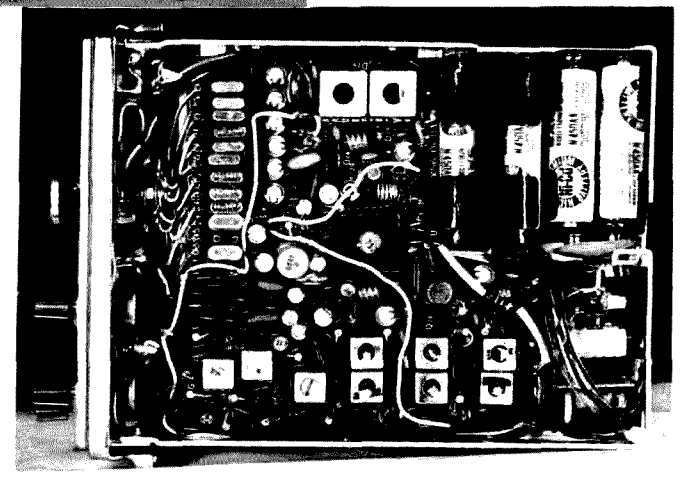
Plate-voltage connections are made through a BNC connector. These connectors seem small and subject to arc-over but in practice operate well up to 2000V and are readily available on surplus. A jumper of RG-58/U coaxial cable equipped with male BNC connectors may be used from the amplifer to the power supply. This also provides a ground connection along with the high-voltage connection for greater safety. Even with this method, an added precaution would be to run another ground from amplifier to power supply separate from the one above.

To place the amplifier in operation put both top and bottom covers in place and energize filament and blower. Connect a wattmeter and dummy load to the output connector and a low-power 2m transceiver to the grid connector. Activate the transceiver and tune the grid to resonance indicated by a reading of 5–20 mA on the grid meter. At the same time the cathode current will indicate since the same current flows through this meter but the indication will be small.

If the drive is satisfactory, place the screen switch on "low" and apply plate voltage. Plate current will rise to about 60 mA. Tune plate for maximum indication on wattmeter. Some mechanical adjustment may be necessary between the rotor and stator of the plate capacitor. Loosen the collar around the tube and shift the position of the shim strip to place the stator in a better position relative to the rotor. Form the habit of always turning off plate voltage before removing the top cover.

If the plate tunes as it should, adjust the loading clip by inserting a tuning wand through the perforations and shifting its position until an optimum position is found which produces maximum output. Retune the plate after each change. In the amplifier pictured the optimum position was found to be 0.75 in. from the cold end.

At this point you should, with about 1600V on the plate, see about 40W on the wattmeter. Change the screen from low to high and retune the plate. It may be necessary to shift the loading clip slightly on high power. Plate current should now stand at 180 to 220 mA and output power should increase to about 200W. Turn off the amplifier and replace the dummy load with the antenna, again optimizing the tuning. The tube runs warm under these conditions and if a hand is held over the tube hot air may be felt exhausting from the tube.



To calculate plate input and efficiency, allowances must be made for the cathode bias. If 1600V is used on the plate, the actual plate voltage will be 1540. If 200 mA is indicated on the plate meter, grid bias must be deducted. 10 mA grid current would have to be deducted from the 200 to give a plate current and screen current (combined) of 190 mA. If measured screen current of 20 mA is deducted from the 190 mA, then the actual plate current is 170 mA. Thus, the adjusted plate current must be multiplied by the adjusted plate voltage to arrive at the actual input power of the tube.

If trouble is encountered at any step, check wiring, components (even new components are sometimes defective), solder joints, and the tube. It would be wise to obtain a used 4CX250 or 4X150A for tuneup purposes. Many FM and TV transmitters retire these tubes when emission drops. It would be better to use an old one for tuneup after which a good tube can be substituted for full power. . . .W4RIZ

DRAKE TR-22

DRAKE TR-22

Of all the FM units available to the ham today the Drake TR-22 is unquestionably the most versatile and is an exceptional buy. If you are just getting started in FM and are looking around for a really universal rig the TR-22 is the one that will work on base mobile or portable with nothing else needed other than the possible exception of a mobile or base antenna (if you're more than 25 miles from your nearest repeater). This little gem is the result of Drake getting it all together, and what a package it is, too. Here is a 6 channel unit that you can sling over your shoulder that has state of the art circuitry, a little slim hand mike with retractable cord, internal rechargeable batteries, with built in charger and an internal telescoping antenna.

Coming back from SAROC on a United flight we asked the captain if we could use the TR-22 in flight. Not only did he give us permission but he had us moved from tourist up to first class so we wouldn't be right over a wing that might mess up our radiation pattern. Having those 6 channels on the little portable unit was a real joy, for as we left Las Vegas we said our goodbyes on 94 simplex and then switched to one of the local repeater channels. We talked the repeater out a hundred miles or so and then went back to 94 for a while. As we approached Denver we started hearing their 34/94 machine so we switched over to them. After a few QSO's we went the 28/88 route for some more. Upon arriving back at Boston's Logan airport it was even possible to hit the 73 repeater on 19/79 on top of Pack Monadnock Mountain some 70 miles distant. Admittedly our repeater is 2,000 feet in the air but 70 miles is still quite a haul with a watt and a half!

Before going out to SAROC we had crystaled the TR-22 up for the trip and with the popout case of the TR-22 it was a very simple matter to change the crystals around as they are all on top of the board right out in the open. Strapping is very easy, too, as each crystal has a terminal post right by it and jumpers go right in where they are needed The transmitter warp trimmer capa-

citors are right by the transmit crystals and the receiver does not need any warp capacitors. Changing crystals is very easy because to get the TR-22 out of the case you don't even need a screwdriver. All you do is pull out the two little snap releases on the bottom of the case and the unit slides right out.

Using the TR-22 mobile is a snap as you only have to plug in the external dc power cord (so you save your ni-cads for portable operation) and plug in your mobile antenna. The little unit is so small that you can easily slip it into the glove compartment. Thus the chance of theft is greatly reduced. It takes only seconds to unplug the dc power cord and mobile antenna so you can take it with you if you don't want to leave it in the car. At this point you just pull up the internal telescoping quarter wave whip and you are working as a portable.

It is interesting to note that the TR-22 comes with a complete set of ni-cad batteries as part of the unit – not another accessory that you have to purchase. The same is true for the built in battery charger – it's all inside the unit with nothing else to buy. When you are at home just plug in the ac line cord and the batteries get recharged overnight. If you want to monitor at home or work the boys a little bit, the battery charger gives just enough current to operate the receiver so it doesn't pull your ni-cads down. Of course when you are listening with the ac plugged in, the ni-cads do not get charged until you cut the power switch off. If you transmit while you're at home then that additional current comes out of your ni-cad batteries. To check the condition of the batteries just turn the squelch control all the way counterclockwise and the S/ rf output meter gives you a battery voltage reading. This same little meter automatically works like an "S" meter on receive, so you can find a 'hot spot' if you're having trouble getting into the repeater. On transmit the little meter gives you a relative rf output indication so you know that you are getting out and also gives you some indication of how your batteries are doing under a heavy load. When your output power starts to fall off too much, a quick battery check will reveal that the batteries need a charge. The ac power cord or any of the external power or antenna cords can be plugged right into the bottom of the TR-22, even when it is in its carrying case.

The Drake TR-22 is a very rugged trouble-free unit. Recently when the 73 repeater (19/79) pooped out up on top of Pack Monadnock and there was quite a bit of snow on the access road, we slung the little TR-22 over our shoulder before mounting the snowmobile in zero degree weather. While going up the mountain we got a little carried away and hit an ice ridge and a big wipe-out occurred. After sailing off the snowmobile I landed spread-eagled right on top of the TR-22! Picked myself up and checked back in with K1NUN with no problem at all. After finally getting up on top of the mountain we worked in unheated buildings for a couple of hours and all the while using the little rig. With this kind of use that our TR-22 gets, it has got to built like the proverbial brick house. The TR-22 has proved so reliable that Drake has had very little warranty work to do and as a result has held the $195 price even though the U.S. dollar has been devalued by almost 20% in Japan.

Drake rates the TR-22 transmitter at 1 watt (conservative) but we keep measuring 1.5 to 1.6 on the Bird Termline in our lab. The receiver is rated at less than 0.5 μV but actual testing shows very near 0.3 μV. The receiver is double conversion with an FET rf stage and a ceramic filter in the 455 kHz stage. The first i-f frequency is the standard 10.7 MHz. IC's are used for the second i-f limiter and also for the af output. The TR-22 utilizes all solid state switching (no relays) for maximum reliability. The instruction manual for the TR-22 is very complete and easy to understand. It contains all of the operating instructions, labeled schematics with voltage charts for all transistors and IC's, complete pc board pictorials that are also labeled, and complete crystal data.

The Drake TR-22 is a fantastic little piece of gear and one of the most versatile units we have ever seen with so many normally optional features built in as standard features. Its performance is as amazing as its low price. It is truly a universal rig.

AN AUTO-BANDWIDTH SELECTOR UNIT

This experimental unit attempts to set the bandwidth of a receiver automatically in accordance with QRM conditions. Although described as an outboard unit, the circuit switching arrangements described can also be wired internally in many receivers.

Many commercial receivers and even some transceivers have provisions for the independent switch selection of various i-f bandwidths for reception purposes regardless of the transmission mode (AM, CW, SSB, etc.) switch setting. Generally, most operators like to use a wide bandwidth when a band is not crowded, because of the tuning ease involved, and then switch to a narrower bandwidth as QRM conditions develop. It would be very handy, however, to have the receiver automatically switch to an i-f bandwidth appropriate to the QRM conditions. Such operation would be particularly desirable, for instance, when one is working a station and using a wide bandwidth and then suddenly a strong QRM signal appears. Usually, before one can readjust the receiver, some portion of the transmission will be lost.

This article describes an outboard receiver accessory unit which was developed to provide automatic bandwidth selection. The unit is complete in itself and makes an ideal accessory unit that can be added to a receiver or transceiver that does not have selectable i-f bandwidths. In the case of units which already do have selectable i-f bandwidths, the switching circuits used can be adapted in most cases to work with the installed i-f filters. The unit provides for two automatically selected bandwidths (which can be chosen for either phone or CW service), although the basic scheme can be expanded to include a greater number of bandwidth positions. A manual override switch is provided for manual selection of either bandwidth position.

Basic Operation

Figure 1 shows a block diagram of the basic stages involved in the selector unit. The filter stage is placed between the i-f stages in a receiver. It is controlled, through the other stages shown, by the level of the i-f signal preceding the filter stage. The amplifier stage boosts the i-f pickoff signal and then the output of this stage is rectified to provide a dc control voltage. The dc control voltage in turn operates a Schmitt trigger stage which operates a diode switch for bandwidth selection. The i-f pickoff is taken after the first i-f stage and not directly after the last mixer stage, so the unit will not respond to signals greatly outside of the normal i-f bandpass. The pickoff could be taken after the filter stage, but this will not provide as sensitive a response with receivers having good avc/agc action, since signals passing through the

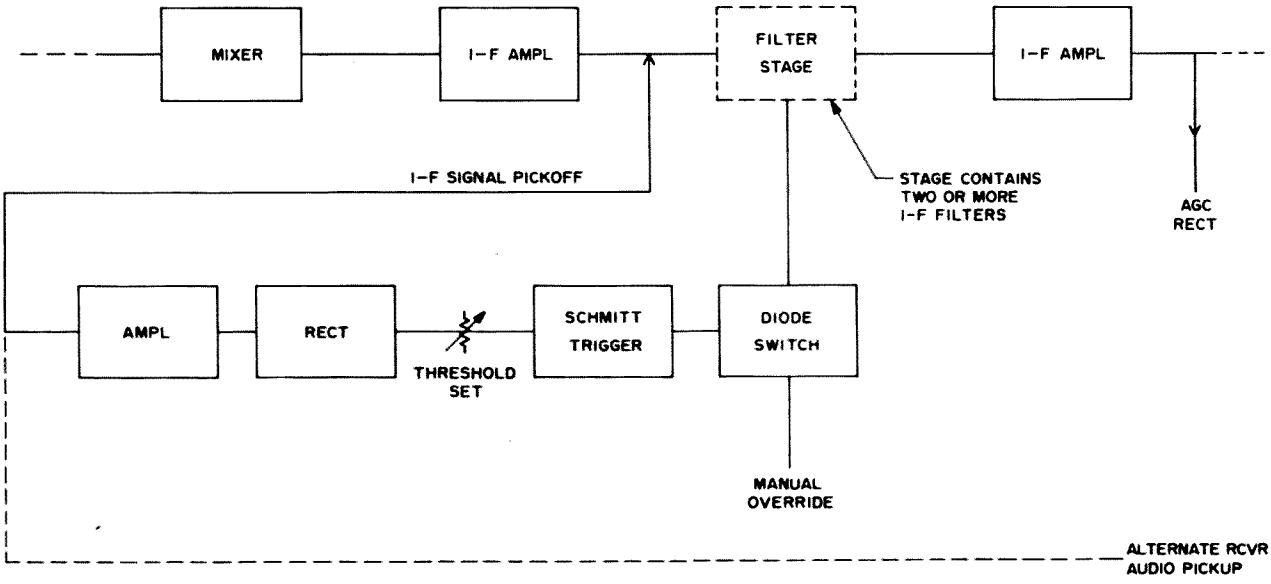

Fig. 1. Basic block diagram of the auto-bandwidth unit. Filter stage is inserted between i-f stages in a receiver. Diode switch as activated by level of i-f signal causes different i-f filters to be used.

filter stage will control agc action. However, the unit can be used in this manner and the control pickup signal can even be the audio output signal.

The unit operates simply on the basis that any i-f signal of sufficient amplitude which exceeds a preset threshold value will cause the diode switch to be activated and switch in the narrower of the filters in the filter stage. One can devise more elaborate triggering schemes where a stage samples and integrates the signal levels in the i-f passband to determine when the QRM level has reached a level requiring a narrower i-f filter, but the circuit complexity involved produces little in the way of better performance. Some provision has to be made so the unit will not be activated by extremely short, high-energy signals appearing in the i-f bandpass – such as a noise pulse – and yet not immediately reset the filter stage to a broader bandwidth after an energizing signal has set it to a narrow bandwidth. If the latter is not done, the unit would tend to follow a high-level CW QRM signal and keep switching the filter stage in accordance with the keying. The necessary discrimination against single pulses and the necessary time delay in filter switching is accomplished by a careful choice of the components in the rectifier stage and by the action of the Schmitt trigger stage. It is in the selection of these components and the action of the Schmitt trigger stage which mainly makes the unit described different from a simple VOX unit where such a unit is activated by receiver instead of transmitter audio and the VOX relay controls the selection of two different i-f filters. However, one can, by experimenting with the circuit time constants, adapt many VOX units for use as receiver audio-activated automatic i-f bandwidth selectors.

Practical Circuit

Figure 2 shows the actual circuit of the selector unit. Discrete transistor stages could be utilized but the use of the readily available and inexpensive Fairchild μL 914s simplifies the circuitry and is actually less expensive than using all discrete components. The first μL 914 unit serves as an amplifier stage and has a frequency response that extends from the low audio frequencies to about 1 MHz. The stage, therefore, does not have to be modified whether the pickoff point to trigger the selector unit is taken at some point in the i-f chain of a receiver or at the audio output of the receiver.

The second μL 914 units is wired as a Schmitt trigger. Normally, the output (terminal 6) of this stage is at nearly ground potential. When about 1.5V input is applied (terminal 1), the output rises to almost the supply voltage potential (+4.5V). The output remains at this level until the input voltage drops to around 1.1V, at which time

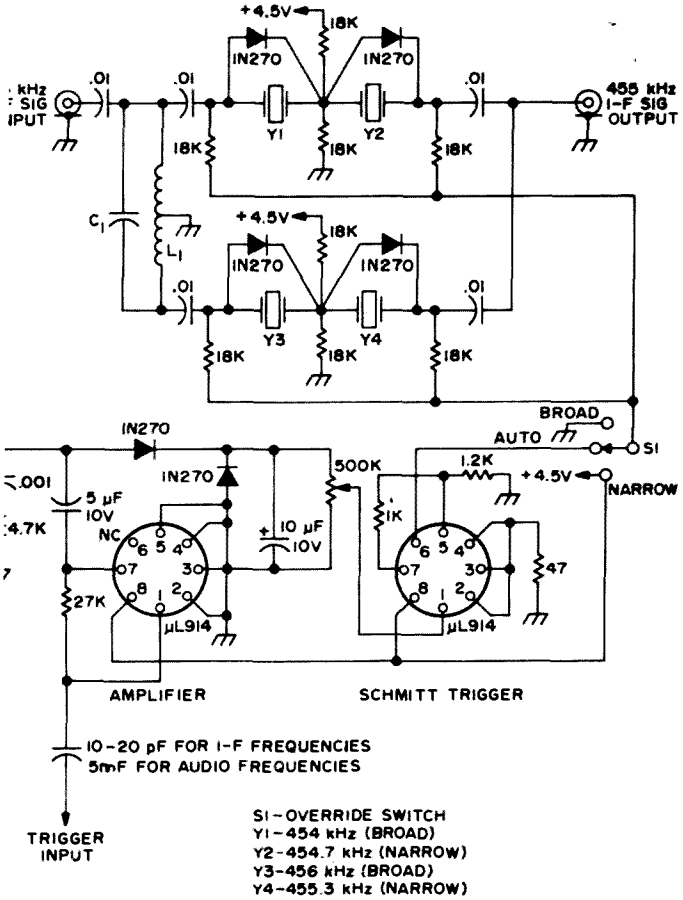

Fig. 2. Circuit diagram of the auto-bandwidth unit. The trigger input can be af or an i-f frequency up to about 1 MHz. C_1 L_1 are chosen to resonate at the i-f frequency being used. Crystal frequency spacing is chosen on basis of bandwidth desired.

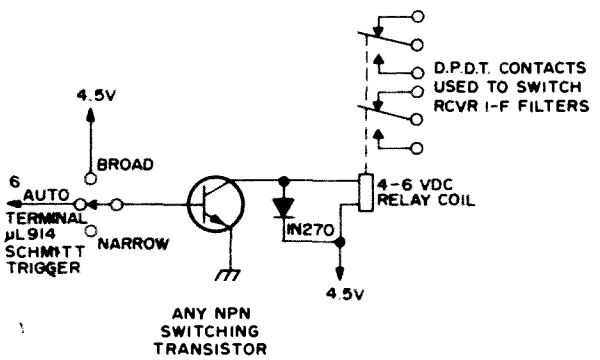
the output again returns to about ground potential. This "hold" action on the part of the Schmitt trigger, plus the characteristics of the rectifier circuit between the two µL 914 units gives the unit the delay characteristics previously described as necessary. The output of the Schmitt trigger drives a diode switch arrangement across a crystal filter circuit. Although the diode arrangement tends to make the circuit look somewhat confusing, the crystal filter circuit is a completely standard two-crystal circuit. The circuit is centered on an i-f of 455 kHz. The 454 kHz and 456 kHz crystals provide a bandwidth of about 2 kHz, while the 454.7 and 455.3 kHz crystals provide a bandwidth of about 600 Hz. Any other bandwidth can be chosen by proper spacing of the crystal frequencies, as well as any other i-f by choosing L and C to resonate at the i-f. When the output of the Schmitt trigger is at ground potential, the diodes across the 454.7 and 455.3 kHz crystals are forward-biased, and these crystals are effectively short-circuited. The diodes across the "broad" bandwidth crystals are back-biased and these crystals control the i-f bandwidth.

When the Schmitt trigger is active, the opposite condition takes place. The output of the trigger stage causes the diodes across the "broad" bandwidth crystals to be forward-biased and those across the "narrow" bandwidth crystals to be back-biased. The switching action is very fast and noiseless. Assuming that an existing i-f strip has sufficient reserve gain to compensate for the loss in the crystal filter circuit, as most receiver i-f strips will, the circuit of Fig. 2 can be used to build an outboard accessory unit for use with almost any receiver or transceiver. In those cases where a receiver already has built in several i-f filters which it is desired to utilize, the circuit of Fig. 2 can still be used and the diode switching arrangement shown applied to the built-in filters.

If the diode switching scheme is not easily adapted to the filters, the µL 914 Schmitt trigger stage can be used to drive a switching transistor which in turn activates a relay to switch the i-f filters, as shown in Fig. 3. The basic scheme shown can be expanded to several more stages of progressive selectivity by using more Schmitt trigger stages, each with a separate threshold control to trigger in turn as the output level of the first µL 914 amplifier stage increases.

Construction and Adjustment

The unit can be assembled either as an outboard accessory unit, or internally in a



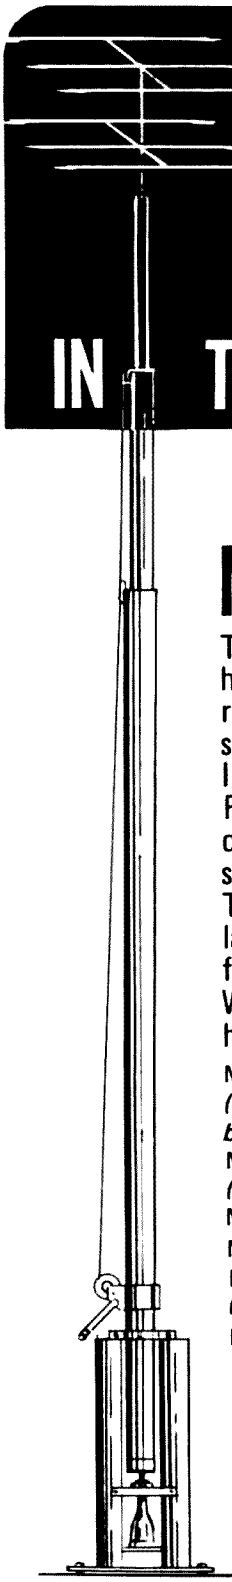


Fig. 3. Instead of using diode switching and an external crystal filter, the two µL 914 stages of Fig. 2 can be used to control a relay for switching the interal i-f filters in a receiver.

A SPACE AGE CONCEPT IN TOWER DESIGN

...TRISTAO'S MAGNA MAST

The new Magna Mast is a heavy duty self supporting, rotating crank-up mast designed for ease of installation. It utilizes the new Tristao Rotor Base with swing over design, permitting antenna servicing at ground level. The Magna Mast's clean tubular design will support 12 sq. ft. of antenna in 60 MPH Winds. Its finish is entirely hot-dipped galvanized.

MA-490 49' Magna Mast *(With wall bracket, flat base & 8' mast)*	$324.95
MARB-40 Rotorbase *(Rotor not included)*	$204.95
MAF-40 Raising fixture	$ 94.95
MA-660 66' Magna Mast	$885.95
MARB-66 Rotorbase *(Rotor not included)*	$379.95
MAF-60 Raising fixture	$109.95

If your requirement is for a tower of only 35 feet, let us send you specifications and prices on Tristao's "Mini Mast". It's a little beauty.

Substantial savings available on complete antenna packages. Please write for free literature.

Butler, Missouri 64730 816/679-3127

receiver. The latter type of placement is most convenient when utilizing the i-f filters built into a receiver. There is nothing critical about the construction of the unit except the usual precautions of lead dress, etc., appropriate to the i-f being used. The threshold control has to be available as a panel control since it requires manual adjustment depending upon band conditions and depending upon the setting of the rf and/or i-f gain controls in a receiver (also depending upon the af gain control setting if the receiver audio output is used to trigger the unit). With some practice, the threshold control can be set so that the unit is activated when the QRM level just exceeds that of a signal being copied.

Results

Several experiments were tried using the unit of Fig. 2 for CW reception with a 455 kHz i-f receiver. Triggering the unit from the first i-f stage output in the manner shown in Fig. 1 produced the best results. However, audio triggering was also quite effective as long as the agc circuit in the receiver was disabled. The main value of the unit was in moderate to heavy QRM situations, where very strong signals were apt to suddenly appear while a relatively weak station was being copied.

The use of the unit did not completely guarantee continued reception of the weaker signal because of other factors being involved such as receiver overload, agc capture, etc. However, the unit reacted to the QRM situation almost instantaneously as compared to the time required to manually readjust the i-f selectivity. Some further refinement of the unit is certainly indicated. The constant readjustment of the threshold control might be eliminated by linking the "base" level for this control with the level on the bias line in the receiver as controlled by the rf gain control. Nonetheless, the unit did demonstrate the real advantage of an auto-bandwidth feature for use in receivers under today's heavy and suddenly changing QRM conditions. With some added refinements, such a unit should prove to be as useful as such accepted receiver features as avc/agc, automatic noise limiters, etc.

"Break"

". . . so I told him where to get off the expressway and I guess he's all right now, Steve. Well, it's getting late, about 11:30, so I guess I'll knock off and go to bed. Been good talkin' to you. WB1ABC, this is W1XYZ." ssshhhkchunk

"Right, Bill. That guy'll be OK as long as he doesn't go too fast. It's a bit slippery out there and driving is kind of poor. I got in only a little while ago and it seemed like it was going to get colder and freeze up all of this snow that's lying all over the place. When you come right down to it, it's really not too good out there at all, but as I say, if he takes it easy, he'll be OK. Say, before you go, can you tell me what's going to happen at the meeting Friday? Break." shshshk "Break"shshkchunk

"OK, stand by, breaker. Steve, the meeting is going to be held at Les's house instead of at Mike and Laura's like it was planned. Seems like their little daughter caught the flu. We're gonna see a slide show about the new repeater down in, oh, what's the name of that city in Rhode Island? You know what I mean, Steve? Break." shshshsk "Break"shshsshkchunk

"Breaker stand by please. Yeah, it's in the Bay area. I forget the city you mean, but I know what you're talking about. Go." shsh"Br –

"Right. Didn't want to let the tail drop. No sense wearing out the relay. Well, the pictures will be about that new machine they're setting up. It should be a good one. Say, I'm bringing my wife. Why don't you bring yours? All the gals can head off to the kitchen while we take in the show. They never want to see any of this radio stuff. What say?" shshs"Break"shshskchunk

"OK. Just a minute, breaker. Good idea, Bill. I'll let her know what's happening. I know she'll want to see the others. Hey, here's an idea. Why not have all the wives

bring a little home brew something. Since Les and the missus are being caught by surprise, we all can help out with the goodies." shshsshsh –

"That's a good one. I'll tell the little woman." shshsh –

"First thing tomorrow morning I'll get in touch with Joe and Mel and have them each call a few of the guys and we can get the wives working on this right off. We can make a real party out of this. I'll even volunteer to leave for a while and get some pizza if anyone wants some. If we get ahold of the Sokittoommee VHFers, we could make a hamfest out of this." shshsh"Break"shshsh skchunk

"Yeah, and what about this kids?" shshs –

"No problem. The high school is on vacation now so there should be a lot of baby-sitters available. Even on short notice. It's a natural. shshshshkchunk

"All right then. It's settled. I'll call up the host and hostess. Boy! Will they be surprised. It's a good thing they have a large house. Some coincidence, eh?" shshs –

"This is great. But what about the weather? It looks like it might start coming down and the weatherman says there's a pretty good chance of more of the white stuff and some icing over." shshsh –

"Well, there are a few hardy souls with four wheel drive cars. If it's not too bad, they might be willing to make the rounds and pick everyone up. There are only ten of our guys and six of the 'toommees and everyone is pretty close together anyhow." shshshskchunk

"I dunno. It could be pretty slippery, even for a four wheel drive. I'm not so sure any more that it's a good idea. Like, the slides will be good. That's a fact, but if it's snowing, the high schoolers won't be able to get out for the most part and most of us are parents and won't go out ourselves either. on a rotten night, it seems like that's the only time a family gets together. If it were really bad, I'd like to stay in with my family. Wait a minute . . . I'm listening to a weather report . . . high winds . . . slippery driving . . . rain, later turning to snow and sleet . . . low fog . . . Wow, it sounds pretty rotten right now. I wonder about tomorrow, Bill." shshsh"Break"shshkchunk

"Hang on, breaker. Y'know, Steve, maybe it was a lousy idea after all." shshs –

"No, Bill. It's just that the weather is so poor and driving is unpredictable. That's all. It's a good idea. It's just that the timing is off. Maybe for the next meeting we can all get together. Hey, I just got another idea. How about the two clubs setting up a joint repeater. Whadoyou think of that?" shshshkchunk

"I like that idea. What with two sets of brains in this town, we should get together to do something like that. I've been foying with the idea of putting one up myself." shshs –

"No. Go on, you couldn't do it and you know it." shsh –

"Really. I've even collected all the parts for one. I just gotta lash them all together." shshsh –

"You're fooling." shshsh –

"It's true. You can come over any time and see it all." shshshs –

"I still don't believe you." shshshkchunk

"Well, the proof is in the pudding. Speaking of pudding, that's what it looks like out there right now, and that's what I'll look like inside if I don't get some sleep. Say, whatever happened to that breaker. C'mon ahead breaker." shshshskchunk

"Yeah, c'mon ahead breaker." shshshskchunk

"Breaker, speak now or forever hold your peace." shshshkchunk

"One last chance." shshshshkchunk

"Steve, you don't suppose there was an accident, do you" shshshshshkchunk

"No, I doubt it. The guy sounded OK when he spoke. I don't think anything is wrong." shshshshkchunk

"But he tried to break in so many times" shshsh –

"Look. He would have said something if something was wrong. Wouldn't he have?" shshshkchunk

"Yeah. I guess you're right. Well, see you at the meeting." shshshshskchunk

"Right. This is W1XYZ clearing with WB1ABC at twelve-thirty on a mucky night. G'night." shshsh –

"G'night." shshshshskchunk

THE CASE FOR TONE ACCESS

Tone access is the best way to protect repeater inputs when two or more repeaters share a common input frequency. In many cases the coverage of the repeaters overlap each other and a mobile trying to access one may bring up several others too. This situation is highly undesirable as well as annoying to the monitors of the other repeaters, particularly if they have automatic logging. Tone access can be effective in eliminating these unwanted key ups and is used in three different modes: Continuous Tone Coded Squelch (CTCS), Tone Burst, and the "Whistle-Up."

Of all the tone access systems CTCS is the most positive as it will even work when the input signal to the receiver is quite noisy. In a CTCS system a small encoder is mounted in the mobile of base transmitter and supplies a subaudible tone in the range of 80 to 180 Hz to the audio input of the transmitter. Each time the CTCS equipped are placed on the air the CTCS tone is continuously transmitted at a level that is about 20% of the maximum speech deviation. In a typical narrowband system where the maximum speech deviation is ±5 kHz the CTCS deviation level is adjusted between ±750 Hz to 1 kHz. The repeater input receiver in turn is fitted with a CTCS decoder and this is used to control the repeater transmitter in place of the usual Carrier Operated Relay (COR). Thus the repeater can only be brought up by an input signal having the proper CTCS tone frequency, and when this signal goes off the air the repeater will drop out even though there is another signal on its input frequency. It is the CTCS tone that not only brings the repeater up but also holds it up and when there is no CTCS tone the decoder cuts the keying voltage off to the transmitter. (Of course there is normally a few seconds drop out time but the repeater does drop as this type of control is very positive. A CTCS system is fairly secure as the decoder will only respond to CTCS signals that are within ±1 Hz of the CTCS decoder frequency.) CTCS is widely used in Motorola calls their system "Private Line" or P.L., and General Electric calls theirs "ChannelGuard" or C.G. For those amateurs having commercial rigs the installation of a CTCS encoder is only a matter of wiring up the manufacturer's encoder in the unit. But for the ham who has an imported unit or a piece of older commercial gear the installation of a CTCS encoder has posed somewhat of a problem. But recently some small CTCS encoders have become available in the price range of $15–$25. These types of encoders use resonant reeds as the frequency determining device and you can figure on spending an additional $18.50 for the required reed.

Avcom[1] has also come out with a new small CTCS encoder that is quite different than the rest in the fact that it does not use a reed but a low frequency crystal instead. The crystal gives as good as or better than the necessary ±1 Hz stability and its cost is less than one third of the cost of the reed. Avcom calls their little CTCS encoder a PL100 and it is all solid state using both transistors and digital IC's. Its dimensions are 1.5 x 6.2 x 4.4 cm (0.6 x 2.4 x 1.75 in. [H x W x D]). The PL100 utilizes a crystal controlled multivibrator whose output is fed to three IC decade dividers to obtain the desired CTCS tone frequency. The output of the last decade divider is fed to a two section low pass filter to obtain a sine output. Suppose you want a CTCS frequency of 110.9 Hz (a standard CTCS channel frequency) – you would simply use a 1109 kHz crystal since the encoder divides its frequency by 1000. The PL100 also has a built-in voltage regulator since the logic requires 5 volts. The encoder will operate over 11 to 15V dc input and has adjustable high and low impedance outputs. The crystals for the PL100 are available from JAN Crystals[2] at $4 (per crystal) for 100 Hz and $6 for the proper crystal for any other CTCS tone. The Avcom PL100 is available in three forms: a PC board, parts list, schematic and pictorial for $6; a complete kit for $17.95; and the completely assembled unit for $24.95. All three forms require the addition of a crystal that is the desired CTCS tone frequency times 1000.

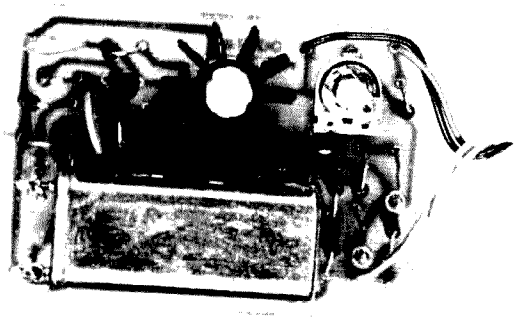

Fig. 1. Avcom PL-100 CTCS encoder

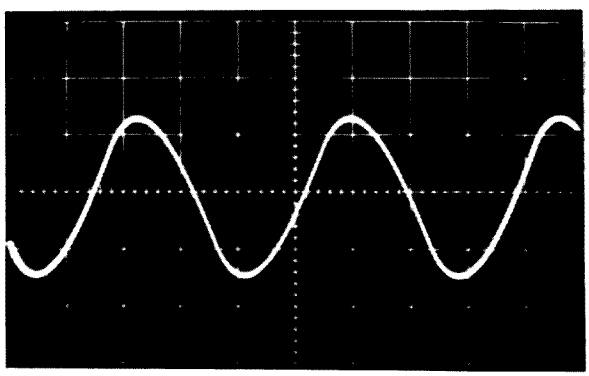

Fig. 2. Output waveform of Avcom PL100.

Tone burst access is the second form of tone access systems and is the simplest way to go as the frequency tolerances are not as critical as those of the CTCS system. Tone burst also allows a multichannel or multitone encoder that can be used on many repeater systems. A tone burst encoder is simply an audio oscillator whose output duration is controlled by a timing circuit. The timing circuit can be triggered by the grounding of the transmitter push-to-talk (PTT) lead or by the application of +12V dc to the encoder. Most tone burst encoders use the PTT type of keying that grounds a lead from the encoder when the mike button is pushed. Normally the tone burst duration is set at 500 ms. Some tone burst encoders have as many as six tone frequencies which is more than adequate. This allows the user to access a number of repeaters that have common input-output frequencies but different tone burst frequencies. The tone burst begins as soon as the operator pushes his mike button and lasts for a half second. This happens automatically each time the operator begins a transmission. However the operator must now remember to pause for a half second before beginning to talk thus giving the tone burst time to complete. If the operator were to speak during the tone burst the speech would interfere with the tone and the decoder at the repeater may be confused at the complex wave form and the repeater may not come up. The tone burst deviation is normally set to be 60% of the maximum speech deviation. A tone burst access repeater requires a tone burst decoder at the receiver site in addition to the COR. Both must give positive outputs before the repeater will come up on the air. The tone

[1] Avcom, P.O. Box 29153, Columbus OH 43229.

[2] JAN Crystals, 2400 Crystal Drive, Fort Myers FL 33901.

burst access system has one minor drawback – if there is another signal present at the repeater input after the initial tone up station goes off the air, the repeater will stay up until the three minute time-out time drops it out. Normally the tone burst decoder is reset by the COR dropping or by the time out timer activating. The tone burst decoder also resets the time out timer each time a tone burst is received.

Most tone burst encoders use an LC type of audio oscillator that has excellent frequency stability but requires precision capacitors or padding capacitors to set the oscillator exactly one frequency. Other tone burst encoders use RC oscillators, integrator oscillators, and Voltage Controlled Oscillators (VCO). All of these last three types have an advantage that the tone frequency may be set by the use of pots thus allowing the user to have a number of pots and a selector switch to select various tone frequencies. Each pot can adjust the oscillator over a range of about 1400–2600 Hz. These types of encoders are easily set to frequency by the use of a frequency counter and a screwdriver, and shorting the burst timing capacitor.

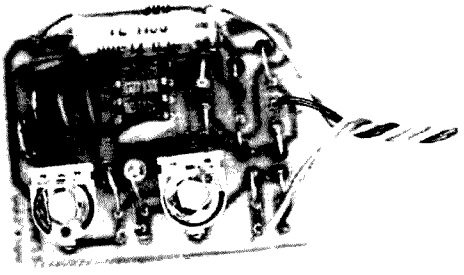

Fig. 3. Avcom TN421 tone burst encoder

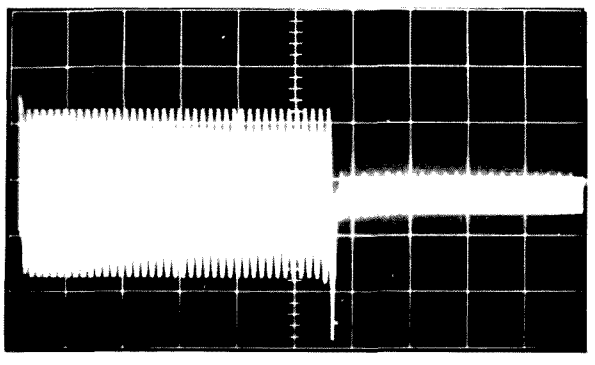

Fig. 4. Burst envelope of Avcom TN421. Horiz. = 100 MS/cm. Note: Extra ripple was due to stray ac pickup in test gear.

The Avcom TN421 is an integrator oscillator type of tone burst encoder using only one IC and an RC burst timing network. It is so small that it can be mounted in the Drake TR-22 with ease. The TN421 is only 1.5 x 4.5 x 3.8 cm (0.6 x 1.8 x 1.5 in. [H x W x D]). It only requires the connection of three wires to hook to a transceiver: +12V dc, audio to the mike input, and a wire to the PTT connection. The TN421 has a frequency range of 1400–2600 Hz and has adjustable high and low impedance outputs provided. It has a nominal 600 ms tone burst. The TN421 is available from Avcom all built and ready to go for only $19.95. It will also fit in a commercial rig control head.

The third type of tone access system is the whistle-up which is a form of the tone burst except that the frequencies used are between 1500 and 1800 Hz. The decoders are about 100 Hz wide as are the ones for the normal tone burst frequencies. Due to the lower frequencies the average ham can whistle the proper tone and bring up the repeater. There are many different types of CTCS and tone burst decoders. Most commercial and ham decoders use resonant reeds for the CTCS and LC circuits for the tone burst frequencies.

A new type of tone decoder is appearing on the horizon in the form of a Phase Locked Loop tone decoder. One such device is the Signetic NE-567 and will work with a –6 dB signal plus noise-to-noise ratio. This gives very impressive performance. Its tone decoding frequency may be set by use of a pot and a frequency counter. There is no input signal required to adjust the NE-567 as all that is necessary to do is to monitor the VCO frequency with a counter to set the decode frequency. The bandwidth may be set from a few hundred Hz to about 10 Hz depending on your needs. It has a frequency range from a few Hz to several hundred kHz.

So if your carrier access repeater is being bothered with unwanted key ups from other systems and/or if you are being bothered with intermod or stray signals, tone access is the answer. The equipment is available now so you *can* do something about it rather than gripe about it. It's not complicated nor expensive and it is a solution that works.

CUSTOMIZED AFSK-MCW & CODE PRACTICE OSCILLATOR

The complete AFSK-MCW, and code practice oscillator using an IC circuit is built into a standard 4x2¼x2¼ in. minibox. A printed circuit board is used, and careful placement of parts is necessary in order to get all the parts into the box.

Obtain one jack and a plug like the one on the transmitter to be used. Mount the jack on one end of the box, and bring the plug out the other end using shielded cable. Mount all components in the box. It would be a good idea to tune the coil and check its operation first. So, with the switch in one position, normal mike control can be used. With the switch in the other position you can key the transmitter, and insert AFSK-, or MCW at the mike input, and at the same time cut off the speaker. Any combination of switching arrangements can be used to suit your particular needs. Even a small relay could be used.

To use as a code practice oscillator, no connections to the transmitter are necessary. Plug a speaker into the speaker jack (voice coil is not critical). Plug a key into the key jack. You can use either the 2125 Hz tone, or break the connection at the keyboard connection, and use the 2975 Hz tone.

Sw#1 is a 3 pole double throw switch to fit your need, and Sw2 is part of the mike control system.

Parts other than C1, C2, and C3 are not critical. These should be mylar capacitors. Do not use ceramic or disc capacitors since these tend to cause drift.

Tuning of L1 can be done by varying the capacity of C1 and C3, or taking turns off of L1. For best results you should be very close to frequency. With the keyboard jack closed you should have a 2125 Hz tone; with it open you should have a 2975 Hz tone. In some cases a polar relay, a high speed relay, may be necessary across the printer contacts to key the oscillator.

USING THE LM 373

About 2 years ago a new integrated circuit was announced by National Semiconductor and was labeled the LM373. Inside the little TO5 can were the makings of 4 gain stages, an agc section, a balanced mixer and a peak detector. At least that's what the poop sheet said, and circuits were shown for using the little jewel in various types of i-f strips. I was fortunate at that time to acquire an LM373 and promptly breadboarded an SSB i-f strip to see how it would perform. It performed amazingly well and I was sufficiently impressed to start planning a receiver designed around this new IC.

Although I didn't know it at the time, all the ingredients for a classic demonstration of Edsel Murphy's Law were gathering for the final curtain. The clincher came when word got around that the manufacturer had thrown in the towel. That's when Murphy struck and left me with a crisply burned collector's item.

Now, 2 years later, I once again own an LM373 and have been assured by the company rep that these items are here for keeps and are available from distributors.

The present LM373 is basically the same as its predecessor, including pin connections, although internal circuitry is somewhat changed. The device will perform many diverse functions which make it adaptable to AM, FM, or SSB i-f systems by merely changing a few connections. In the application described here, the IC is used in a receiver capable of operating in either AM or SSB modes. It was made small only because my hangup is miniaturization. It is designed to cover 3.5 to 4.0 MHz and an all-band converter will someday be used ahead of this "tuneable" i-f. If the cabinet had been about an inch larger, I might have gone all the way right from the beginning.

Let's take a look at this new device and see how it may be used to perform the functions of particular interest to the ham. Figure 1 shows how the various sections of the circuitry are tied together internally and which points are brought out to pin connections. Note that the IC is divided into 2 separate areas having no common internal signal path. The upper portion, consisting of 2 gain stages and the agc section, is externally coupled to the remaining circuitry by the main selectivity determining device. This usually consists of a mechanical, ceramic, crystal or LC filter operating in the 50 kHz to 15 MHz frequency range.

In order to better understand just how the various sections of the LM373 can be made to perform the desired functions, let's look at some block diagrams. Figure 2 shows

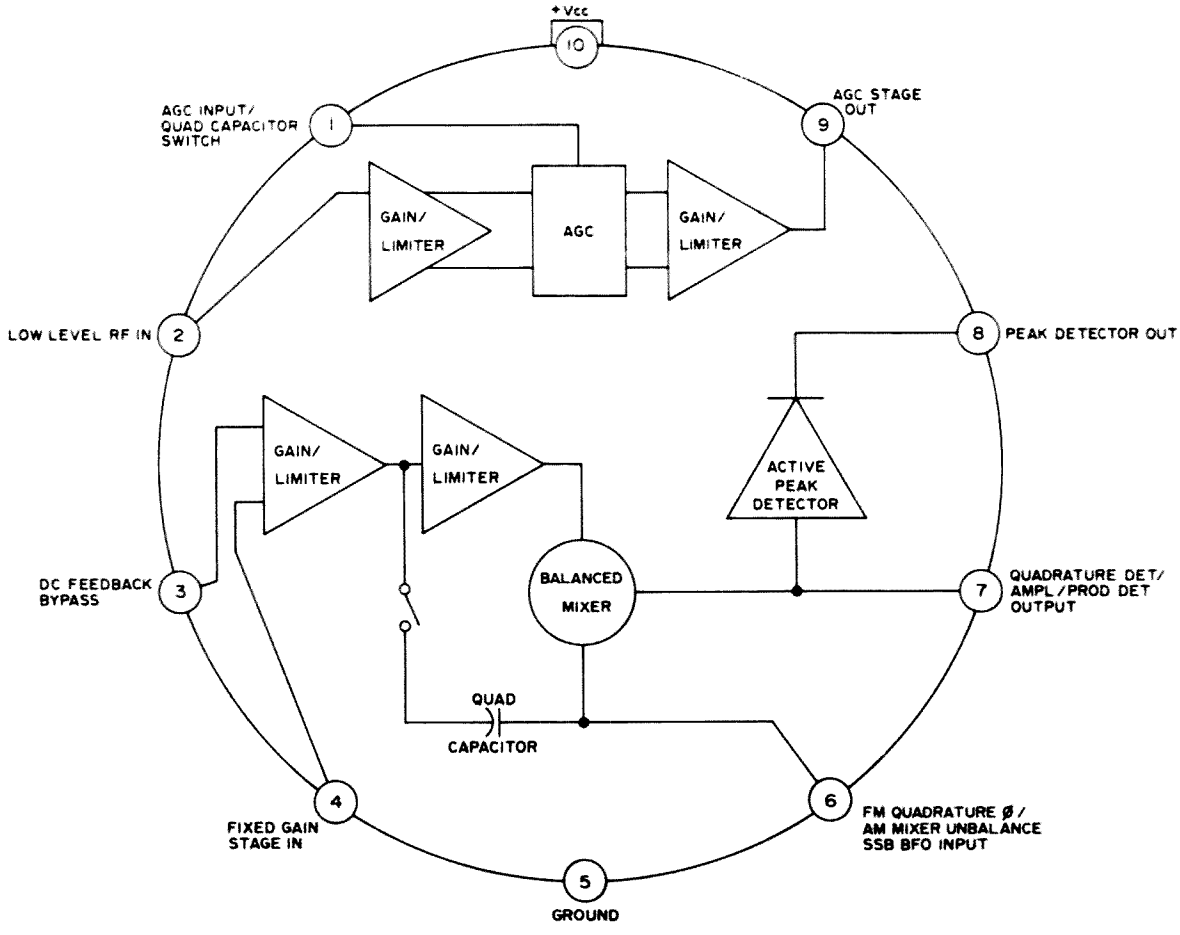

Fig. 1. Pin connections and internal wiring of theLM 373.

the connections used for operating in the AM mode. In order to disable the balanced mixer for this mode, an offset voltage is introduced at pin 6 by means of a resistor. Agc voltage is taken from the output of the peak detector and connected to the agc input at pin 1 through an RC network with the desired attack/decay characteristic. An agc range of 70 dB with operation down to 50 μV rms input is possible with this circuit.

For SSB/CW operation, refer to the block diagram of Fig. 3. A bfo signal of 25 mV rms or greater is fed into the balanced mixer at pin 6, causing the mixer to act as a product

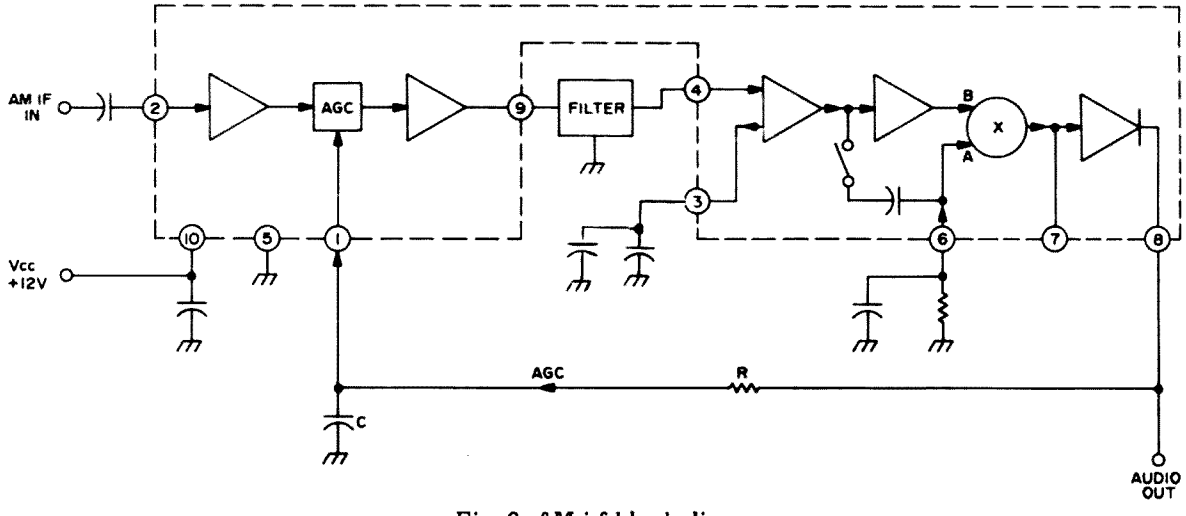

Fig. 2. AM i-f block diagram.

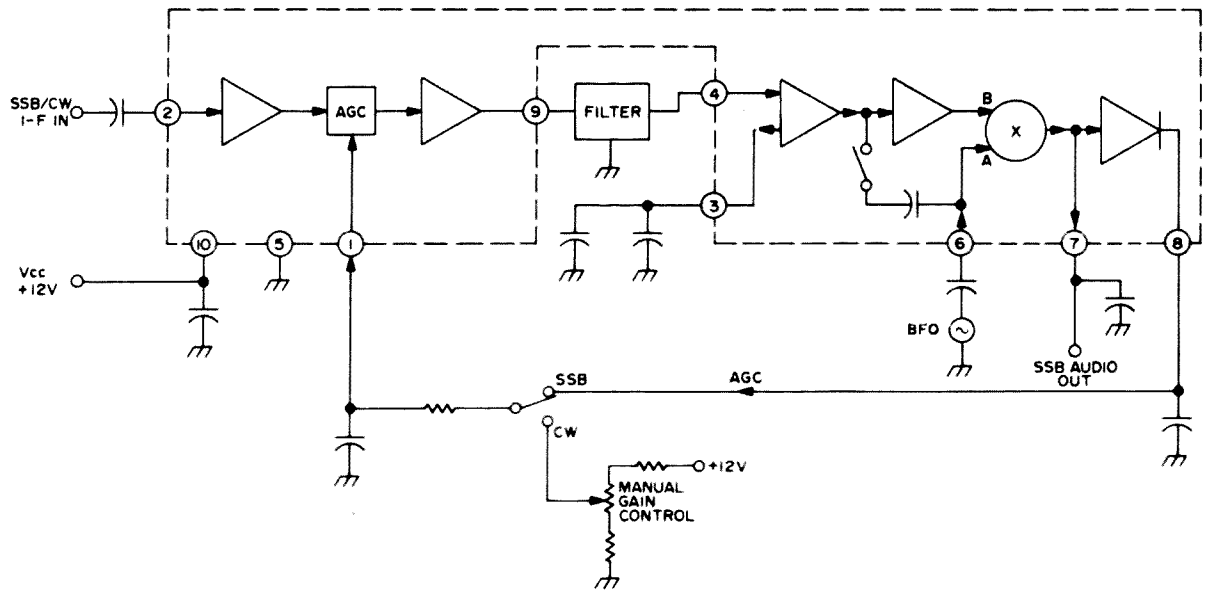

Fig. 3. SSB/CW i-f block diagram.

detector. The peak detector generates an agc voltage derived from the audio fed to it from the product detector. This voltage is fed back to the agc section through the RC network. A means of providing manual gain control for CW operation is also shown in the block diagram. So here we have an i-f amplifier, a fast attack, slow release audio derived agc system and a double-balanced product detector all in one neat package.

Although I have not tried the LM373 in an FM receiver, some readers may be interested in this type of operation and Fig. 4 is the block diagram for an FM i-f system. By grounding pin 1, the agc is defeated and all gain stages become symmetrical non-saturating limiters. This action also connects an internal quadrature capacitor to pin 6 which is also input A of the quadrature detector. An LC network tuned to the nominal i-f frequency is connected externally to pin 6. This network produces a frequency-dependent phase shift with respect to the signal at input B of the quadrature detector. A pulse duration modulated output is produced by the detector and integrated by the capacitor connected to pin 7. The Q of the quadrature network will influence both the output level and the distortion. For a given deviation, increasing Q will increase both output and distortion. At least a 50 mV rms signal is required at pin 6 to ensure switching action of the detector and maximum output. Audio at a higher level may be taken from the output of the peak detector at pin 8.

In addition to the applications above, this versatile IC may be used in several other interesting circuits. These include SSB generator with alc, constant amplitude/amplitude modulated rf oscillator, first i-f amplifier/

DATA ENGINEERING INC.
Box 1245 · Springfield, Va. 22151

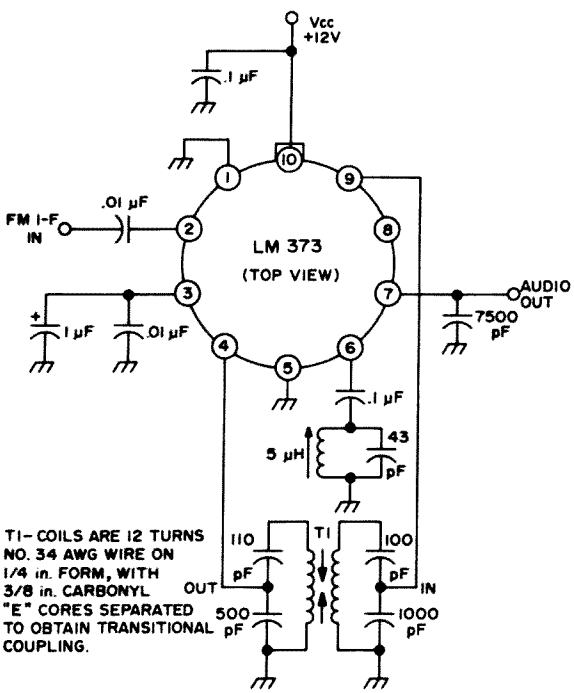

Fig. 7. FM i-f strip wiring diagram shown with transformer interstage coupling.

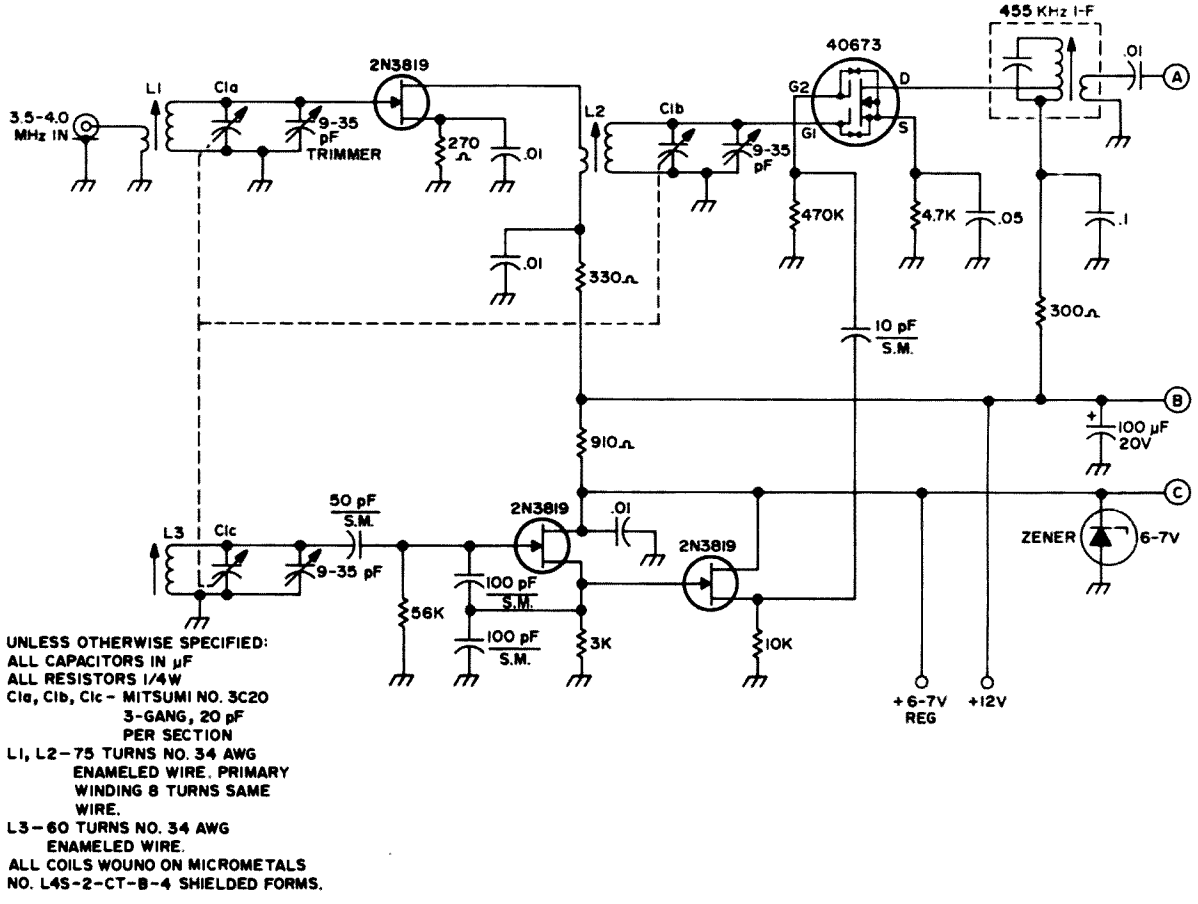
inductance high frequency capacitor and a larger tantalum for the low frequencies. You should also observe the usual rules of good layout practice and keep leads short when working with high gain circuits such as this.

Figure 8 is a schematic for the front end of the receiver I built using the LM373 in the i-f system. The rf and hf oscillator stages both use an inexpensive 2N3819 plastic junction FET. The mixer uses a dual gate MOSFET. Another 2N3819 is used as a source follower to isolate the hf oscillator and prevent pulling. A small transistor type i-f transformer couples the mixer to the LM373.

Figure 9 is a schematic for the remainder of the receiver; including the i-f, bfo and audio portions. In order to operate the i-f system in both AM and SSB modes, it was necessary to incorporate a 5-pole, 3-position switch, S1, to make the transfer. Two of the poles are used to switch the agc time constant components from AM to SSB. Another pole provides bfo input to pin 6 for SSB operation or an offset voltage for AM. Pole number 4 selects audio output from pin 7 for SSB or pin 8 for AM. The final section applies voltage to the bfo for SSB/CW reception. S2 is a small SPDT toggle switch



used to go from manual gain control to normal agc when in the SSB/CW mode. The manual gain control is useful when listening to CW.

A second i-f transformer is used for the bfo tank and is tuned by a dc voltage applied across a capacitor diode. I used a V47 but many ordinary silicon diodes will work satisfactorily in this application. Epoxy rectifiers are also a good bet. Depending on the frequency variation obtained, the 27 pF series capacitor may have to be altered for proper tuning range. If range is insufficient, increase the value of the series capacitor. If bfo range is greater than needed, a smaller capacitor may be used.

Operating voltage for the hf oscillator, the bfo and its tuning diode is regulated by a zener diode. Almost any small zener in the region of 6 to 7V may be used. The base/emitter junction of a silicon transistor makes an excellent zener and no doubt several can be found with 6 to 7V breakdowns. With these critical circuits regulated, the main supply can be varied from 9 to 15V without producing any noticeable change in the received signal other than audio output. A 2N3819 source follower further stabilizes the bfo.

Because I wished to keep size to a minimum, I used a tiny 455 kHz ceramic ladder filter as the interstage coupling device for the LM373. This filter, the Murata CFS-455J, has a 3 dB bandwidth of 3 kHz and is adequate for general use. I used a printed circuit board for assembling the receiver and arranged it to take either the ladder filter or a Murata SFD-455B dual section filter. This provides about 4.5 kHz bandwidth at 3 dB. Because this is not a construction article in the strictest sense, and because some of the components dictated board layout not compatible with most junkboxes, a printed circuit layout has not been included.

I incorporated an audio preamp since I like to have a little reserve when it is needed. This stage can use almost any NPN audio transistor and is not at all critical. The transistor I used was an unmarked refugee

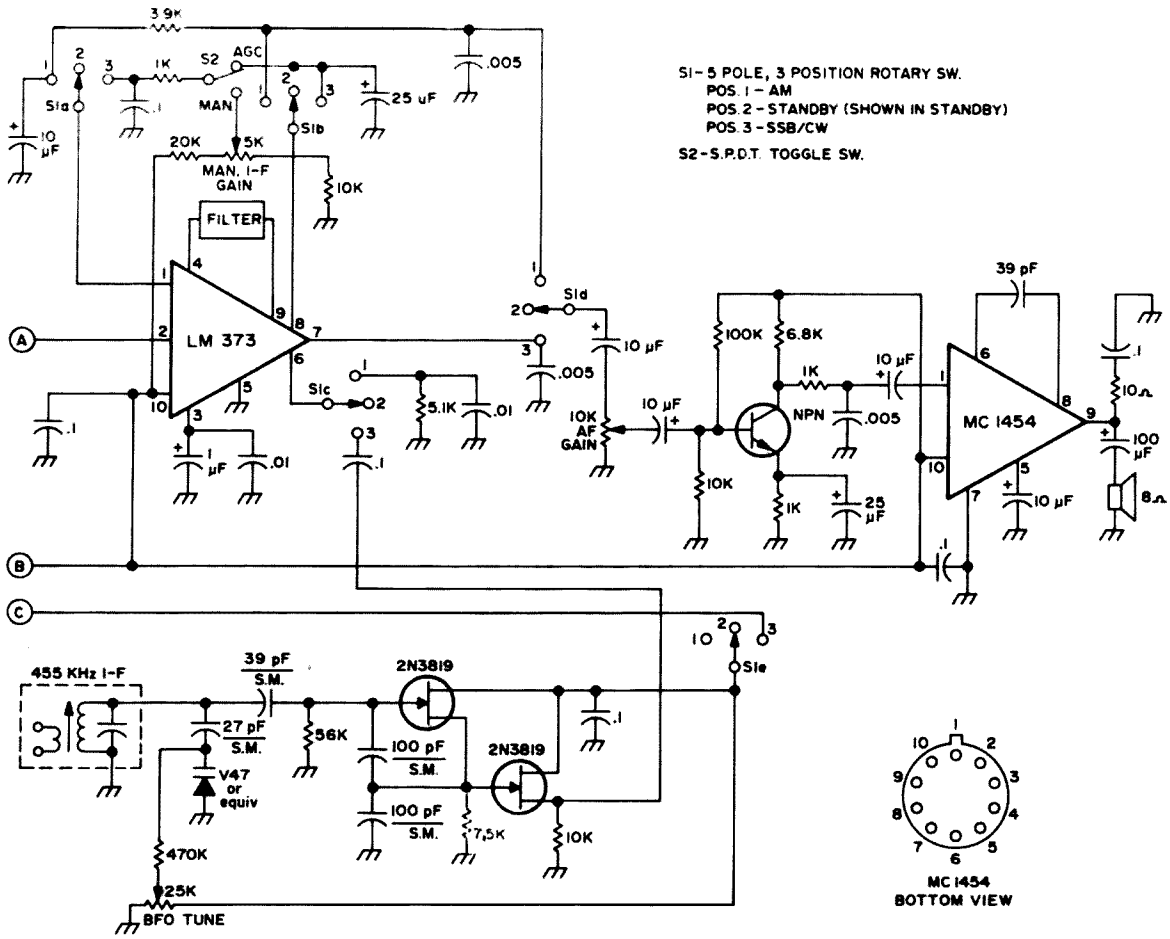

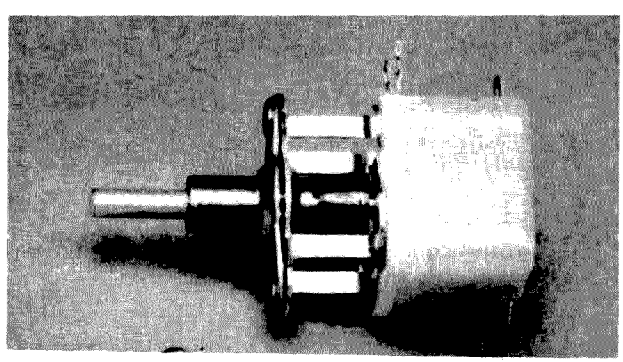

Fig. 9. Schematic of the bfo, i-f and audio portions of K4DHC's receiver.

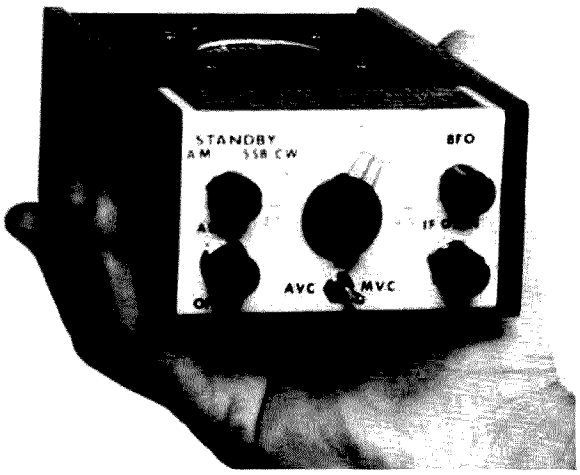
from my junkbox. A Motorola MC1454 IC power amplifier is used in the audio output stage. It is capable of 1W of audio into an 8Ω load. I've had excellent results with this IC and have used it in many projects. The small speaker built into the receiver doesn't do the audio justice, but does make the receiver self-contained.

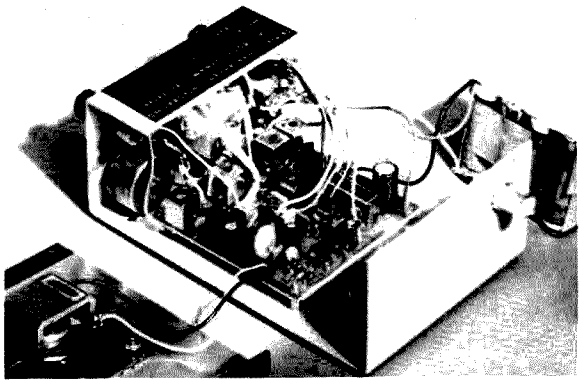
At present a block of 8 pen cells soldered in series powers the receiver. No-signal current drain is about 28 mA, rising to 40 or 50 mA on audio peaks at normal room level. At these levels it is not necessary to heatsink the audio amplifier.

Construction of the receiver is unorthodox in some respects because of my desire to keep it small. Since some of the ideas used here may be of interest to others, I'll go over the main points.

The front end tuning capacitor is a tiny 3-gang film dielectric type of 20 pF per section. It is driven by an equally small 4.5:1 ball drive attached directly to the tuning capacitor. Unfortunately, a pointer was not available for this drive but one was fashioned quite easily and can be seen in the photograph. The 3 trimmers, Erie style 538, were mounted on the capacitor and the whole assembly fastened to the front panel along with the other controls. This saved considerable board space and did not add anything to the space required behind the front panel.



The 3-gang miniature tuning capacitor with reduction drive attached. Homemade pointer is push-fit over the large (direct) shaft.



An additional saving was achieved by mounting as many components as possible on the mode selector switch, S1. Since panel area was scarce, I used a small diameter Japanese rotary switch having 3 decks with a total of 9 poles and 3 positions. This is a Lafayette part number 99F61715 which lists for only 79¢. Since it is a shorting type switch, it was necessary to use position 1 and position 3 of each section to avoid shorting circuits during transfer. An unexpected bonus resulted, however, when the middle position worked out fine for "Standby." Since the switch has many more contacts than required, unused lugs made convenient tie points for mounting the associated resistors and capacitors. With these savings, the printed circuit board for the entire receiver ended up being a 3-in. square.

I think that most will agree that the principal limiting factor in shrinking equipment size, is front panel space. Half-inch knobs seem to be the smallest practical size, and even then you need finger room in between controls. The Ten-Tec cabinet I used is the smallest of their JW series. Actual panel space is 2-¼ x 3-5/8 in. As can be seen in the photograph, there isn't much room left over.

If you build up a copy of this receiver and use the specified coil forms, a suggestion may be in order. After alignment is completed, put a small ball of coil wax in the opening of the oscillator coil and melt it down with the tip of a small soldering iron. The bobbins in these coil forms sometimes do not fit tight and cause microphonics or instability in the oscillator output. The wax holds the bobbin tight and prevents any of these problems.

K4DHC's miniature 75 meter receiver utilizing the LM373 in the i-f system.

Interior view of the receiver. The LM373 is just behind the i-f transformer in the middle of the board. The 3 kHz ceramic ladder filter is just to the right. The pen cell battery pack normally sits in the space between the board and back panel of the cabinet.

That covers the basic uses of the LM373 and may have set you to thinking about applying this versatile device to some of your own pet projects. It should be pointed out that the version discussed here is the limited temperature range LM373H in a TO5 can. Price is $4.85 in small quantities. A 14-pin DIP version, the LM373N, was to be made available at slightly lower cost but I hadn't checked on this at the time of writing.

For those who may be interested, I have a limitied supply of the uncommon components used in the receiver. This includes the 3-gang tuning capacitor, the ball reduction drive, Murata filters and shielded coil forms. Drop me a line for information.

Results to date using this i-f system have been quite gratifying. The LM373 provides more than adequate i-f gain at 455 kHz and the agc acts without any noticeable pumping. Overall, the use of this device has drastically cut component count while providing excellent circuit performance.

If you are wondering about the weird nameplate on top of the receiver, it came about because I had to cover some bad scratches and it seemed the only way to do it.

Ken W. Sessions, Jr. K6MVH

REPEATER SITE BREAK-IN ALARM

. . .Lets you hear what the burglar is saying as he robs you blind.

It was very warm in my non-air-conditioned repeater building and I had been working through the most scorching period of the hottest day of the year putting in a new control system. I was tired and dusty and irritable and impatient. I just wanted to get home. So, when it was well past time for supper, I made a batch of temporary alligator-clip connections to keep the repeater operational and went on down the hill. Since I planned to return first thing in the morning, I left all my test equipment and tools at the site.

When tomorrow rolled around, I was still tired. The repeater seemed to be perking right along without any trouble, so I put off making the trek. It wasn't until a week had gone by that the repeater finally crapped out completely and I *had* to visit the site. And when I did, I wished I'd returned the day after my earlier visit. When I unlocked the building and went inside, I was stunned. My test equipment – some of it borrowed – was gone! My tools were gone! The only thing remaining intact was the repeater itself. I had been robbed!

Someone had either jimmied the door or somehow managed to unlock it. My initial

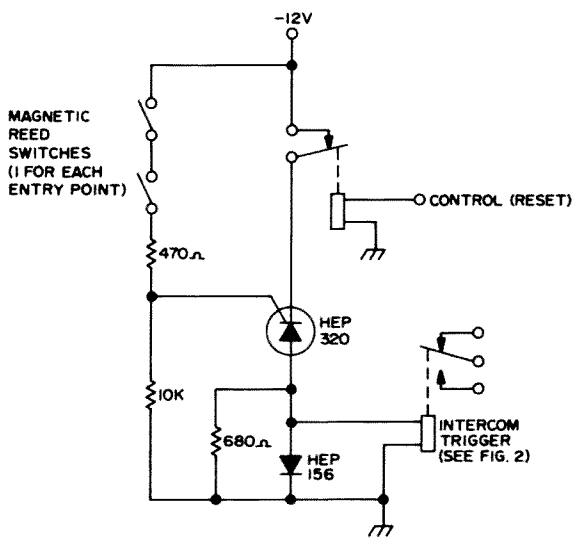

Fig. 1. Basic repeater intercom alarm. After the circuit has been triggered, any short pulse applied to the reset relay will cancel the alarm, resetting the system.

reaction, after that first shock wave, was fury – but not fury at the thief; I was angry with myself! I had a superb automatic communications system up there that could have been used to warn me of an unwelcome intruder. But I had not had the foresight to use it for that purpose. Then and there I made up my mind never to install another repeater without an automatic alerting device to let me know when the site is being "visited." Admittedly, that was like locking the corral after the steers have been rustled, but at least I could be relatively certain of hanging onto the next herd.

Getting an alarm into service was painfully simple – the fact of which simply served to make me even more upset with myself for not thinking of it sooner.

Thinking that the thief (or thieves) might return for more of my goodies some day, I decided to employ a warning system that was covert by nature; that is, I wanted to be alerted that someone was tampering, but I didn't want to alert the tamperer to the fact that I knew he was messing around where he didn't belong. So my idea was to use an intercom system connected to a door-actuated switch, which would key the UHF control repeater and let me actually hear what was happening on the hill. (I didn't connect the intercom to the regular open repeater because I couldn't help thinking that the thief *could* be someone who monitors and uses it – unlikely as that thought seemed to be.)

Alarm Circuit

The basic circuit I used for triggering the alarm system was similar to the one shown in Fig. 1. The circuit pictured here, developed by Motorola engineers as an automobile burglar alarm, draws less than 1 mA of constant current, so there's no need to worry about power requirements, even if your repeater is battery operated. Since the voltage required is on the order of 12V, a dropping resistor would be in order if you plan to operate from a 28V dc control system.

If your repeater site employs a UHF control repeater in conjunction with an open repeater in the VHF band, you'll probably want to employ the same operating philosophy that I used. I connected the alarm so that when it is actuated, the open repeater goes off the air and the control repeater goes on. This is accomplished by rerouting some of your existing audio connections. Cut the 2m push-to-talk lead that keys the UHF repeater and reroute it through the normally closed contacts of the alarm relay. Do the same with the 2m audio lead. The rerouted leads are shown in Fig. 2.

The way the system works is simple: The open repeater normally feeds signals to the UHF repeater through the alarm relay contacts. But when the alarm circuit is triggered, the UHF repeater becomes completely disengaged from the 2m repeater (even though the 2m system can continue to function independently, without UHF interconnect, if you want it to). The alarm circuit keeps the UHF repeater on the air until you, at the control point, transmit a tone command to reset the alarm.

While the alarm is actuated, the UHF transmitter mike circuit is being fed with a special homebrew microphone – comprised of an ordinary speaker and an output transformer. (The output transformer, by the way, can be any old tube-type "plate-to-voice-coil" transformer such as the type typically found mounted on the back of speakers in ac-dc broadcast-band radios.)

The higher the impedance of the mike side of the transformer, the better – but if you get hum, you'll have to use shielded wire and perhaps enclose the transformer in a chassis all by itself.

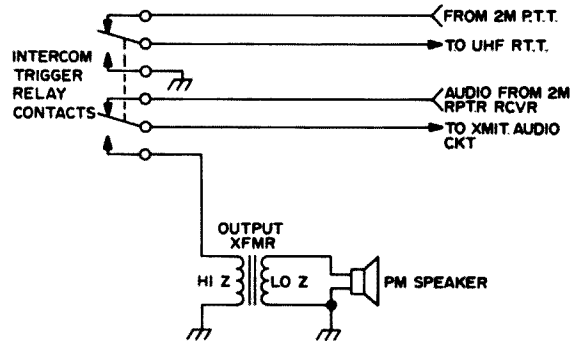

Fig. 2. The existing repeater-to-UHF audio interconnects should be reourted through the intercom trigger relay so that the UHF control repeater hears only the action at the site in the event of a burglary.

Make a few checks after you get the contrivance wired up just to see if the intercom is sensitive enough to pick up soft voices from anywhere in the repeater building. If not, just incorporate a simple audio amplifier between the speaker "mike" and the transmitter's audio line.

You may want to use the same approach I did with respect to keeping the mike hidden. I used the built-in speaker on the rpeater cabinet as the mike. (It doesn't have the best audio quality in the world and would never win any fidelity awards, but it did the job.) I installed a switch so that when I was working on the repeater I could use the speaker as it was originally intended. The hook-up for this is shown in Fig. 3.

If you use this technique, you'll have to remember to reposition the switch to the ALARM spot when you're ready to leave the site; otherwise you'll hear nothing when the burglar makes his appearance.

Triggering

Every repeater site has its own individual weaknesses from the standpoint of burglary susceptibility. Since my site had but one door and no windows, my problems were minimal. I simply installed a magnet on the door and a magnetic reed switch adjacent to it on the wall. If your site has more than one door, or a window or two, you'll want to install a magnetic reed switch at each possible entry point – or use the photoelectric alarm approach described later.

There's no requirement for using magnetic reed switches, but they offer the advantage of being very small and highly reliable. Also, it will mean that you won't have to run a wire across the door itself.

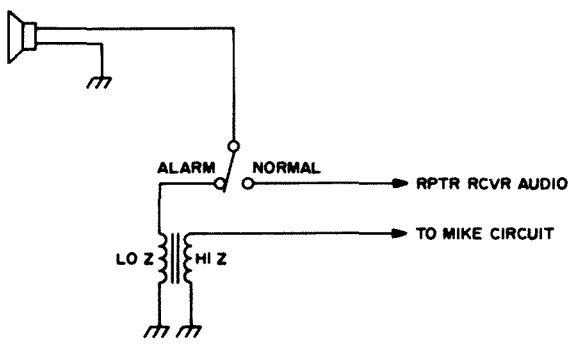

Fig. 3. A simple switch can be used to make your repeater receiver speaker double as an intercom microphone.

Relays

The reset relay should be capable of operation from whatever dc control voltage your particular repeater system uses. Since nothing more than momentary opening of the contacts is required, virtually any control system that can provide a short voltage pulse on command will be adequate.

The intercom trigger relay is a Potter-Brumfield type RS5D, which has a 6V dc coil whose resistance is 335Ω. You should stick to that relay or its equivalent if you don't want problems. A lower value of coil resistance could cause excessive current to be drawn, possibly resulting in thermal destruction of the semiconductors. Higher resistances are all right, of course, but make sure the relay contacts will be able to handle the loads you'll be switching. The P-B relay shown can handle loads of up to 2A, which should be more than adequate for the push-to-talk and audio requirements of most repeaters.

The diode across the relay coil provides a discharge path for any induced voltage spikes. Without it, the coil's collapsing field can generate a momentary high-voltage spike that might be too much for the semiconductors in the circuit. Don't install the diode backwards, either, or the diode will shunt the direct current around the relay coil directly into the SCR – which could mean curtains for your HEP 320.

Alternate Approach

If your site doesn't lend itself well to installation of magnetic reed switches, or if there are other groups who use your building, you might want to try a protection system that is less likely to be triggered inadvertently. One such method involves the installation of an "electric-eye" across the area in the building adjacent to where your repeater is located.

If you use this approach and there are other lessees in the same building, be sure to let them know of the alarm so they won't trip it when they're working on their own equipment.

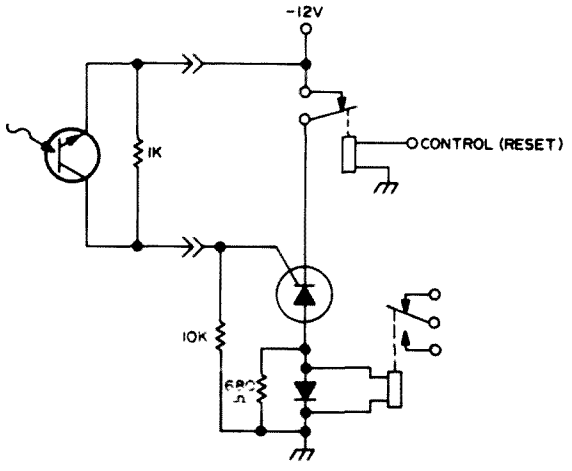

Fig. 4. The alarm circuit can be easily adapted to a photodiode beam-type protection arrangement by replacing the reed switches with a photodiode and a resistive shunt.

As you can see by comparing Figs. 1 and 4, there aren't many differences between the two alarm systems. All components that are unmarked in Fig. 4, as a matter of fact, are of the same value as those shown in Fig. 1.

You'll need a simple lens assembly to focus light from the source across the access path to the photodiode. This shouldn't prove any great problem, though, because any old flashlight should prove capable of handling that job with ease. You won't want to use batteries, of course, because they'd be gone before you could even get to the bottom of the hill. Just replace the batteries with a dc voltage from your normal control system.

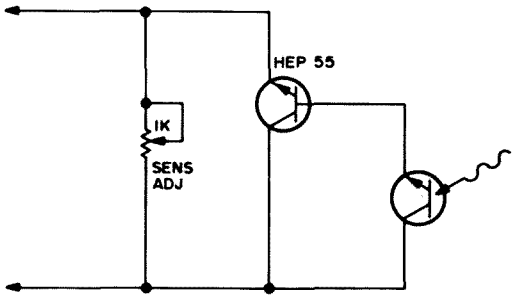

Fig. 5. Addition of a HEP 55 amplifier and substituting a pot for the fixed resistor in Fig. 4. will considerably increase the sensitivity of the circuit and will permit the light beam to span a greater distance.

If the flashlight can't provide a good, fairly high-intensity spot of light, you can modify it by moving the bulb back and forth within the reflector until an effective spot is obtained. Most flashlights will be good for about 6 ft. You can increase the sensitivity of the alarm circuit, though – thus increasing the beam distance capability – by adding a simple amplifier circuit as shown in Fig. 5.

The high-sensitivity amplifier and photodiode go into the circuit at the point in Fig. 4. where the photodiode and 1 kΩ resistor are connected. As you can see, the 1 kΩ resistor is still in the circuit, but now it's in the form of a pot so that circuit sensitivity can be adjusted.

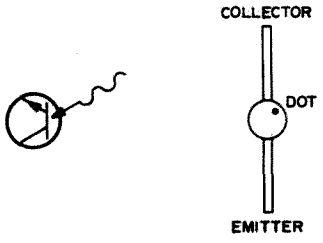

Fig. 6. Photodiode symbol and bottom view of Motorola's HEP 312.

If you haven't worked with photodiodes before, you might not be familiar with their layout. Figure 6 shows the symbol and the lead layout of the HEP 312. As you can see, the photodiode is a two-lead device, and it consists of a single PN junction. When light strikes the little collimator lens, current flow across the junction increases. With the junction reverse-biased, the increase is substantial.

Naturally, the lens of the photodiode has to be oriented for best light-capturing ability. If the repeater site is well illuminated, you'll have to put a lttle tubular shield around the diode to keep it from being triggered by extraneous light.

Semiconductor Availability

All the Motorola HEP devices described in this article are available from *Circuit Specialists, Inc., Box 3047, Scottsdale, Arizona.* The magnetic reed switches are available from *GC Electronics, Division of Hydrometals, Inc., Rockford, Illinois 61101.*

MOTOROLA T44 BASE STATION CONVERSION

Conversions of the Motorola T44 450 transceiver to 100V probably come in as many versions as there are persons converting them. Although not guaranteed to be the ultimate, this conversion does offer two distinct advantages, simplicity and versatility. A very minimum of time and components is required. Most of the parts are readily available from the average junkbox. The only items which may present a problem are the 6.3V transformers. The conversion in no way impares the operation of the T44 on 6/12V dc. All that is necessary to change from mobile to base station is to remove the vibrators and insert the jumper plugs, and position the control voltage selector to ac. Fuses F3 and F4 must be replaced with 20 amp fuses.

The first step in the conversion is to prepare the two vibrator jumper plugs. Any of several methods may be used; however, the easiest method is to cannibalize a pair of burned out vibrators for their bases or use an old 7 pin tube base. Alternatively, short pieces of 10-gage wire will fit into the vibrator sockets quite nicely. The function of the jumper is to short pins 1 and 5 to pin 7 (ground). (See Fig. 1)

The next step is to locate the small brown wire connected to terminal 3 of terminal strip TB1. (TB1 is the second transverse terminal strip from the front of the power supply.) Unsolder this brown wire from terminal 3 and move it to terminal 6 of TB1. Then wire in selector switch, connecting the two diodes and capacitor as shown in Fig. 2.

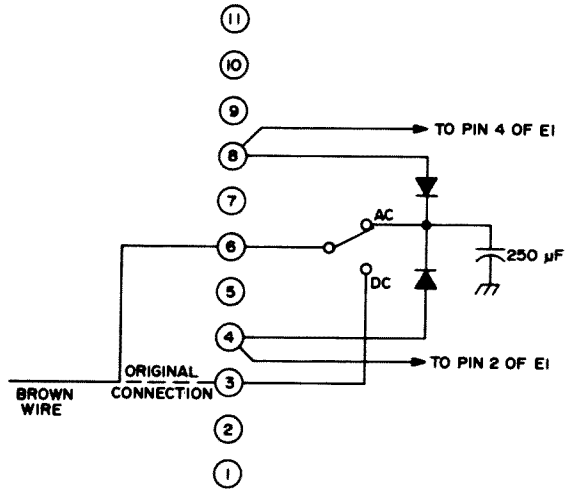

Fig. 2. Terminal board 1 (TB1)

Then connect terminal 8 to pin 4 of the vibrator E1. Connect terminal 4 to pin 2 of vibrator E1. Schematically the changes are shown in Fig. 3. This completes the equipment conversion. *(cont. on page 103)*

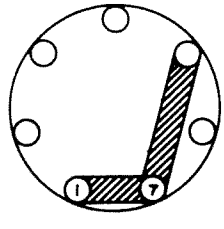

Fig. 1. Jumper plugs.

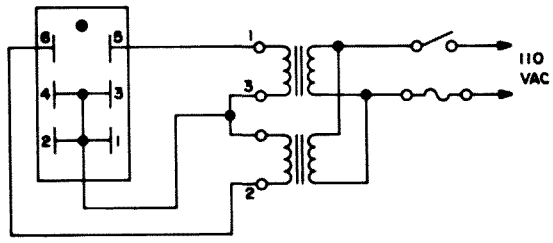

Fig. 4. External power supply.

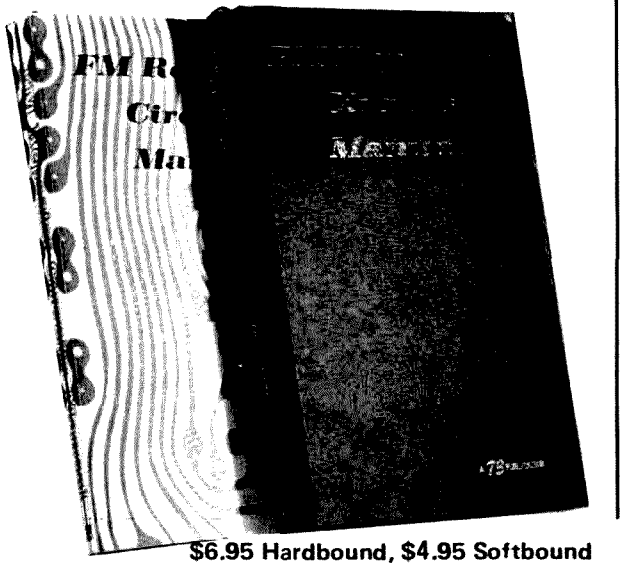

The final step is to build the external power supply. Since this is to be a base power supply, it might be handy to build the power supply and the control head into a single unit. I will only show the power supply portion. The rest will be governed by imagination, pocketbook or your Frau's aesthetic desires. The major ingredients are the two 6V-18 amp transformers. The external power supply schematic is shown in Fig. 4. The phasing of the 6V windings is important. When properly phased, the voltage from point 1 to ground and point 2 to ground should be 6V, and the voltage from point 1 to point 2 should be 12V.

REPEATER CIRCUITS MANUAL

If you're into FM, you'll want to have this incredibly complete manual of FM circuits. You don't have your own repeater yet? Well, you've been thinking of it . . . admit it. Some fellows even have gone so far as to have a repeater in their car so they can extend the range of their hand units!

This book, over 300 pages long, has just about every circuit that you could possibly want. Many of these have been published elsewhere, but many haven't, too. And you can go out of your mind trying to find a circuit when you want it . . . so here they are, all in one handy place!

Fixed Base Operation of the HR-2 Transceiver

he Regency HR-2 Mobile Transceiver is a fine, high-quality piece of mobile 2-meter FM gear.[1] However, its "no-frills" design allows for quite a bit of individual leeway in the modification of the HR-2 for base station use.

Power Supply

Since the HR-2 operates from +12V dc, the first order of business is the design of a power converter between wall juice (117V ac and 12V dc.)Figure 1 shows the schematic diagram of a supply designed to give 13.0V on transmit and 13.4V on receive. T1 is any transformer that will give 16–19V ac out at 2 amps. There are several companies[2] that make such transformers, or a 12.6V and 6.3V filament transformer may be wired in series to give the required voltage. Diodes D1 through D4 form a full-wave bridge rectifier. C1 is a 7000 μF filter capacitor (I used seven 100 μF capacitors in parallel.) Any combination yielding over 6000 μF of capacity should work to remove the ripple from the bridge rectifier. Q1–Q2 form a regulator-filter to regulate the +22 down to +13V. When the transceiver is on transmit, 25W is dissipated in Q1, so be sure to heat-sink it well. Q2 will draw a healthy slug of current under accidental short-circuit of the output, so heat-sink it well also. D5, D6 and the emitter-base junction of Q2 set the output voltage, and they must add up to the desired output voltage (12.0 + .7 + .7 = 13.4V output). R1 is used both as a surge-limiting

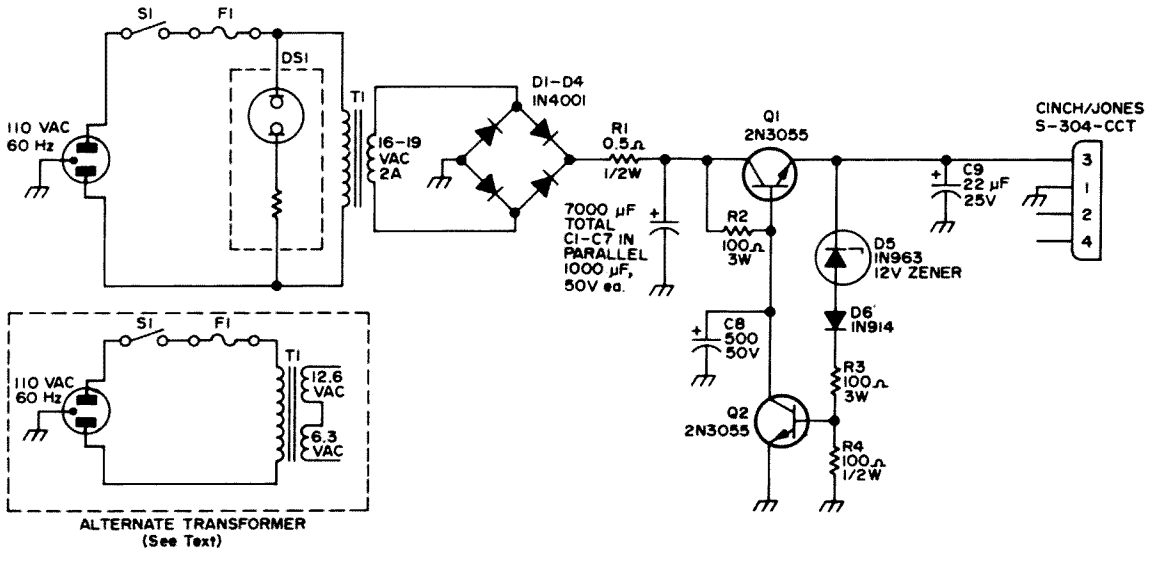

Fig. 1. Ac power supply. Parts data –C1–C7: 1000μF 50V dc; C8: 500μF 50V dc; C9: 22μF 25V dc; D1–D4: IN4001 50 piv lamp; D5: IN963 zener diode, 12V; D6: IN914 silicon diode; I1: neon panel lamp assembly; F1: 1A slo-blow fuse; Q1–Q2: 2N3448 or 2N3055; R1: 0.5Ω ½W; R2–R3: 100Ω3W; R4: 100Ω ½W; T1: 117V – 16 to 19V at 2A.

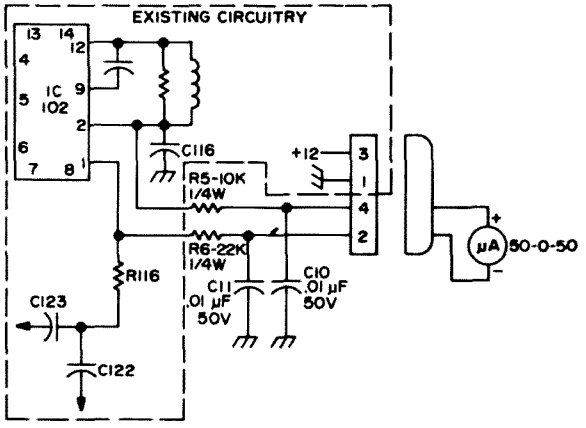

Fig. 2. Installation of zeroing meter. Parts data – R5: 10 kΩ ¼W; R6: 22 kΩ ¼W; C10–11: .01 µF 50V dc; M1: 50- 0 - 50 µA panel meter.

resistor and as a current-sensing resistor to be used later. Do not use a lower valve for C8 than 500 µF, or the supply may oscillate and self-destruct Q1 and Q2. Power connections are made to pins 1 (ground) and 3 (+12) of a female 4-pin Jones plug (note – the instruction manual shows pin 1 to be +12 and pin 3 to be ground – it might be wise to check the internal wiring of your HR-2 before you hook up the power cable. Mine was wired the opposite from the manual.) The extra pins (2 and 4 of the Jones power plug) will be used later as output to the zero-center meter.

Zero-Center Meter

Another "frill" useful as a base station accessory is a meter in the discriminator circuit to detect the relative error of other stations or for "zeroing" another transmitter frequency. Figure 2 shows how this modification is accomplished. IC 102 is the original discriminator, with output at pin 1. Pin 2 is

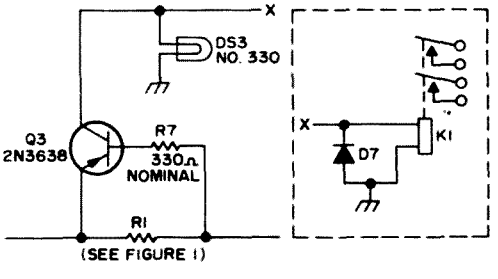

Fig. 3. "Transmitter On" light modification. Parts data – D7: 1N4001 diode; 12: 12V pilot bulb; Q3: DNP 2N3638; R7: 330Ω ¼W nominal (see text); RL1: 12V relay.

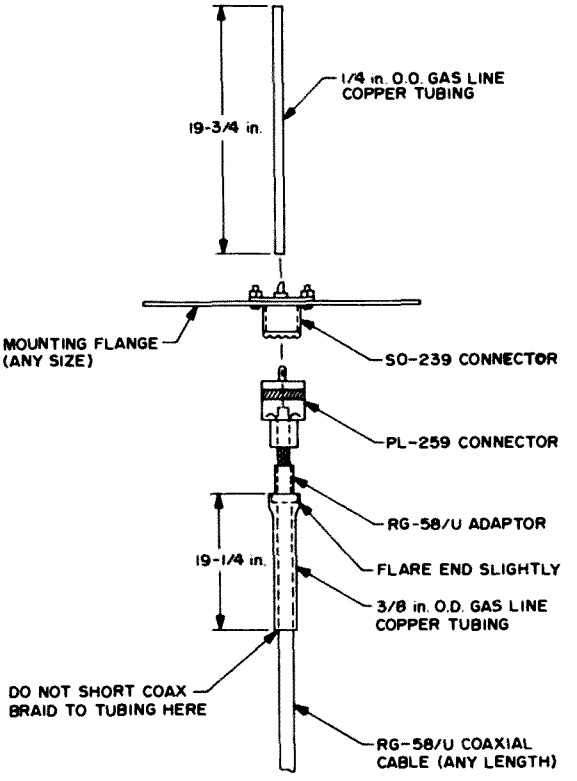

Fig. 4. Fixed station antenna for $1.

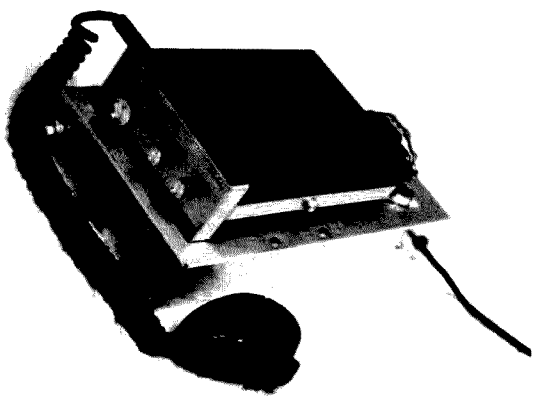
a constant dc voltage representing zero frequency error. Pin 1 varies about this voltage plus or minus depending on whether the received frequency is high or low. Decoupling filters R5-C10 and R6-C11 provide the necessary isolation and meter multiplication for a full-scale deflection of M1 at ±25 kHz frequency error.

Transmit Indicator

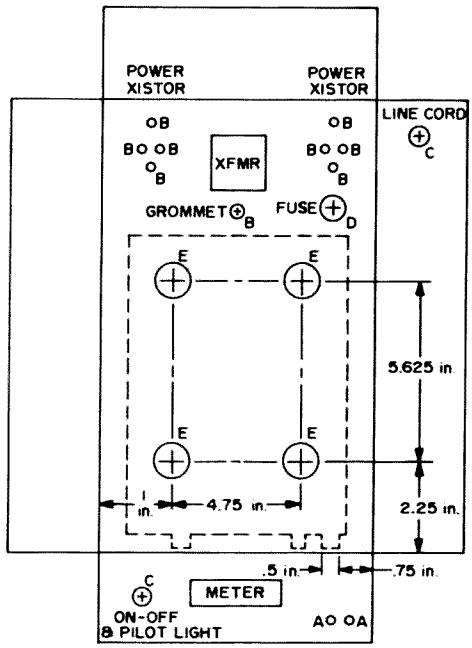
Under certain circumstances, a "transmit" indicator is useful. It may prevent inadvertent keying of the transmitter or a stuck microphone button putting out unwanted A1 emissions.

Figure 3 shows the addition of the 3 parts to the power supply for this "transmitter on" light. When the current through R1 increases above an ampere or so, Q3 is turned "on," and provides current to lamp 12. The current through the lamp is set by R7 to give a normal, above normal, or less than normal brilliance. Q3 is thermally adequate for the most normal operations,



but you may wish to heat-sink the device or use a heftier device if you are particularly long-winded. A 12V relay (shown on the schematic inset) may be substituted in place of the light to control other functions, such as +12 to an external power amplifier, a 110V light bulb, or other "power" devices.

Antenna



Since the use of the transceiver as a base station is an off-and-on thing, no great pains were taken to make the ultimate in gain or match with the base antenna. Figure 4 shows how a dollar's worth of goodies (except cable) makes a fairly respectable antenna with a resaonble vswr (less than 1.5:1) across the 146–147 MHz band (less than 2:1 from 144–148 MHz). Tuning is non-critical, and the gain is slightly superior to the more complex groundplane[3]. The basic construction is that of a coaxial sleeve monopole. One-eighth in. copper gas line is used for the radiating element and 3/8 in. gas line is used for the sleeve. These lines are available at your local auto parts house or "do-it-yourself" handyman shop for about 25¢ a foot. The SO239–PL259 are standard items at the local surplus shop or radio parts shop.

Construction

The photograph shows the completed base station. A 7x2x13 in. chassis was selected so that the transceiver could be set on it to form the base plate. The power supply components are mounted in back of the transceiver on the chassis, and the underneath of the chassis is almost entirely taken up by filter capacitors. Figure 5 shows the drilling template I used to drill and punch the chassis.

Completed unit.

HOLE CHART		
SYM	SIZE (DIA)	QTY
A	1/8 in.	2
B	1/4 in.	9
C	3/8 in.	2
D	1/2 in.	1
E		4

Fig. 5. Drilling template for home station adaptor.

Layout and parts placement may vary widely from my design; there are no critical parts placement problems with a dc power supply such as this one. However, keep C8 close to the base of Q1 to avoid the aforementioned stability problems.

Final Test

Before plugging the transceiver in, load the power supply output with a 10Ω 10W resistor and measure the dc voltage. It should be 13V ± the tolerance of your zener. No load voltage should be 13.4V ± the tolerance. A final check of the antenna vswr, and your excellent mobile rig is now an excellent base station also.

1972 REPEATER LIST

The entries in this list are correct as nearly as we can manage right down to press time for this issue. Between indifference on the part of repeater managers and clubs toward getting their repeaters listed, a daily change in channels and the appearance of new repeaters on an almost daily basis, no list can ever be perfect. The list presented here is by far the most up to date available anywhere . . . and you merely have to keep tab on the repeater update column in the monthly 73 newspages to keep this list in near-perfect shape.

We ask that you take it upon yourself to let us know at 73 if you find any errors in the listings presented . . . or if you hear of any repeaters coming on the air that we do not have listed . . . or any changing frequencies . . . or going off the air. Send us a card, a QSL, a note, a letter, or even a radiogram via the traffic nets . . . but send. The more accurate we can keep this list the more valuable it will be to everyone . . . and the more fun we will all have with FM . . . the Fun Mode.

Repeater access methods are listed so: T1.95 means tone burst, 1950 Hz; W1.7, whistle-on center frequency 1700 Hz; TT, touchtone access (consult repeater club for access code); PL, private line (consult repeater club for exact frequency or reed number). Frequencies are listed so: figures in the last column (e.g., 34–94) refer to the 146 MHz segment of the two meter band. If different segments are used in the input or output or both, frequencies are listed with UHF, six meter, ten meter or 220 MHz frequencies.

NEW ZEALAND

New Zealand has been working on a 2 meter band plan for the country, with provision for all modes of operation.There are FM simplex channels every 50 kHz from 145.8 to 146.2 MHz, with 145.85, 146.0 and 146.15 MHz, as the prime channels. 146.0 MHz to be first. On the FM repeater side they have allocated four channels on 700 kHz spacing. A pity, as it does not make them compatible to Australia. Inputs on 146.3, .35, .4 and .45 with the outputs on 145.6, .65, .7 and .75. The three-channel AM repeater systems have inputs on 144.6, .65 and .7 with the outputs on 145.725, .775 and .825. 144.8 MHz is set aside as an RTTY net frequency. The beacons are on the "hundred" equal to the call area, e.g. ZL1 on 145.1, ZL2 on 145.2, ZL3 on 145.3, and ZL4 on 145.4 MHz. The segment 144.0 to 144.1 MHz is set aside as DX and experimental working. 144.1 to 144.5 MHz is a general working segment.

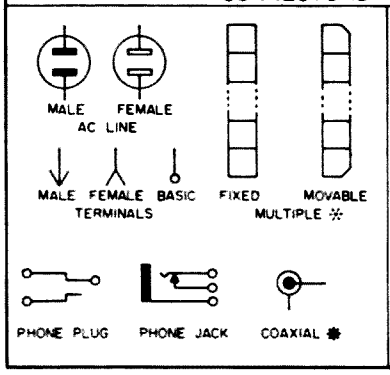
NOTE THAT CURVED PORTION OF SYMBOL ALWAYS DESIGNATES OUTSIDE FOIL OF FIXED CAPACITORS (EXCEPT ELECTROLYTICS, WHERE IT INDICATES THE NEGATIVE TERMINAL)

THE CURVED PORTION IN THE CASE OF A VARIABLE WILL INDICATE THE MOVABLE PART



* INDICATE POLARITY, AND VALUE IN μF

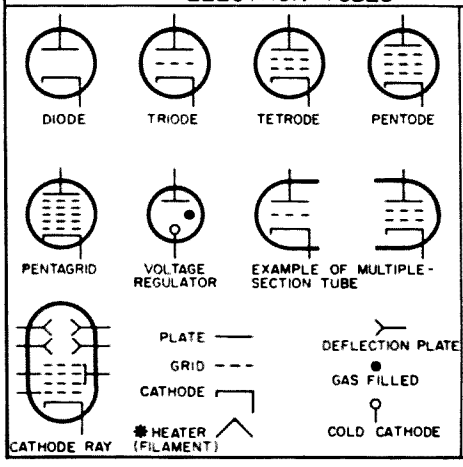
WHEN OTHER THAN ELECTROLYTIC, VALUES ARE ASSUMED TO BE pF WHEN 1 OR GREATER, AND μF WHEN LESS THAN 1

CONDUCTORS

CONNECTORS

SHOULD NONE OF THE SYMBOLS DESCRIBED HERE SEEM TO MATCH YOUR SITUATION, DESCRIBE THE CONNECTOR AND/OR LIST THE MANUFACTURER'S PART NUMBER

* FOR ANY COAXIAL-TYPE CONNECTOR, SUCH AS RF, MICROPHONE, PHONO, ETC.



※ NUMBER THE BLOCKS TO CORRESPOND TO TERMINAL MARKINGS, WHEN APPROPRIATE

CRYSTAL

ALWAYS INDICATE CRYSTAL FREQUENCY (IN kHz, MHz, ETC.)

ELECTRON TUBES

ALWAYS LABEL ELEMENTS WITH TUBE PIN NUMBERS

REFER TO TUBE MANUAL FOR DATA ON INDIVIDUAL TUBE TYPES

* FILAMENTS OR HEATERS (WITH THE EXCEPTION OF DIRECTLY-HEATED CATHODES) SHOULD BE SHOWN EXTERNAL TO TUBE CIRCLE, AND PREFERABLY IN THE POWER SUPPLY

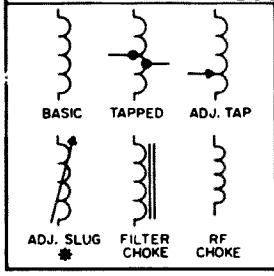
FUSE

INDICATE CURRENT, VOLTAGE RATINGS, AND SLO-BLO, ETC., AS APPROPRIATE

GROUND CONNECTIONS

CHASSIS GROUND SYMBOL IS NORMALLY THE ONLY TYPE USED IN SCHEMATICS

EACH GROUNDED CIRCUIT COMPONENT WILL BE SHOWN CONNECTED TO AN *INDIVIDUAL* CHASSIS GROUND, UNLESS A COMMON GROUND BUS IS ESSENTIAL TO PROPER CIRCUIT OPERATION



HEADSET

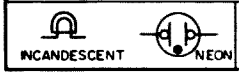
NORMALLY USED IN BLOCK DIAGRAMS, BUT MAY BE USED IN ANY SCHEMATIC WHERE CONNECTED DIRECTLY INTO CIRCUIT WITHOUT PHONE PLUG

INDICATE IMPEDANCE IF VALUE IS CRITICAL

INDUCTORS

INCLUDE ALL NECESSARY DATA INCLUDING ANY OF FOLLOWING INFORMATION WHICH IS APPLICABLE:

- WIRE SIZE & TYPE
- COIL OR FORM O.D. OR I.D.
- NUMBER OF TURNS AND/OR LENGTH
- MANUFACTURERS PART NUMBER
- TAP POSITION ABOVE COLD END

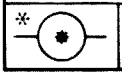


* FERRITE CORE WILL BE ASSUMED UNLESS BRASS IS SPECIFIED. INDICATE TYPE OF FERRITE, IF CRITICAL

KEYS

* BE SURE TO DESIGNATE "DIT" & "DAH" CONTACTS

LAMPS



INDICATE MANUFACTURER'S PART NUMBER AND/OR VOLTAGE & CURRENT RATING

LOUDSPEAKER

INDICATE VOICE COIL IMPEDANCE & POWER RATING, ETC., WHEN CRITICAL

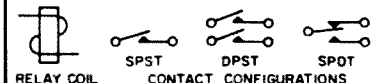
METERS

* INDICATE TYPE OF METER HERE (μA, mA, V, ETC.)
※ INDICATE SCALE RANGE HERE (0-1, 0-50, ETC.)
DON'T FORGET TO INDICATE PROPER POLARITY

MICROPHONE

NORMALLY USED IN BLOCK DIAGRAMS BUT MAY BE USED IN SCHEMATIC WHEN WIRED DIRECTLY INTO CIRCUIT WITHOUT CONNECTOR

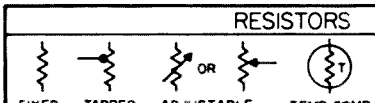
INDICATE TYPE (CARBON, XTAL, ETC.)



MOTOR

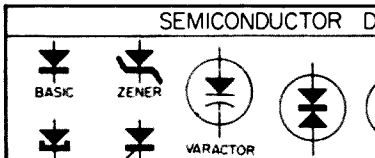
LABEL AS MOTOR, FAN MOTOR, ETC.

INDICATE OPERATING VOLTAGE & CURRENT AND/OR MANUFACTURER'S PART NUMBER



RELAYS

SPECIFY COIL VOLTAGE, RESISTANCE, ETC., AND/OR MANUFACTURER'S PART NUMBER

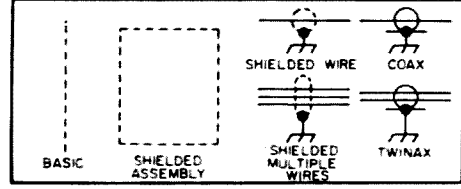


CONTACT CONFIGURATIONS SHOWN ARE BASIC AND MAY BE EXPANDED

RESISTORS

INDICATE VALUE, IN OHMS(Ω), KILOHMS(K), OR MEGOHMS(M), AND/OR MANUFACTURER'S PART NUMBER.
1/2W 10% IS ASSUMED UNLESS OTHERWISE NOTED

SEMICONDUCTOR DIODES

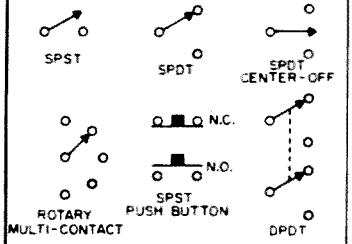


INDICATE MANUFACTURER'S PART NUMBER AND/OR APPROPRIATE RATINGS

REFER TO MANUALS FOR SYMBOLS NOT SHOWN

S INDICATES SILICON
G " GERMANIUM

ELECTRONIC SYMBOLS

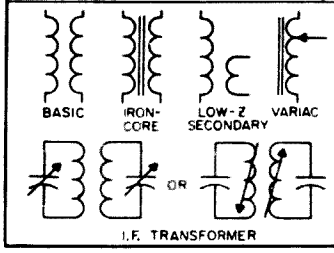


SHIELDING

SHIELDS ARE ASSUMED TO BE GROUNDED UNLESS OTHERWISE NOTED

INDICATE IF SHIELD ON CONDUCTOR IS TO BE GROUNDED ONE END ONLY, & SPECIFY WHICH END

SWITCHES

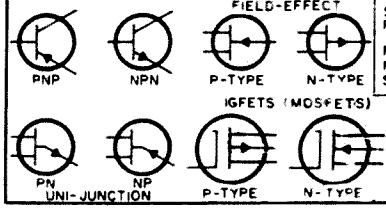


ONLY BASIC CONFIGURATIONS ARE SHOWN. COMBINE OR EXPAND AS NECESSARY TO SUIT

SELF-HOLDING SWITCH OPERATION IS ASSUMED UNLESS SPRING-RETURN IS SPECIFIED

NON-SHORTING TYPE IS ASSUMED UNLESS SHORTING TYPE IS SPECIFIED

SWITCH SECTIONS WHICH ARE SIMULTANEOUSLY OPERATED OR GANGED SHOULD BE JOINED WITH A DOTTED LINE



TRANSFORMERS

SHOW (4) LOOPS EACH WINDING EXCEPT (6) LOOPS ON HIGH-VOLTAGE SECONDARIES AND (2) ON FILAMENT WINDINGS AND NON-RESONANT LOW-Z RF COUPLING LINKS

TRANSFORMER DESCRIPTION SHOULD INCLUDE MANUFACTURER'S PART NUMBER AND RATINGS, OR CONSTRUCTION DATA

TRANSISTORS

SPECIFY MANUFACTURER'S PART NUMBER OR RATINGS

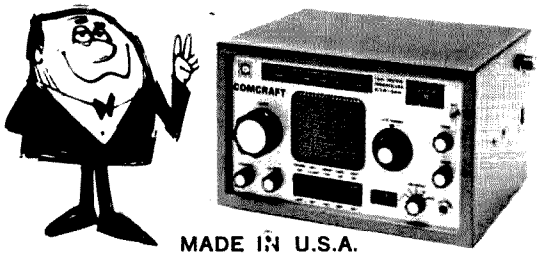
TESTING THE COMCRAFT CTR-144

Can an FM nut live comfortably with a tunable receiver and a vfc transmitter?

As an old time two meter addict my hands began to shake with anticipation as I plugged in the new Comcraft transceiver, just looking forward to being able to tune the receiver dial and get back to the old familiar concept of frequency being marks on a slide rule dial instead of numbers on a switch.

Sure enough, as I tuned from 146.5 to 147.0 there were all the repeaters, blasting through. And even though this segment of the two meter band takes up only about 3/8" of the dial, I still could identify most of the repeater channels by their position on the dial. The receiver was quite sensitive and I was able to hear repeaters right on down to New Haven, some 150 miles or so away.

The most exciting discovery was that "secret" repeater up in Manchester (NH) up above 147 MHz. I knew their input frequency, but had not been able to get them to spill the beans on the output so I could get crystals and their promises of getting crystals for me had been dragging on for a couple of years, so when I tuned across the repeater output I let out a whoop and zeroed in the Comcraft vfo and called in. There was a stunned moment of silence and then they acknowledged me. I didn't tell them how I found them.



The vfo is stable enough to work through FM repeaters with no problem. My counter shows it to hit within 25 Hz or so each time it is keyed! There are three internal crystal positions plus a front panel jack for a fourth crystal position. The rig uses the very popular 8 MHz FT-243 type crystals, which are still around by the thousands from WW II.

The CTR-144 is basically an up-to-date solid state Communicator. It tunes from 144–148, with enough overlap to bring joy to the MARS and CAP enthusiasts. My unit tuned from 144.00 to 148.15 on both receiver and vfo, but this could be easily changed enough to add or subtract a half MHz or so by touching the band-setting capacitors.

The power supply is built in for 117V ac operation, plus the usual 12V dc power cord for mobile use. A little battery test button on the front panel lets you check the battery condition. This test button may not be of great interest for mobile applications, but if the unit is used in conjunction with the accessory CBP-12 Comcraft battery pack, it will tell you how things are going. This battery pack is automatically recharged by the ac supply, by the way.

2 Rigs in one!

THE COMCRAFT CTR-144

MADE IN U.S.A.

The First AM-FM Solid-State Transceiver For Two Meters

No longer is it necessary to choose between AM and FM on two meters. Now you can have both in one compact unit. Join the gang on the new FM repeaters yet still be able to "rag chew" with old friends either AM or FM anywhere in the two meter band.

COMPARE THESE FEATURES

TRANSMITTER:

- Built-in VFO (Frequency converted for stability)
- AM and FM both crystal and VFO
- Four transmit crystal positions (8 MHz)
- 12 watt input AM and FM
- High level transmitter modulation on AM
- Bandpass coupled transmitter requiring only final tune and load
- Three internal transmit crystal sockets with trimmers for netting
- One transmitter crystal socket on the front panel
- Deviation limiting
- 146.94 MHz crystal included

RECEIVER:

- Double conversion
- Crystal controlled first conversion
- MOS FET receiver front-end
- Integrated circuit limiter and discriminator for FM
- Envelope detector and series gate noise clipper for AM
- Built-in squelch for both AM and FM

GENERAL:

- Separate transmitter and receiver tuning
- Built-in 115VAC power supply
- Direct 12VDC operation for mobile or portable operation
- Optional portable rechargeable snap-on battery pack available
- "S" Meter also used for transmitter tune up
- Military style glass epoxy circuit boards
- Anodized lettering and front panel
- Baked epoxy finish on the cabinet
- 47 transistors, 22 diodes, 1 integrated circuit
- Dimensions: 10¼"W x 6¼"H x 7½"D

Warranty—90 Days Parts and Labor

The CTR-144 is available at your DEALER

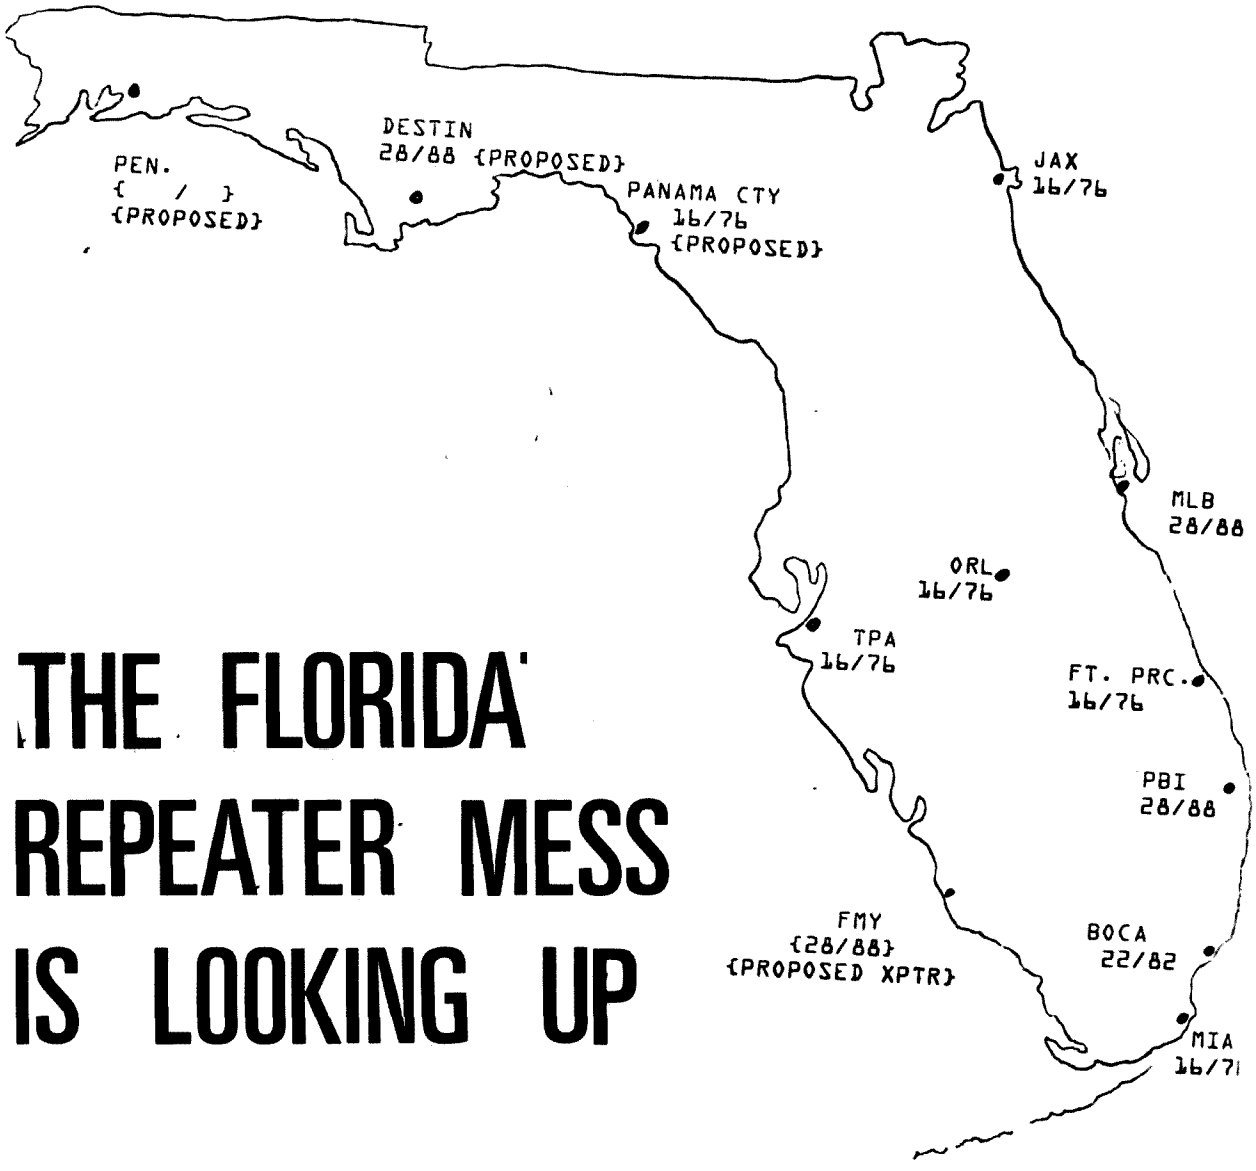
Write for more information or use READER SERVICE

The receiver gets its selectivity and rejection of images by a clever system of i-f management. The first local oscillator is at 65 MHz and is crystal controlled. This doubles to 130 and the output is in the 14–18 MHz range which is tuned by the first i-f. The second local oscillator drops the i-f to 2 MHz and then the signal is channeled into either an FM or AM detector.

The 65 MHz oscillator is used by the transmitter to beat the 7–9 MHz vfo up to 72–74 MHz. This is then doubled to the output frequency.

While I find a counter quite helpful in putting the CTR exactly on a repeater input frequency, I have had little trouble zeroing in just by listening for the repeater squelch-tail and tickling the vfo dial until I hit the pass-band. While visiting New York I cut a 19" length of coathanger and stuck it into the antenna conductor, zipped onto WA2SUR's input on 146.19 and found myself talking with a number of old friends. This was from my livingroom in Brooklyn about five miles away!



While I appreciate the benefits of channelized operation as much as anyone, I do have to admit that I like it a lot that I can now tune the 144 MHz band complete and check to see what is going on. And who can afford all the crystals it takes to get all of the repeaters? With new repeaters coming on the air by the week, who can keep up with it? I'd be ordering more crystals every week and, at $4 to $6 each, this is a luxury beyond the means of a mere magazine editor.

One thing I did learn from being able to tune the entire 144 MHz band . . . the FM activity is just about the only activity that I'm going to hear up this way. I may be able to get into seventeen FM repeaters from my home, but I have heard one and only one AM signal on the band in several weeks of listening. I haven't had a good chance to tune the entire band since my NC-300 receivers were swiped a few years ago. The band sure has changed!

The Comcraft CTR-144 may not meet the demands of the purist FM old timer, but it sure does do its job well and is a lot of fun. And it will run AM if you need it!

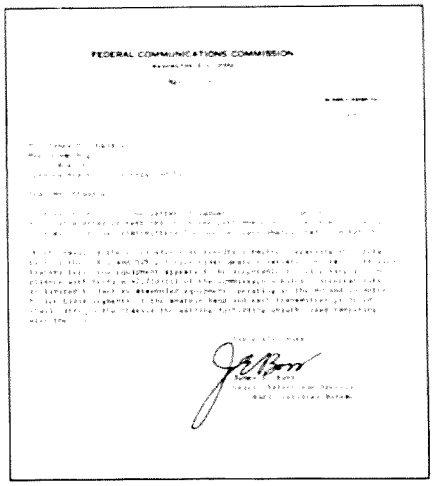
THE FLORIDA REPEATER MESS IS LOOKING UP

Jeffrey R. Harrow WA4RLG
1336 S. Biscayne Pt. Rd.
Miami Beach FL 33141

I'm not all that old (22) and yet, as I look back about six years it seems an immensely long time ago that Glynn WA4LHK, Bill WA4MKD, myself, and the rest of the renowned N.O.M.A.R.C. group put on (to my knowledge) the first amateur two meter repeater in Florida. It consisted of a preprog. G.E. into two ground planes up about five stories – and we were ecstatic with a one to two mile range.

Well, as you can see from the sketch, Florida took to two meters with a vengeance. So much so, in fact, that for the past couple of years, a problem pretty old to the California and New England areas has become evident. With so many repeaters in operation, and with about 90% of them on 34/76, we had the old problem of high powered base stations in Tampa keying the Miami repeater, and vice versa. After a while, the Melborne repeater came on, and later was joined by the Boca Raton machine, 43 miles north of Miami. It got to the point where most people were shutting off their receivers because they were having to listen to too many one-sided conversations not meant for them.



THE NOVICE VFO

We the People of MicroComm, recognizing the **inalienable right** to QSY, **freedom** to work DX and **independence** to throw your crystals away, **do ordain and estadlish** the Novice NVX-1 Variable Crystal Oscillators. Fully approved by the **Constitution** and the F.C.C.

The NVX-1 works like a V.F.O. with your XMTR.

Coverage: 3702 – 3748 KHz
7152 – 7198 KHz

Declare your Independence and order today at the Introductory Price $39.75, p.p.d., wired. Guaranteed and certified for one full year. California residents add 5% sales tax.

Then, about eight months ago, the Orlando repeater came on in the center of the state. Poor Melborne. Poor Tampa. Orlando base stations were consistently keying up their repeaters with 20 dB to full quieting signals. Melborne even changed their receiver antenna orientation to reduce the problem (and in doing so, though, they removed repeater coverage from a rather barren stretch between Orlando and Melborne, a nice place to have a flat tire). At the same time down in Miami, the Boca repeater was going strong. It put usable signals into Miami, and communications took on quite an interesting assortment of squeals, grunts, and shouts of "Hey, control station, please shut this &S#¢% machine down so I can talk to Boca."

Up to now I've described a situation very familiar (or it may soon be) to most of you. Here is the solution that the South Eastern Repeater Association committee, headed by Hal Greenley K4GYO, proposed, and which was adopted by all of the S.E.U.S. repeaters:

On January 15, 1972, all of the S.E. repeaters changed their main input frequency to either 146.16, 146.22, or 146.28 MHz. The specific frequency allocations were made by the committee, based on factors including location, seniority, adjacent repeaters, etc. These inputs are "open," that is, no tone coding of any kind. Each repeater also maintains a 146.34 MHz input. This 34 input is Touchtone coded with a different code assigned to each repeater. The code performs a latching function (at the discretion of each repeater) or a time delay. For instance, if the Miami repeater 34 input hears a digit one, it will open, and leave open, the 34 input of the machine, until it hears another digit one, when it will close the 34 input. The 16, 22, or 28 inputs will have priority over the 34 input. So if a station comes on 16, the 16 station will take over, or capture the repeater, even if a station is already transmitting on 34.

Several months later, each repeater will change its output frequency to 146.76, 146.82 and 146.88 MHz respectively.

Now, what have we gained from this mildly expensive and time consuming area-wide change?

First of all, by careful frequency assignments, mobiles using one repeater will not – under normal conditions – be able to key up the closest repeater using the same channel. Notice that I said mobiles. What about base stations?

All base stations will be requested to use the 146.34 inputs. This serves several purposes. First and foremost, it allows a mobile, any mobile, and even an HT, to break into a chat by a base station to request help, report accidents, etc. (Remember our justification for existence – public necessity, interest, and convenience.) Secondly, it allows high powered base stations in Miami for instance, to talk through the Orlando repeater without keying up, or tying up other repeaters around the state. Toward this end, all the individual repeater need do is to keep its 34 input tone coded off when not in use. The repeaters with 34 coded off will not be bothered by the long haul conversation. Of course, two cross-state conversations at once could pose a problem, but then nothing (yet) is perfect. I might also point out that traveling mobiles who can't cram in two more sets of crystals can utilize the 34 input of any repeater he is near with his Touch-tone pad. The only disadvantage for mobile use of 34 is that several repeaters will only operate one centralized 34 receiver while they may have several satellite receivers on their main discrete frequency. Third, if more areas conform to these standardized channels (and they are), only three sets of crystals will be necessary to cover most of the country. Rick WB4IES, and I recently took a light plane trip from Miami to San Francisco and back; we know we missed more repeaters than we worked. Also, the many combinations of PL tones described in several magazines won't be necessary.

This is the beginning of the standardization which is so necessary to our continued expansion. This plan, which you notice incorporates 600 kHz spacing between the repeater transmit and receive frequencies allows more practical one-site repeaters. Another not so obvious advantage is that standard 600 kHz spaced, 60 kHz staggered channels make frequency synthesis somewhat easier to produce.

Certainly there are some objections and disadvantages to this plan. The most often heard seems to be the expense of the new crystals and the fact that "We were here first, why should we move?" Well, the expense, especially in the field of ham radio, is rather minimal. It is interesting to note, however, that most forms of improvement and progress cost some money. This isn't the first and certainly not the last such instance. To the other objection, that of "squatters' rights," I say this: Each motorist on the road has given up some of his freedom – such as having to stop at a traffic light when he is in a hurry. To go further, the nations of the world have given up some of their freedoms – such as not indiscriminately testing nuclear weapons. This giving up of "rights" is done in order to bring about the greater good of all. The same thing holds true here. I read a very disturbing article recently where a group of irate two meter hams had a repeater evicted from a beautiful mountain top site because it was bleeding into their receivers 30 kHz and ten miles away. At this, I can only shake my head.

All in all, two meters is growing; well in some areas, and poorly in others. If we all give just a little we may one day see a beautifully interlinked repeater system not only in Florida but extending toward the rest of the country with autopatch facilities and possibly FAX or TV. Atlanta and Florida are even now beginning to talk of a link!. And remember, amateur satellites can do more than broaden our horizons – they can literally jump them!

Repeaters are becoming more prevalent, and with a consistent, carefully planned *system*, each repeater will be covering a larger and larger area without bothering its neighbor. And remember, if the FCC receives many complaints from irate repeater groups they could justifiably impose their own rules. We have traditionally been a self-policing group, and it would behoove us to retain this system.

The future? It's governed by what we do today! Remember how the fantastically complex Bell system started.

73 Magazine

Ross and White RW-Band Tranceiver

The Ross and White RW-Bnd 2 meter FM transceiver is one of the newer entries to the FM market place, and it brings with it several unique features.

You can put it in your glove compartment, it is so small. The front panel mike socket lets its trim design slide into narrow places, like the empty hole in your dashboard where the AM radio used to be. If you prefer to keep it outside, you can mount it underneath the dash or on the transmission hump with the mounting bracket that is included. And this rig is portable too. You can use it with a shoulder strap and flashlight batteries. Its size is deceptive because it is loaded with features. Keep reading.

The little knob at the side is for the built-in tone burst encoder. More and more repeaters are requiring tones to activate the transmitters and other functions of the repeaters, such as low band links. In some areas that have several repeaters with the same input frequency, a different tone is required to turn on each particular machine. Other rigs require externally connected boxes that have the tone generators inside. The generator is already inside the RW-Bnd. These tones are easily reached for field adjustment and the three switchable positions should be sufficient even for the frequent traveler. Since the tone circuits use ICs, they are trouble free and should require no maintenance at all.

You will notice that there are four knobs on the front panel. There is a volume and a squelch control as with all others. To turn it on, you turn on the volume and adjust it for a comfortable noise level with the squelch open. Right? Wrong. Once you have adjusted these two controls you should not need to adjust them again because the main power switch is included in the power level switch. There are three power levels (plus 'off') that offer a variety of operating conditions. The low power slot is fine for talking to the mobile who is following you. No need to tie up a lot of other people on the direct channel. The medium power level is perfect for keeping in touch with the base when you head out for a loaf of bread. Incidentally, these two levels are satisfactory for portable operation using batteries or other situations where low current power suplplies only are available, such as when you are on a business trip. The usefulness of this rig for emergencies is self-evident; low current drain, built in tone burst, and small size. If there is no emergency and you are just talking to the distant repeater several cities away, the high power position is the ideal level as this allows the rig to run ten-plus watts output to the antenna.

Do you have visions of plugging your rig in and pushing the mike button and watching the relative rf output meter quickly flash to maximum and then crashing to zero? This will not happen with the RW-Bnd because it has

a protection circuit that prevents the final transistor from blowing out if the swr is too high, such as when you forget to connect the antenna or a low tree branch takes it off.

The circuitry is modern and of advanced design. For example, the transmitter uses an IC oscillator. Most other rigs do not have an IC here. In the receiver, the sharp i-f does not block or get cross-talk from adjacent channels. Once inside the rig, you will notice that there is a lot of room. You will be grateful for this when you try to change crystals for the transmitter or receiver becuase there is room to get a couple of fingers in there and you do not have to use a pair of pliers that might pinch the crystal. Each rock has a trimmer capacitor to let you get it exactly on frequency, transmit and receive. Twelve channels are sufficient for most areas and this is what you have in the RW-Bnd. In case one of your local repeaters has not switched to the standard 600 kHz spacing, crystal jumpering is easy.

Once the rig is installed, the clear, clean and plentiful audio will strike you. The front mounted speaker is what does it. The audio is not directed at your feet nor is it muffled in the maze of wires behind the dashboard. You will not need to hook up an external speaker to hear this one. Another useful feature is the accessory jack on the rear panel. It is connected to nothing. Your own needs and imagination are the determining factors here. Do you use a Touchtone pad? Tie it in here. Do you use a continuous tone squelch system (PL)? Attach it to this plug. Perhaps you want to run the audio output to another speaker in the rear of the car. It is easily done. You can even bring out test points for monitoring the functions of the rig.

One other valuable contribution the Ross and White people have given the ham for maximum enjoyment of his FM rig is a complete instruction manual. Book is a better word to use. It has pictorials, parts placement pictures, voltage tests, operating theory, and more. It is a valuable volume for the proud RW-Bnd owner.

For more information about this great rig, contact Ross and White at *50 West Dundee Road, Wheeling IL 60090*. . . .Staff

FROM JIM, WN5COZ

NOAA Studies Ionospheric Effects of Thunderstorms

Reprinted from Collector and Emitter, a publication of the Aeronautical Center Amateur Radio Club of Oklahoma City, Oklahoma.

Scientists of the Commerce Department's National Oceanic and Atmospheric Administration have found that thunderstorms transmit tremendous sound pulses into the ionosphere 125 miles above the earth.

By observing these high-altitude perturbations with carefully sited radio transmitter/receiver arrays, the scientists have determined that a pulse can give the ionosphere a three-mile lift directly above the originating storm.

Dr. Kenneth Davies of NOAA's Apace Environment Laboratory at Boulder, Colorado, says the ionosphere begins responding to thunderstorms about the time their tops have reached the 40,000-ft level.

The turbulence within the thunderstorm produces pulsations which travel through the atmosphere as pressure waves. Unlike radio waves, which penetrate the atmosphere without affecting the natural gases through which they pass, these pressure waves move by a

CAMP ALBERT BUTLER RADIO SESSION

13th year - July 29 - Aug. 12th

Courses Taught: General Theory and Code
Advanced Theory and Code
Amateur Extra Theory and Code

Golf privileges at New River Country Club; also fishing

TRULY A VACATION WITH A PURPOSE!!!

People attended from the following states and areas:

North Carolina, South Carolina, Missouri, Tennessee, Utah, Florida, Oklahoma, West Virginia, Alabama, New Hampshire, Iowa, District of Columbia, Vermont, Arizona, Indiana, Ohio, New Jersey, New York, Massachusetts, Maryland, Virginia, Illinois, Michigan, Georgia, Kansas, Mississippi, Nebraska, Maine, Kentucky, California, New Mexico, Arkansas, Texas, Wisconsin, Louisiana, Oregon, Connecticut, Minnesota, Pennsylvania.

OUT OF STATE:
Puerto Rico; Saskatchewan, Canada; Ontario, Canada; Quebec, Canada; Granada, Spain; London, England; Geneva, Switzerland; Netherland, Antilles; St. Croix, Virgin Islands

C.L. Peters, K4DNJ, *General Secretary*
Gilvin Roth Y.M.C.A., Elkin, North Carolina

Please send me the Booklet and Application Blank for the Camp Albert Butler Radio Session.

train of collisions between molecules along the path. As a molecule of atmospheric gas is perturbed by the pressure wave, it moves, striking a neighboring molecule which in turn moves and strikes another.

These infrasonic pulsations originate in the lower atmosphere (troposphere), where the molecules of gas are packed densly, so that each molecule travels a short distance before striking another (less than one millionth of an inch). As the pulsation travels upward to the ionosphere, the atmosphere thins and the molecules are farther apart. At an altitude of 125 miles; the molecules of gas are so thinly distributed that one may have to travel 1,000 ft before colliding with another. This density reduction is responsible for a 1,000 times amplification of the vertical movement of the atmosphere at ionospheric altitudes. The actual upward surge of the atmosphere (not the individual molecules, but the whole mass of air in the region affected by the acoustic pulse) is about 15 ft at cloud level and 15,000 ft in the ionosphere.

Because of the geometry of the earth's magnetic field, the electronis in the ionosphere behave differently from the neutral gases, which are unaffected by geomagnetism. South of the detection array, the atmospheric surge carries across the magnetic field lines. The neutral constituent moves upward normally, but the charged electrons are restrained by the field. Because radio signals are reflected from the electrons and not the neutral part of the ionosphere, the movement cannot be observed.

To the north, however, the atmospheric pulses move along the magnetic field lines, and the electrons easily move with it. Thus, the surge of the ionosphere can be observed by reflections from the mass movement of electrons north of the transmitter/receiver array.

Observations indicate, according to Davies, that when ionospheric responses to thunderstorms occur, the top of a cumulonimbus cloud has risen to more than 40,000 ft within 150 miles of the midpoint of the radio circuit. Such responses have been recorded on the Oklahoma paths and on paths between Long Branch, Illinois, and Boulder, Colorado.

Reporting in the Journal of Atmospheric Science (March 1971) on studies of the ionospheric responses, Davies and John E. Jones, also of NOAA's Space Environment Laboratory, cited two principal advantages of using the ionosphere to detect the pulsations generated in the troposphere: (1) the density decrease with altitude in the atmosphere provides natural amplification of the generated pulses, and (2) the atmosphere acts as a filter to remove unwanted acoustic waves. In effect, the ionosphere is a natural tuned receiver. The amplification is several hundreds to one, although interference from acoustic waves of unknown origin does occur.

On the basis of present knowledge, it is difficult to relate the ionospheric measurements directly to characteristics of the thunderstorm. As with any new technique, a considerable body of data must be gathered and time spent in analysis before the relationships are understood. A 10 to 20-year lag between a scientific discovery and its routine use is not unreasonable, according to Davies.

T.V.I. PROBLEMS?

T.V.I. Filter B & W Model 424 designed for C. B. and Ham up to 100 watts. Input & output impedance 50 ohms more than 60 db of attenuation of harmonics.

the **Incomparable CX7A**

signal/one **CX-7A**

New "A" model Now Available
Still $2195 – Great New Reliability

Quite frankly there is nothing with which to compare the CX7A. What else is there that has all modes 10 thru 160 meters with instant, no tuning band changing? With true break-in CW, a Pre I.F. noise blanker, R.F. clipping, and a built-in Keyer? With a separate receiver, wattmeter SWR meter, FSK shift, transmit offset and a freq meter digital counter?

RELIABILITY IS NOW standard equipment. Every component is instrument grade, hand-picked, and individually tested. The CX7A is American-made, "Ham" tested and "burnt-in" by Hams who build, service, and sell it.

If you want to move up to the best, phone DON PAYNE, K4ID, for personalized service, a brochure, and a KING-SIZE trade-in on your gear. It's perfection for $2195.

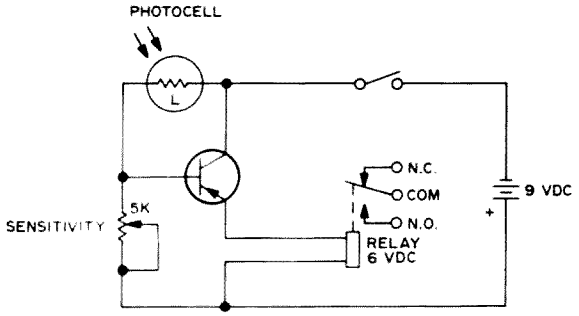
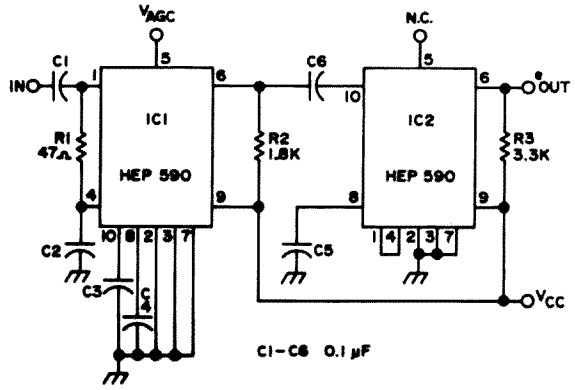
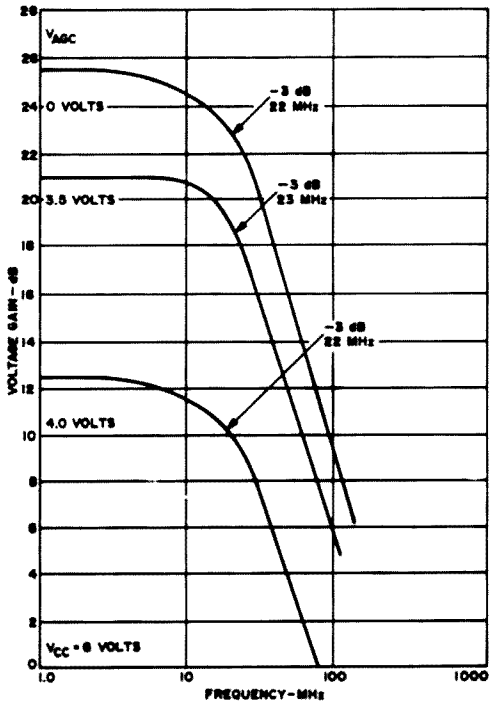
CIRCUITS, CIRCUITS, CIRCUITS...



The following circuits have appeared in the referenced books, magazines, application notes, etc. While we try to reproduce all of the information that should be needed by an experienced constructor, readers may want to avail themselves of the original sources for peace of mind.

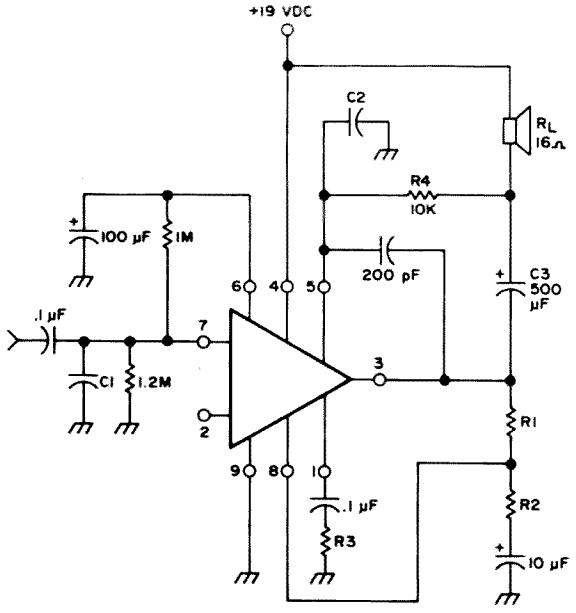
Readers are requested to pass along any interesting circuits that they discover in sources other than U.S. ham magazines. Circuits should be oriented toward amateur radio and experimentation rather than industrial or computer technology. Submit circuit with all parts values on it, a very brief explanation of the circuit and any additional parts information required, give the source and a note of permission to reprint from the copyright holder, if any, and the reward for a published circuit will be a choice of a 73 book. Send your circuits to 73 Circuits Page, 73 Magazine, Peterborough NH 03458.



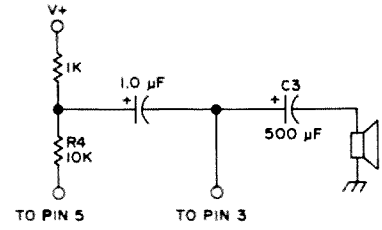


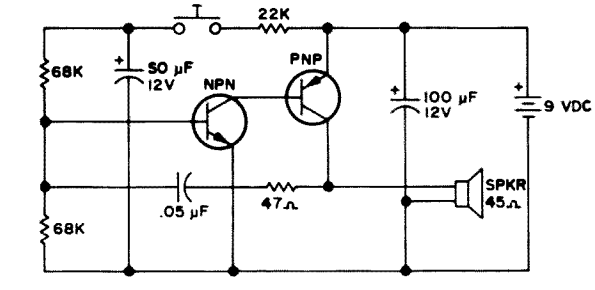
R1, R3	1.8K	
R2, R4, R5	1K	
U1	SN 7400	QUAD 2-INPUT NAND GATE
U2, U3	SN 7490	DECADE COUNTERS
Vcc	5 VDC	

This crystal calibrator has a fundamental 1 MHz crystal and its frequency is divided to give outputs of 1 MHz, 100 kHz and 10 kHz. All the parts used are easily available from Polypaks, HAL Devices, etc., for a small fee. Circuit courtesy of Zero Beat (Victoria BC) for November, 1971

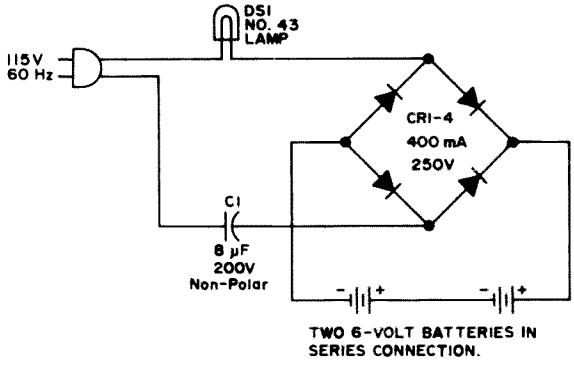


Turn anything on — or off — with light. Use it to trigger an alarm, to turn on lights at dusk, activate a counter as people pass. . .or whatever. Easy-to-build versatile circuit courtesy of Calactro Handbook. Transistor is a Calectro K4-505.





Two stage video amplifier with AGC control of IC gain and no tuned circuits required. The curve shows the video amplifier response with AGC. This circuit from Motorola HEP Radio Amateur's IC Projects HMA-36, available free from Motorola, Dept. 73, Box 20924, Phoenix AZ 85034.



SENSITIVITY FOR P_o mV	C1 pF	C2 pF	R1 k OHMS	R2 OHMS	R3 OHMS	R_L OHMS	P_o W
600	0	0	10	1.0K	82	16	2.0

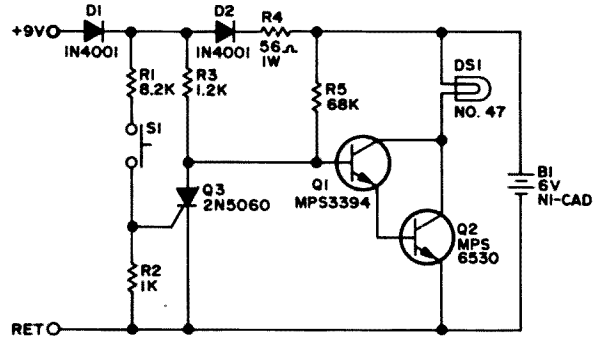
A typical circuit application utilizing a Motorola MFC9010 monolithic functional circuit, which is a 2-watt audio amplifier designed to provide the complete audio system in TV, radio and phonograph equipment. Schematic at right shows alternate connection to permit connecting speaker to ground instead of to V+. Circuit courtesy Motorola Functional Circuits handbook.



Another Calectro circuit, this one a screaming siren. Tone rises and falls like the big ones. Circuit courtesy Calectro Handbook (50¢), 400 S. Wyman, Rockford IL 61101. Q1 is a Calectro K4-506, Q2 a K4-505, S1 is a push button switch.

Simple ni-cad battery charger circuit from FM Magazine, as reprinted in The Best of FM, an anthology of articles from FM Magazine published by 73 and available from 73 Magazine, Peterborough NH for $4.95.

Audio amplifier. This circuit has a high impedance input, low current drain (0.2 mA), low impedance output, wide range (10- 30,000 Hz) and a gain of 200 to 400. Circuit courtesy Motorola HMA-33 Tips on Using FETs.

Power failure indicator. Indicates either momentary or continuous power failure. Circuit courtesy Motorola Semiconductor Power Circuits Handbook. When circuit is reset it will trickle charge the battery, keeping it at full charge.

EXTRA CLASS LICENSE STUDY GUIDE

Questions & Answers Part I

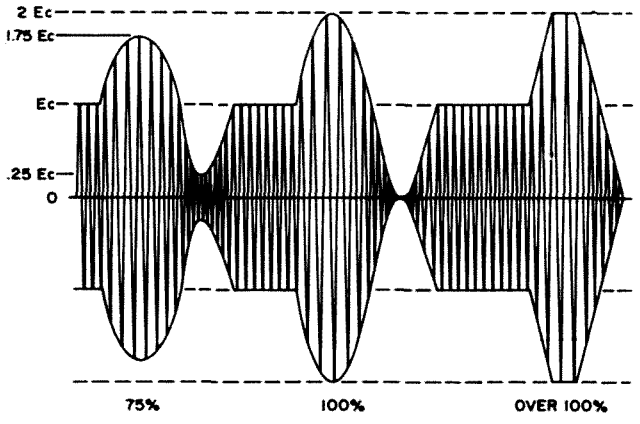
The Extra class amateur license is the highest rank of license offered, and as such demands the greatest knowledge of radio and electronics theory and practice (in fact, the Extra class exam requires at least as much knowledge as does the First Class Commercial Radiotelephone license with radar endorsement, generally accepted as being the most demanding of all FCC exams).

Because of the greater requirements of the Extra class license, its official study list of questions is the longest and most detailed of all the FCC study lists, totalling 90 questions. For comparison, the General class study list contains only 52 questions and the Advanced class has 65. What's more, the Extra class questions frequently call for detailed discussions of the subject rather than simple one-sentence replies.

Because of the greater detail and larger number of questions to be covered, we've divided the Extra Class Q&A portion of this license study course into two sections of 45 questions each. This section contains the first 45 questions, with our answers. The next one will contain the remaining questions, 46 through 90.

We must emphasize that this is merely a checklist which you may use as a "final exam" to test your readiness for the Extra class exam. Explanation of the material has been held to the mimimum; for details, refer to the Extra class study series previously published in 73 Magazine, or our reprint of the series.

1. What are sideband frequencies? During 100% sinusoidal amplitude modulation, what percentage of the average power is in the sidebands? How is the sideband power related to the percentage of modulation?



A. Sideband frequencies are those frequencies contained in the "sidebands" of a modulated signal. The sidebands consist of frequencies above and below the carrier frequency, which correspond to the sum of carrier and modulating frequency, and the difference, respectively. If the carrier is modulated by a single frequency, the side frequencies will also be single frequencies. If the carrier is modulated by a band of frequencies (as is usually the case, for voice transmission) the sum and difference signals become bands also, accompanying the carrier.

During 100% sine-wave AM, one-third of the average envelope power (total signal power) is in the sidebands and two-thirds is contained in the carrier. That is, the sidebands contain half as much power as the carrier.

Modulation percentage is based on a voltage measurement. Power varies as the square of the voltage, so the power content of the sidebands will vary between 0 and 1/3, proportionally to the percentage of modulation as it varies from 0 to 100.

2. What do the modulation envelopes of amplitude-modulated waves with 75%, 100%, and greater than 100% modulation look like?

A. Refer to Fig. 1 for views of the modulation envelopes.

3. How may a limiter be employed in an FM receiver?

A. In an FM receiver, the purpose of the limiter is to remove all amplitude variations from the received signal, thus reducing atmospheric noise (which consists primarily of AM components).

4. What precaution(s) should be taken when measuring the rectified grid voltage in an oscillator with a dc voltmeter?

A. For the protection of the voltmeter, all rf energy should be blocked from reaching the voltmeter by use of an rf choke in series with the voltmeter "hot" lead. To assure that oscillator operation suffers minimum disturbance, a high-impedance voltmeter should be used, and care should be taken to avoid introducing stray capacitance.

5. What is meant by frequency shift keying and how is it accomplished?

A. Frequency shift keying (FSK) is a form of modulation usually used in RTTY operation in which the "mark" condition is represented by a signal at one frequency and the "space" condition is represented by a signal at another frequency. One of the two signals is always present, but they are never present simultaneously.

FSK is usually accomplished by switching a small capacitance into and out of the oscillator resonator circuit, to produce the lower of the two frequencies when the capacitor is in the circuit, and the higher when it is out of the circuit. This switching is frequently accomplished by diodes.

6. Why is there a practical limit to the number of stages that can be cascaded to amplify a signal?

A. The amount of amplification which can be applied to any signal is limited by the unavoidable electrical noise introduced both by the early amplifying stages, and present with the signal when it enters the amplifier.

The final limit is reached when the noise that accompanies the signal at the input to the amplifier is the controlling factor. "Low noise" amplifiers are designed with the intent of reaching this limiting condition, and it can be reached in practice at all frequencies in normal use, from the audio range through SHF.

Certain techniques of "coherent detection" make use of a prior knowledge of the nature of the expected signal to dig into the accompanying external noise for the signal. Such techniques, for instance, make possible radar measurement of the distance from Earth to Venus, and are used in many types of communications. Even these techniques, though, are ultimately limited by the random and unpredictable nature of background noise.

7. What are A5 and F5 emissions? On what amateur frequencies can these emissions be transmitted? Can A5 emission be transmitted satisfactorily using one sideband only?

A. A5 and F5 both designate video signals; A5 means amplitude-modulated video, while F5 stands for frequency-modulated video.

Since video signals cover a bandwidth from dc up to several MHz, A5 signals are seldom satisfactory if transmitted using one sideband only, due to phase shift of the low-frequency components. To overcome this situation, yet reduce the extreme bandwidth which would otherwise be required, commercial television uses the "vestigial sideband" method to transmit by A5 signals. A vestigial-sideband signal is a normal DSB (with carrier) signal at very low frequencies, but one sideband (normally the lower one) is cut off at 750 kHz, so that at modulating or sideband fre-

quencies greater than 1.25 MHz the signal is single sideband. Between 750 and 1250 kHz, the lower sideband is rapidly attenuated. Thus a video bandwidth of 4.5 MHz is compressed into a channel only 6 MHz wide, including guard bands and audio information.

Both A5 and F5 emissions are legal on all amateur bands above 420 MHz.

8. How does amateur TVI usually affect television reception?

A. Alarmingly. The interference may manifest itself in any of a number of ways. Either the audio or the video parts of the TV signal, or both, may be affected.

If audio is affected, the TV viewer usually hears a distorted version of the amateur's transmissions. This is usually due to audio rectification, the same action which affects hi-fi and stereo sets, BC radios, hearing aids, etc.

Effects on the video may be varied. If a beat between the amateur's signal and the TV signal occurs, a cross-hatching may appear on the screen. If the beat frequency is low, this may show up as vertical bars across the picture. If the beat is high in frequency, it may be cross-hatching or simply a "grainy" appearance.

In severe cases, TV reception may simply be blotted out due to overload of the TV-set front end.

Video interference due to the amateur's audio modulation usually shows up as flickering horizontal bars of dark and light. This is true if the amateur uses AM. With FM, a cross-hatching which flickers in step with the audio occurs.

Cross-modulation interference may cause the sound of a local FM station to appear in place of the TV channel's sound, and it's possible for all these effects to occur at the same time (though highly unlikely).

9. Describe briefly the basic sections of a single sideband (SSB) transmitter. In what section of a properly operating SSB transmitting system is distortion most likely to originate? In what section is nonlinearity most likely to originate?

A. The basic sections of an SSB transmitter are the audio and sideband generation portion, the frequency control portion, and the power amplifier. The audio portion restricts audio from the microphone to the frequency range necessary for effective communication, and the sideband generator translates the frequency spectrum of the speech from the audio range into radio frequency (usually at some fixed frequency, to facilitate separation of the desired sideband). The frequency control portion translates the SSB output of the sideband generator into an SSB signal at the desired output frequency, and the power amplifier brings the signal's power level up to the desired point for radiation.

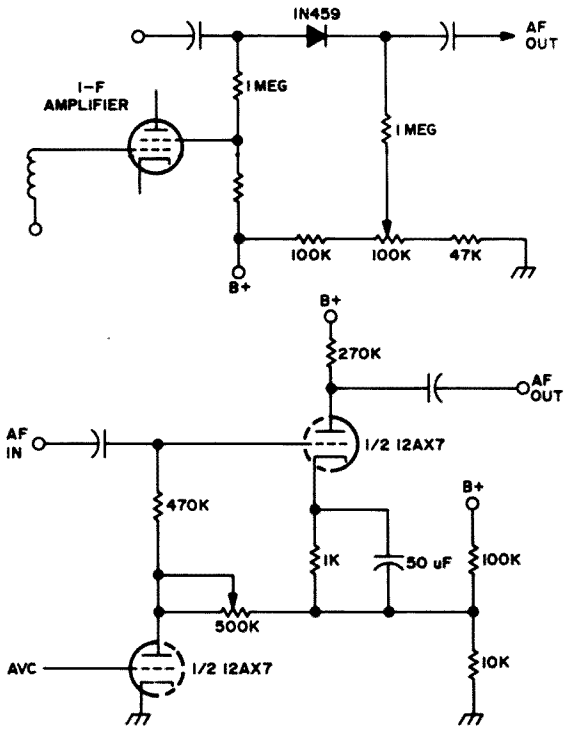
Distortion most usually occurs in the power amplifier portion of the transmitter. Nonlinearity, being a specific form of distortion, also is most likely to occur in the power amplifier, but may occur at any point within the transmitter. Once it occurs, it cannot be removed from the signal.

10. Define what is meant by the time constant in a resistance-capacitance circuit? How is the time constant determined?

A. The time constant is a measure of the speed with which the ciruit can react to step-impulse stimuli, and is a function of the product of resistance and capacitance in the circuit.

Time constant is determined by multiplying the resistance in ohms times the capacitance in farads, with the result being expressed in seconds. In practice, megohms and microfarads are the units usually used, with the result still coming out in seconds.

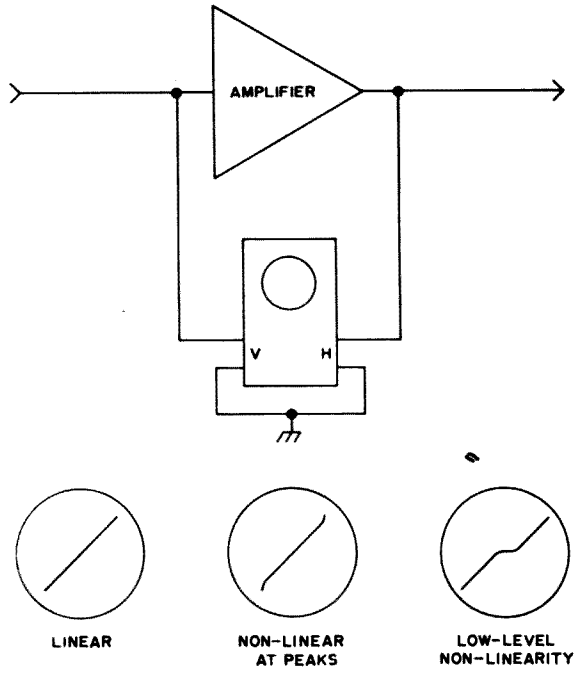
Time constant is sometimes defined as the time taken by the capacitor to reach 63% of full charge, through the resistance, and sometimes as the time taken by the capacitor to discharge to 37% of its original charge through the resistance. Both these definitions are accurate although incomplete.



As a working rule of thumb, an RC circuit will be essentially fully charged (or discharged, as the case may be) within 5 time constants, although in theory full charge or total discharge cannot ever be attained.

11. How does a squelch circuit operate? Draw a commonly used squelch circuit.

A. A squelch circuit acts to silence the audio output of a receiver in the absence of

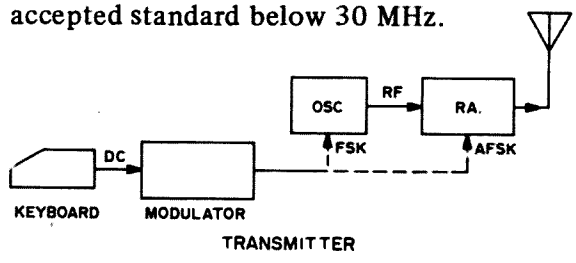


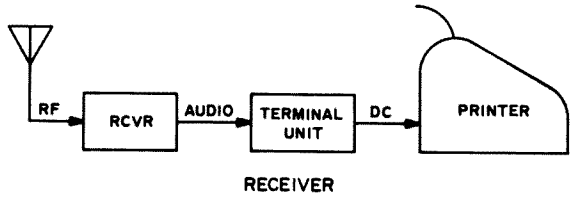
an incoming signal. Most often, the circuit either opens or shorts out the receiver's audio, between detector and audio amplifier, under control of a dc level obtained from the carrier of an incoming signal (usually the avc voltage). Some circuits, however, make use of "between-station hiss" to actuate the squelch.

Figure shows two typical squelch circuits, both operated from the avc line. When an incoming carrier causes an increase in avc level (more negative), the squelch circuit permits audio to pass through to the receiver's output.

12. An oscilloscope is used to study the relationship between the input and output of an amplifier produced by a voice signal. How would the scope pattern display a linear relationship between the input and output signals?

A. If the scope is hooked up as shown in Fig. , to directly compare input and output signals, a linear relationship would be indicated by a perfectly straight line on the face of the CRT. Any curvature in the CRT display would indicate loss of linearity at that point of the signal.





13. Draw a block diagram of an RTTY system showing the primary function of each stage. What is the proper way of identifying an RTTY transmission? What is the most widely used frequency difference between the mark and space frequencies in a conventional RTTY transmitter?

A. See Fig. for required block diagram.

An RTTY transmission should be identified by means of CW, as well as by transmission of all required information in the international teleprinter code.

The most widely used frequency shift is 850 Hz with 170 Hz rapidly becoming the accepted standard below 30 MHz.

14. How can the two-tone test output of a linear amplifier be used to tell if a transmitter is working properly? Show scope patterns for optimum, overdriven, and underdriven amplifier conditions.

A. The scope patterns produced by the two-tone test can be used to determine the audio input level at which peak flattening occurs in the output signal as shown in Fig. (in Fig. , the "optimum" condition is just prior to the point at which peak flattening begins to occur).

Some additional information may be obtained from a modulation-envelope display of the two-tone test, but it is highly subjective. More accurate data on transmitter working conditions is obtained from the "bow-tie" display. In this pattern, curvature of the sloping sides indicates nonlinearity. Flattening of the tips of the pattern indicates overdrive. With proper bias conditions, the crossover will be sharply defined; if bias adjustments are incorrect, curvature will occur near the crossover point although the remainder of the pattern may indicate perfect linearity.

15. Define the alpha cut-off frequency of a transistor. How is this parameter of use in circuit design?

A. The alpha cut-off frequency is that frequency at which "alpha" (common-base current gain) of the transistor drops to 71% (3 dB down) of its value at "low frequency" (normally 1 kHz). In other words, it is a measure of the high-frequency performance of the transistor.

Alpha cut-off frequency has little application to current circuit design, because the common-emitter circuit is more commonly used. It is, however, usually higher than the corresponding cut-off frequency for common-emitter circuits, and indicates the maximum frequency at which the transistor may be useful in amplifier, oscillator, and switching circuits. Normally, a transistor will oscillate readily at its alpha cut-off frequency, but may not function properly as an amplifier at this frequency.

16. What are inductive and capacitive reactance? How are their phase angles related? How does their reactance affect actual power dissipation in a circuit?

A. Reactance is a measure of the opposition to flow of alternating current. Inductive reactance is a measure of the opposition offered ac by an inductor, while capacitive reactance measures the opposition offered by a capacitance. Unlike resistance, reactance dissipates no power, but merely shifts the phase of current with respect to voltage, thus making a part of the power unavailable for dissipation.

Pure reactance of either type shifts phase by 90 degrees. With inductive reactance, the current lags the voltage by 90 degrees, and with capacitive reactance, the voltage lags 90 degrees behind the current.

In a circuit containing both reactance and resistance, only the resistance dissipates power. The power dissipation is reduced by presence of the reactance, because it makes a portion of the available power unavailable to the resistance.

Inductive reactance increases with frequency, while capactive reactance decreases with frequency. Thus at dc, an inductor is a short circuit while a capacitor is an open circuit, and at "infinite" frequency, the roles are reversed.

17. How does the positioning of a powdered iron tuning slug affect the frequency of the oscillator it is tuning?

A. Since the powdered iron slug has higher permeability than does air, as the slug moves into the coil it increases the inductance and thus lowers the frequency of the oscillator.

Brass has lower permeability than air, and is sometimes used for tuning slugs. When a brass slug is used, inductance decreases and frequency rises as the slug is inserted into the coil.

18. Define the deviation ratio in a frequency modulated signal.

A. Deviation or "swing" is the difference between the apparent instantaneous frequency of the modulated-signal envelope and that of the carrier. Deviation ratio is the ratio between deviation and the frequency of the modulating signal. Strictly speaking, it is the ratio between maximum deviation, and the maximum modulating frequency. In an amateur NBFM signal below 52.5 MHz, with maximum modulating frequency of 3 kHz, deviation ratio is not legally permitted to exceed 1.0.

19. What type of signal will be produced when the output of a reactance modulator is coupled to a Hartley oscillator and multiplied in frequency?

A. FM.

20. How would the reception of a single sideband signal be affected if the carrier is not completely suppressed? How can spurious signals in the output of the mixer stage of an SSB transmitter be suppressed?

A. The incompletely suppressed carrier may produce a beat frequency with the receiver's bfo if tuning is not exact. This beat appears as a low-pitched "growl," and may vary slightly in frequency as propagation effects shift the frequency of the incoming signal, or the bfo shifts slightly. In addition, the carrier may cause interference to other signals.

Spurious signals in the output of the mixer stage can be suppressed by proper design, by choosing input frequencies so that no mixer products except the desired one fall within the range of the output tuning circuits, and by the use of many selective tuned circuits between mixer and antenna. High-level mixers are to be avoided in the interest of suppression of spurious signals. . . .Staff

The Poorer But Wiser Ham's FM Base Station

By this time FM is clearly here to stay and the confirmed FM addict wants at least a mobile and a base station, if not a walkie-talkie as well. The older, tube-type, commercial sets, although obsolete for their original intended purpose, offer the ham excellent sensitivity, power, and stability, and unless they are positively ancient, they offer a narrow passband as well. The latter is advantageous when you are digging for weak stations, assuming they are on frequency.

Since most of the commercial gear was mobile (there being as many as fifty mobile units for a single base station in some installations) it follows that an obsolete mobile unit is the cheapest and most available rig today. While much of this is hard to modernize into useable mobile material, all of it is easy to rebuild into base stations.

Now, as in other branches of the ham art, you will have to do a little extra work if you want to save extra money. For instance, as with the old recipe for bear steak that starts "first catch a bear," you must first find an old radio. This is easier to do than you might think just from reading the magazine ads, because the prices which the General Electric Pre-Progs, Motorola 80 D's, and similar rigs bring do not justify advertising them. However, find a firm that advertises more recent gear, write them or drop in at their warehouse and you will usually find the older, cheaper gear there and sometimes almost for the asking. Another good method is to have a friend inquire over the air, or check the goodie-row offerings at your nearest hamfest. At one last month, I bought a good Link 1905 receiver for $1. With $1.60 for two crystals from JAN and odd parts from my well-stocked junk box, it is now a serviceable 76–94 monitor receiver sitting in my bedroom. This is admittedly a better than average bargain, but you will be astonished at how much radio you can buy for how little if you go back about two model styles. I have bought working sets for $40 and you-fix-its for $5. See page 50, July, 71, issue of *73* for a representative list of dealers, or leaf through any current copy for others. If they advertise current type-accepted commercial FM gear, they probably have the less expensive earlier stuff, also.

There is no problem at all in getting circuit information and specifications for ordering crystals if you use either General Electric or Motorola gear, as there are books of prints advertised in the ham magazines nearly every issue. If you play with Link, RCA, Bendix, and some of the others, you may have to canvass the local ham fraternity for circuit data, but most hams will cheerfully let you Xerox any prints or instruction books they have, so do not fear the other makes, just prepare to do your homework if you use them.

Possibly the best buy is the GE Pre-Progress line (ES 12, etc.). These were six-volt units to begin with, although some were modernized in various ways to 12. Later models came in original 12 volt condition, but this is not really an advantage when you decide to convert to 110 ac, and you might save money as well as work by buying a six-volt model.

The advantage, other than cost, of the six-volt models is that the filaments are all in parallel. Whereas the original tube line-up employed low current tubes wherever possible (6BH6, 6BJ6, etc.) if you have a parallel filament circuit, you can substitute other tubes for increased gain, or just because they are more available. In the 12 volt versions, you must be sure the filament currents match properly on each side of the string or some tubes will be starved while others are over-fed. In addition to risking early tube burnout, such discrepancies can

do strange things to stage gain which will be hard to find.

The first thing to do is separate out the leads which must be fed low voltage dc, such as the relays, and those which can use ac, such as the filaments. A choice is available in supplying the high voltage, as follows: You can pull the vibrator out, feed low voltage ac to the old vibrator transformer primaries, and diode-rectify the secondaries. However, you will recall that the vibrator transformers expected 120 Hz ac from the vibrators, and used a divided primary. If you run 6 volts ac to half the primary, you will come up with about the right secondary voltage, but the transformer may become too warm. This varies from model to model and from make to make. The Link 1905-1906 series had husky transformers that run barely warm this way, but the GE rigs were engineered fairly close and run warm, while some other makes will actually burn up. However, if you have the ac in sufficient quantity to feed them (6 volts at up to 30 amps!) you can easily try this method and see whether the vibrator transformers will handle it. If they do, you are home free, or almost so. You still must supply dc to the relays, and the easiest way is to use a bridge rectifier across a filament winding, if it is not grounded. A separate low-current filament transformer may be required. With such a bridge rectifier, you may need no filtering. If you use a half wave across the regular grounded filament winding, you will need beaucoup capacity to keep the relay from chattering, but either method works.

There is a power limitation in using the old vibrator transformers as described. The GE Pre-Progs, for example, used two transformers, one for low voltage and the other only for plate voltage for the 2E26 final. The rig was planned for 7–10 watts output and that is about all that little transformer can produce. It does not help much to bridge it, because the increased current drawn will drop the voltage so that you are back about where you started. However, this rig can readily be "high-powered" if you build a new high voltage supply operating directly from the ac mains. To do this most easily, you pull out the old vibrator sockets and their transformers, leaving the electrolytic cans, as they will serve in the new supply. Either on the chassis, if you pick the right size, or somewhere else, you mount a TV transformer and bridge rectify it for the final plate supply, using the center tap for the general low voltage supply for the rest of the rig. FM transmitters do not require nearly as good filtering as do AM or sideband gear, so you need only add a new 8μF 1,000 volt oil filled paper capacitor for the final plate supply.

Since you will be using about double the old plate voltage, you might as well substitute a 6146 for the 2E26 and get the added wallop it can produce. Some Motorolas used two 2E26's and you can plug in two 6146's in place of them directly. If you try this on the GE ES16, you will find that the sockets are too close together. Take heart. Simply remove the metal shields from the bottom of the tubes (carefully!) and then file a flat side on each tube base where they would otherwise touch. (One tube will be for the right hand side and the other for the left hand side, not interchangeable.)

On any such gear, inspect the high voltage bypass capacitors closely, because most of them will not stand doubling the ratings, as we are now doing. Be sure also that any dropping networks deriving voltage from the final high voltage supply are correctly reengineered. On most sets, this latter is unnecessary as the manufacturers did not want to waste any more power than they had to waste, and so the high voltage supply (vibrator or dynamotor) delivered only its full output to one terminal.

This may sound like a lot of work, but actually it should take only a few evenings, even if you have never done it before. The result will be a high quality signal at good power and minimum cost. With crystals, the new power supply components, and the usual number of tubes and other repair parts, it should never exceed $75, but don't judge it only by the present cost. Remember, this old mobile junk originally cost upwards of $1,000!

One of the happiest accidents about the Pre-Prog receivers is that while they were originally designed for wide-band reception, the loading on the i-f coils is such that if you merely peak every coil precisely on frequen-

cy ("Christmas tree them") you will achieve a pass band about 15 kHz overall which is highly compatible with modern narrow-band equipment. The overall gain, of course, improves in this process and the receivers are quite satisfactory without additional pre-amplification, although putting a good transistor preamp ahead of them makes them as hot as you could possibly want. Originally rated at .6μV for 20 dB of quieting, when the i-f strip was stagger-tuned to 120 kHz wide band service, returning brings most of them to .5 or better, and a pre-amp drops them to .2 or .3. The squelch action is uniformly good.

One additional modification which I heartily recommend, but which is certainly optional, is junking the typical carbon mike in favor of a reluctance, ceramic, or other better-sounding type. If you rework a Pre-Prog in this way, you can get an added advantage of a well compressed audio signal as well. Remove the mike transformer and you will find that the hole in the chassis exactly fits a 9 pin socket. Wire a two-stage triode amplifier here, using a 12AT7 or equivalent, and feed the resulting signal to the existing audio tube, just as if it were coming from the secondary of the mike transformer. The easiest way to do this is with a 9 pin Vector socket, so the two entire stages can be built externally and then just set in place. It does require a special shield that mounts on top of the chassis, but I always use a 35mm film can instead, because they are more available (punch holes in it for ventilation!).

This will now drive the modulator tube into compression, and when you set the deviation control to the proper point, you will have a high-average, or loud-sounding, though narrow, signal. The gain required of the first stage depends on the mike, so try a 12AX7 and a 12AU7 in the socket before you quit, and select the one that gets you the best on-the-air reports. . . .WA4UZM

AUDIO CW FILTER
Active filter with 750 Hz center frequency and band pass of 200 Hz.
Deluxe model with cabinet $20.00
Basic, without cabinet $16.00
POWER SUPPLIES
12 volts @ 5 amps. I.C. regulated to 1% of output and short circuit protected.
PS-125 ..... $40.00
Custom supplies to your specifications. Write for quote.
QRP TRANSMITTER
80 or 40 meter transistor transmitter. Completely wired and tested. Operate from 6-18 VDC, but best on 12 VDC. Great for low power C.W. Cabinet not supplied.
QX-1 (500 mw input) $5.00
2 METER FM POWER AMPLIFIER
5-10 watts input gives 15 to 35 output @ 13.5 VDC automatic transmit-receive relay. Unit will operate on 11-15 VDC.
FM-1 ..... $65.00
Terms: Send check or money order. Add $1.00 for postage and handling. Allow one week for shipment after receipt of order.

73 Magazine is published monthly by 73, Inc., Peterborough, New Hampshire 03458. Subscription rates are $6 for one year in North America and U.S. Zip Code areas overseas. $7 per year elsewhere. Two years $11 in U.S. and $12 overseas. Three years $15, and $16 overseas. Second class postage paid at Peterborough NH, and at additional mailing offices. Printed at Menasha, Wisconsin 54952 U.S.A. *Entire contents copyright 1972 by 73 Inc., Peterborough NH 03458.* *Phone: 603-924-3873.* *Say, don't forget that little old tour of Europe this fall. You'll enjoy it a lot more amid cohorts who speak your own language, and you'll love meeting the European amateurs. Also, if you are within driving distance of FM West in Fresno on June 2, say hello to Wayne. He'll be there, working hard on the fight to save the 220 band from the chaos of 27 MHz. In May Wayne will be on from Navassa with the Atlanta gang as KC4DX, so don't miss that DXpedition. In June Wayne expects to be visiting Jordan again for a follow-up on his 1970 visit. In October it looks as if 73 will be exhibiting at the Hudson Convention for the first time in years . . . ! Keep the faith.*

Amateur Radio

MAY MCMLXXII Monthly Ha

AMATEUR RADIO WEEK PROCLAIMED

Mayor Walter Taylor, Englewood NJ signs a proclamation declaring June 18 to June 24 as Amateur Radio Week. Watching Mayor Taylor are WA2RIN, WA2NVG, and WA2CCF.

'72 ARMED FORCES DAY COMMUNICATIONS TESTS

Each year, on the third Saturday in May, the Department of Defense sponsors the observance of Armed Forces Day. This year's observance, the 23rd, will be held on Saturday, May 20, 1972. As in past years, as one of the many Armed Forces Day Programs and in recognition of the radio amateur's contributions to the field of communications, emergency services, and maintenance of morale among servicemen , the Departments of the Army, Navy and Air Force will conduct radio communication tests. These tests are designed to be a tangible demonstration of the firm and long-standing Department of Defense policy to encourage and support amateur radio activity.

The communication tests will consist of military-to-amateur crossband operations, using continuous wave (CW), voice (SSB) and radioteletypewriter (RTTY) modes of operation and "CW" and "RTTY" receiving tests. Special QSL cards confirming crossband communications will be forwarded to those amateurs who establish two-way contact with participating military stations.

A CW receiving test will be conducted for any person capable of copying International Morse Code at 25 words per minute. The CW broadcast will consist of a special Armed Forces Day message from the Secretary of Defense addressed to all radio amateurs and other participants.

A RTTY receiving test will be conducted for any station possessing the required equipment. This is a test of the operator's technical skill in aligning and adjusting his equipment, and serves to demonstrate the growing number of amateurs becoming skilled in this method of rapid communications. The RTTY broadcast will consist of a special Armed Forces Day message from the Secretary of Defense to all radioteletypewriter enthusiasts. The message will be transmitted at 60 words per minute.

HAMS PROVIDE LINK TO W.VA. FLOOD AREA

Reprinted from the Wheeling News Register, March 6, 1972.

As the death toll mounts and hope for the survival of the missing fades, amateur radio operators manning emergency communications in the Logan County disaster area are called to check the official death list with increasing frequency.

Since the Buffalo Hollow Creek flood tragedy 10 days ago, hundreds of ham radio operators have assisted in maintaining a precarious communications link with the devastated area and the outside world.

For C. W. "Gibby" Welsh of McMechen, ham radio operator since 1931, his kitchen-side radio room has been a front row seat on the disaster. He and his wife, appalled by the magnitude of the tragedy, marvel at the fortitude and perseverance of radio operators in keeping the air waves open 24 hours a day since the wall of water swept through the mining camp-dotted valley.

Within hours after the flood, a radio operator in Mallory, W. Va., two miles below Man on Buffalo Creek, sent out the first eye-witness reports of survivors, Welsh says. He stayed on the job for days until a net control was designated by the West Virginia Emergency Network.

Today station W8ETF in St. Albans, W. Va., is still receiving messages from friends and relatives of Buffalo Creek residents seeking news of their health and welfare.

Expressing his pride in the devoted service provided by the amateur radio operators, Welsh reports hearing of hundreds who volunteered their service during the ordeal since the flood. He isn't surprised, though, because ham radio operators have traditionally provided people-to-people contact throughout the world in time of need. The circle of friends ham operators acquire around the globe cover the world. Generally the contacts radio operators make are on a strictly for friendship basis. But when disaster strikes, they fill the breech left by downed telephone lines and washed out roads or more often supply the communications link where no other exists.

"If everyone was an amateur radio operator, this would be a more peaceful world," says Gibby Welsh. In the meantime, everyone can share in the pride Welsh feels for the tremendous job being done by West Virginia's ham radio operators.

Relayed by Fred McGee, Moundsville, WV.

ANTARCTIC DRAMA
HAM HELPS SAVE PLANES

On 28 February at 6:55 PST, amateur radio operator W6AJZ, Peter Lovelock, of Santa Monica, responded to an emergency call from KC4USP, National Science Foundation Radio at Palmer Station, Antarctica.

KC4USP reported that two Navy aircraft returning to Christchurch, New Zealand due to bad weather, were short of fuel and unlikely to make their destination. Due to abnormal radio conditions, Palmer Station was unable to make radio contact with Christchurch. W6AJZ responded to a call for help and was requested to phone Commander Osborne, Miami, Florida, and have him notify Christchurch by commercial communications that both aircraft were attempting alternate landing at Dunedin, New Zealand. It was urgently required that this airport implement emergency conditions including turning on all landing lights, field lights and adjacent city lighting to guide the troubled aircraft.

Apprised of the situation, Commander Osborne contacted Washington. Telephone contact with W6AJZ was then transferred to Captain Price-Lewis in Washington, where communications were already established with Christchurch. For the next 45 minutes all communications between Palmer Station and Washington/Christchurch were relayed via W6AJZ.

During this period Palmer reported radio contact had been lost with one of the aircraft. The aircraft's last known position was relayed to Washington and Christchurch. The commanding officer of Palmer Station declared a May-Day status.

Captain Lewis reported, for relay to Palmer, that all required emergency measures had been implemented at Dunedin Airport, and that air-sea rescue facilities on the South Island had been alerted. At 7:50 PST, with all emergency preparations in New Zealand confirmed by Captain Lewis, emergency radio contact with KC4USP and landline to Washington was secured.

Later that day Captain Lewis telephoned W6AJZ to advise that both aircraft had landed safely. A letter of March 3 from the National Science Foundation confirmed the safe return of the two Navy LC-130 transport aircraft with the assist of amateur radio communications.

Banned Countries List: Cyprus (amateur operations suspended except for operation on special occasions when call sign 5B4 will be used and communication with other countries is permitted), Gabon, Iraq, Khmer Republic (formerly Cambodia), Libya, Pakistan, Turkey, Yemen (Peoples Democratic Republic - formerly Southern Yemen) and Viet-Nam.

Third Party Traffic Agreements: Amateurs of Canada may exchange Third Party communications with the amateurs of the following countries: Bolivia, Chile, Costa Rica, Dominican Republic, El Salvador, Honduras, Israel, Mexico, Peru, U.S.A. (Territories and Possessions), Venezuela. Effective 12 March 1972: Trinidad and Tobago.

Reciprocal Licensing Agreements: All Commonwealth countries are eligible for reciprocal amateur operating privileges unless evidence that a country does not grant reciprocal operating privileges to Canadian amateurs. Canada also recognizes such agreements with the following countries: Belgium, Dominica, Dominican Republic, Ecuador, France, Fed. Rep. of Germany, Israel, Luxembourg, Mexico Netherlands, Nicaragua, Norway, Peru, Portugal, Rep. of Panama, Senegal, Sweden, Switzerland, U.S.A., Uruguay, and Venezuela.

SKYLARC PROPOSAL TURNED DOWN

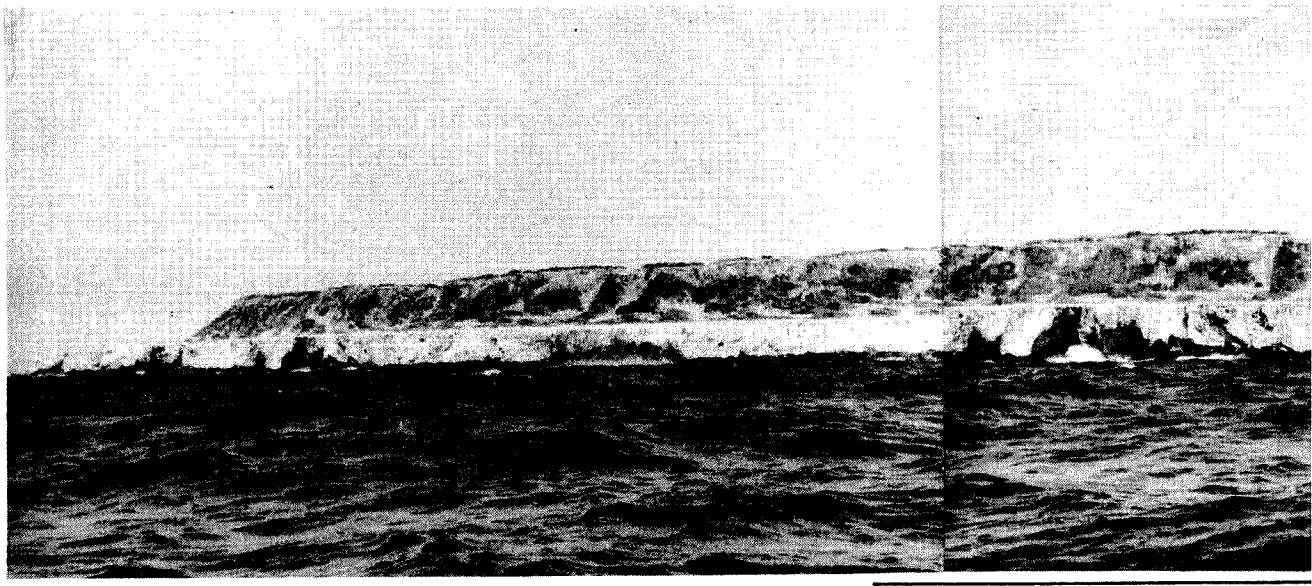
The following letter was received recently from NASA concerning AMSAT's proposal to provide a ten-meter amateur station for NASA's SKYLAB manned orbiting laboratory scheduled for flight in 1973:

Dear Mr. Klein:

As you know, the AMSAT proposal to provide a radio amateur communications package for leisure time use by the crew on Skylab has been the subject of serious consideration within the Skylab Program for some time now, and more recently, by the top management of NASA.

It is with real regret that I must inform you that in spite of the broad appeal of your concept and a generally favorable disposition to encourage AMSAT activities, NASA has concluded that we cannot add it to Skylab at this stage of the program; and, therefore, we must reject your proposal.

The decision involved many factors difficult to summarize briefly, including concerns for the priority of this proposal relative to other program additions that are also under consideration, the funds for the necessary integration and testing, and concerns for even a small additional diversion of management and engineering attention at a critical time in an extremely complicated program.



Our conclusion was not an easy one to reach. Considered by itself the proposal appeared feasible and reasonable - one that we could not reject out of hand. It may be of some solace to you that I brought the subject to the attention of Dr. Fletcher (NASA Administrator) and Dr. Low (Deputy Administrator) because of the uniqueness of the proposal and that the final decision was made by them, and then only with reluctance.

Should you desire, Mr. William Schneider, Director, Skylab Program, would be pleased to give you a more complete debriefing on our decision.

Sincerely,

Dale D. Myers
Associated Administrator
for Manned Space Flight

73 GOES TO NAVASSA

One of the rarer spots in the world of the DXer is a little deserted island in the Caribbean not far from the stronghold of Papa Doc Junior . . . indeed the island, though it actually belongs to the United States, is claimed by Haiti. This erstwhile German prison island has been off-limits to everyone up until just recently, ever since the late 50's.

A group of Atlanta amateurs have organized an expedition to put Navassa on the air for three days in mid-May and have asked Editor-Publisher Wayne Green W2NSD to join the group. Permission has been obtained from the Coast Guard and the FCC has issued a special events call for the trip of KC4DX. The last call assigned for Navassa was issued to Wayne back in 1958 and was KC4AF. Wayne and five other amateurs visited the island at that time and in four days of around the clock operating rendered it un-rare for DXers.

You may be sure that the DXers will be reading the details of this exciting trip in 73, where it will be reported in full.

It is hoped that financial support will be obtained for a professional film of the expedition. Dave Bell, who produced the Hams Wide World film is interested in the project, and at least two major manufacturers have indicated an interest in the film.

Landing site at Navassa.

CW AWARD

To promote CW activity on six meters, Dennis McCormack, K1PLX, is awarding a special certificate to stations that work ten or more stations on CW or MCW. This is a great way for Technicians to improve their code while preparing for the General Class exam. Why not have a certificate that shows you operate this fun mode? It is a nice sign of accomplishment for anyone who operates six meters. The award is available for only a quarter in stamps, IRC, or cash from D. McCormack, K1PLX, $$2, Box 329, Salem NH 03079. There are eleven different types of endorsements too.

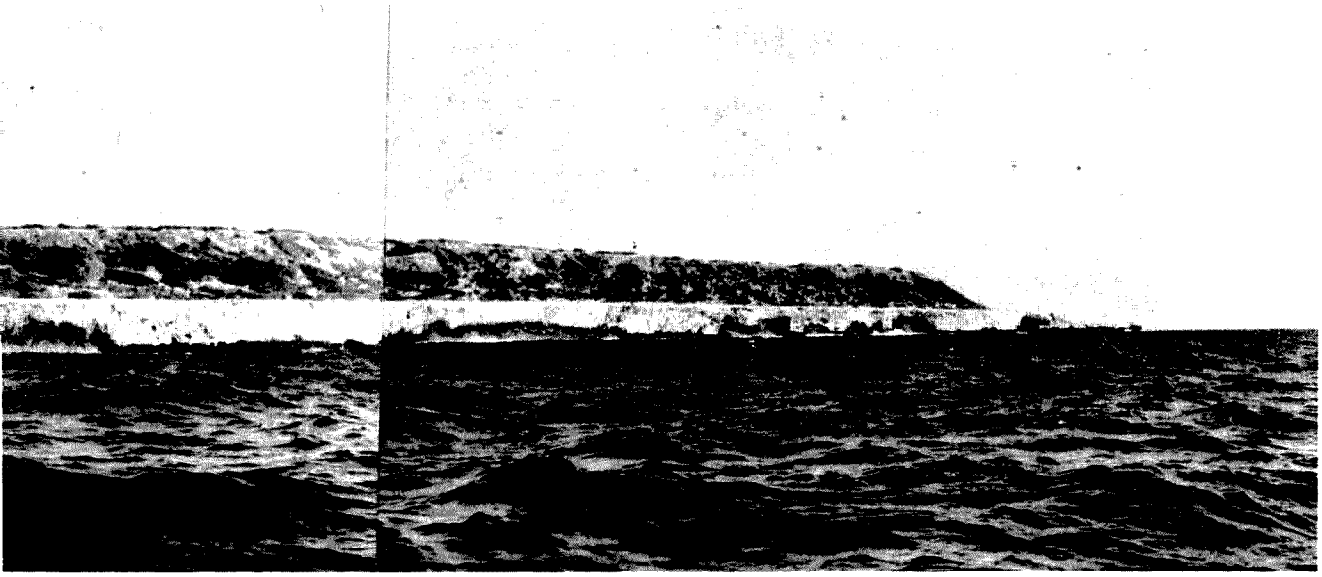
FLASH!

New OSCAR 6 Development



AMSAT has just announced that the OSCAR 6 active relay satellite 2 to 10 meter translator would operate in the non-inverting frequency mode. The launch is scheduled for July. The input transponder frequency range on 2 meters is from 145.90 to 146.00 MHz. The transponder output on 10 meters is from 29.45 to 29.55 MHz. The exact 10 meter output frequency can be calculated by subtracting 116.45 MHz from the 2 meter input frequency. Of course the output frequency can be plus or minus about .7 kHz due to Doppler shift on both the input and output frequencies. Manual 10 meter receiver tracking will be necessary on all modes except FM where AFC or a Phase locked Loop detector can be utilized. An example of the frequency translation is that if OSCAR 6 receives a 145.950 MHz input signal on 2 meters then the translator output frequency on 10 meters would be 29.500 MHz plus or minus the combined 2 and 10 meter Doppler shifts.

Horizontal linear polarization will be used on both the 2 and 10 meter antennas on the OSCAR 6 satellite.

SCHOLARSHIP ANNOUNCED

The Foundation for Amateur Radio, Inc., announces the annual award of the John Gore Memorial Scholarship for either graduate or undergraduate study. The Scholarship pays $500 for the academic year. Upon re-application, it is subject to being renewed for succeeding years.

Licensed radio amateurs who intend making a career in electronics or related sciences may now request the application for the academis year 1972–1973. Requests should be addressed to the Chairman, Scholarship Committee, 8101 Hampden Lane, Bethesda, Maryland, 20014. Requests for applications must be postmarked prior to May 31, 1972.

OBSERVATIONS ON THE SPACE CONFERENCE

Gary Allsman, W5UEW

Recently I had the opportunity to observe the amateur radio fraternity and one facet of its work from a position that not many of us from the hinterland, West Texas, often have the opportunity to do. I was fortunate to be in a position to take part in the preparation for and participate in the 1971 World Administrative Radio Conference for Space Telecommunications, WARC-ST, held this last summer in Geneva and thought the following comments would be appropriate on the eve of the A-O-C launch:

The Amateur-Satellite Service came out fairly well at the WARC-ST but things could have been better. And as one might expect, favorable amateur influence in a large number of delegations could have been greater.

The IARU, with AMSAT providing technical support, was present as official observers and carried the ball for the amateur community so far as on scene support was concerned. The IARU was highly respected by all delegations and provided a strong and necessary favorable influence for amateur matters at the Conference. (As a side light, some organization like the IARU must be on hand as a politically neutral source of information; often information from national delegations is looked upon as colored by national interests.)

But IARU presence at the Conference was not enough. A large majority of delegations come to a conference with a predetermined opinion on matters involving policy or politics in contrast to matters involving technical trade-offs. Amateur radio unfortunately often falls in the former category. This means the amateurs in each country must work to convince their own telecommunications officials to look favorably toward amateur matters before a conference begins. At a WARC each country has one vote and the favorable vote of just 8 or 9 additional countries at the Conference could have resulted in additional allocations for the Amateur-Satellite Service.

There is insufficient space here to try to categorize the various reasons why an administration comes to a conference with preconceived negative positions toward amateur radio. In a few smaller countries however these negative positions are often based on one or two negative encounters with individual amateurs or sometimes just a complete misunderstanding of what amateur radio really means and tries to do.

The activities of AMSAT provide new opportunities to educate high officials and provide favorable public relations. Possibly the glamour of space will open new doors and we can swing the telecommunications authorities in more countries around to see the advantages of making all aspects of amateur radio available to their citizens.

Reprinted from AMSAT Newsletter.

CW DX MOBILE

Congratulations to W6AM, Don, who has worked 176 countries from his mobile station during normal to and from work driving, about one hour per day average. He runs 1 KW on CW in the mobile.

NEW PRODUCTS

New Alignment Tool Set

FMers and hams who just cannot find the right alignment tool now can keep all of these valuable instruments in one place. Jensen Tools and Alloys has come frequencies involved. Most receivers use interchangeable 45 MHz crystals, the tools for ham and other communications services. All are insulated and they include a long-reach core aligner, i-f transformer aligner, some special TV aligning rods, slotted tip, recessed tip, and hex style tips are all included. The pouch rolls up neatly and folds over so the tools can never fall out to be stepped on and broken. Under $17, it is available from *Jensen Tools and Alloys, 4117 N. 44th St., Phoenix AZ 85018.*

Mobile Antenna Gutter Mount

Here's new convenience in a rugged, all stainless mobile antenna gutter mount. The unit installs quickly with only a screw driver, is self-grounding and no holes are required in the auto body. Surprising signal results are received using a small spring and resonator only mounted on the 3/8-24 stud – no mast section is required. Also, it is easy to reach out the window and pull down the antenna for garages and other obstructions.

Add a small protective strip under the clamp screws and the bracket becomes a very strong trunk lid mount! When used with small transceivers (cigarette lighter plug-in) you can be mobiling in any car or truck in a very few minutes.

Priced at $7.95, it is available from *Rejsa Engineering Co., 7632 Plymouth Ave. N., Minneapolis, MN 55427.* (Spring, resonator and coax not included.)

LETTERS

I wholeheartedly agree with the idea of using 146.52 as a simplex channel and will do all I can to promote 52 as suggested.

Ron WA1PMS
Arrow Electronics
Norwalk CT

Following is a letter to the editor of the LIMARC Log:

Dear Ed:

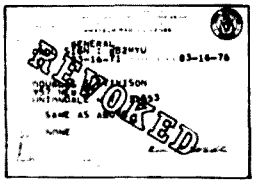
On Thursday, Jan. 13, I was in Dayton Ohio with my TR-22 and I had the pleasure of participating in a ham radio function that was unique in my (too many) years of experience. I think LIMARC could benefit from the approach the Miami Valley Amateur Radio Club takes in using and policing their impressive repeater system.

At exactly 7:30 a net control stations signs on 146.76 (I understand they're changing to 146.64, but that's beside the point). He solicits check-in's and just logs calls as fast as he can. He announces that this is a regular meeting of the club, that each check-in will have a chance to be heard and after a brief "business" meeting there will be a technical talk by one of the members.

By 7:40 thirty amateurs had checked in, including W2NM. Net control then solicited comments from each check-in in the order they checked in. Comments ranged from complaints about rag-chewing (and a restatement of the club policy regarding same – they discourage rag chews on the repeater) to quality of signals and very brief descriptions of equipment that individual members wanted to get rid of. Such offers were followed by a brief pause, and in almost all cases arrangements were made for "land line" contacts to discuss details.

When it came my turn one of the members broke in and asked me to tell them about New York repeater operations. They were impressed and very interested. You should have heard the groans when I gave them the LIMARC frequencies. They were also surprised to learn that there was no useful 34/76 repeater in the New York area.

After a very brief business session, certain committees reporting (such as an apparently effective crystal acquisition committee) one of the members spoke on receiver trouble-shooting. He was most enlightening, and he let the repeater drop periodically for questions – which were frequent and very intelligent.



The technical talk was followed by a general roundtable and some pleasant yakking.

So an excellent meeting was held, information exchanged, club policy restated, equipment exchanged, etc., and nobody left the comfort of his home! (By the way it was snowing and very cold.)

You might consider a similar operation for LIMARC. It works!

Jim Fahnestock W1NM

WITH THE FCC

The Fiscal Year 1970 FCC Report includes a comment that 2491 violation notices were issued aginst hams, as compared to 2464 in 1969. One percent of the American ham population is not bad, but it should not be that high. Many notices were due to lower class licensees operating in band segments reserved for higher class licenses. The Citizens Radio Service had 1409 notices in 1970 as compared to 2400 in 1969. There seems to be little effort to catch illegal CBers or else it is very difficult to identify people who do not give any identification. It is unknown at this time what proportion of the ham violation notices led to further FCC action as compared to those of the Citizens Band.

To mark the 75th anniversary of the Marconi Kemp Tests of 1897, the Barry College of Further Education Radio Society is issuing an award, in the form of a certificate, to radio amateurs who provide proof of contact with Commemorative Stations, established in various parts of the world, and amateur radio stations in Italy and Britain.The award will be made available to amateurs and short wave listeners for a period of approximately 12 months, starting on May 13, 1972 with the establishment of the Bristol Channel Commemorative stations at Lavernock Point, Flatholm Island and Brean Down, and ending May 31, 1973. All questions and comments should be addressed to the Awards Committee, Barry College of Further Education Radio Society, College of Further Education, Colcot Road, Barry, Glamorgan, England.

* * *

The Lockheed Amateur Radio Club again sponsors the biggest annual ham convention in the Los Angeles area. The date this year is May 20 from 10 A.M. until 8 P.M. There will be an interesting program and prize drawings and a good time for all. The site will be at the Lockheed plant in Burbank, seven blocks east of the Hollywood-Burbank Airport.

* * *

The Baton Rouge ARC will hold its Eighth Annual Hamfest May 6 and 7 at Father Colbert's Camp, just east of Baton Rouge. Besides the Hospitality Room and evening awards banquet, there will be a Swap-Fest on Sunday, contests for high speed code, home brew building, and a demonstration of radio control airplane flying. On Sunday there will also be a giant picnic featuring Uton Diez, the world's "Champion Jambalaya Cooker."

* * *

The Rock River Radio Club will hold its annual hamfest on May 28 at the Lee County 4-H Center in Amboy IL. The indoor all-day event begins at 8 A.M. Free coffee and donuts will be served while you inspect the gear at the tables. Free camping area nearby. For further information, contact Carl Carlson, P.O. Box 99, Nachusa IL 61057.

The Wabash County Amateur Radio Club will hold its fourth annual hamfest at the Wabash County 4-H Fairgrounds, Wabash, Indiana, on Sunday, May 21, rain or shine. Admission is only $1. There will be no set-up charge for the flea market. Activities include technical talks, free Bingo for the XYL's, and door prizes. Free parking. Camping is available on the grounds Saturday night. For more information write Bob Mitting, 663 N. Spring St., Wabash, IN 46992.

* * *

The Maryland Mobileer Amateur Radio Club will sponsor a Hamfest on Sunday, May 21, at Anne Arundel Community College, starting at 10 A.M The college is 6 miles north of Annapolis, just east of Route 2. Talk-in on 7255 kHz, 146.94 and 146.16/76 MHz starting at 8 A.M. Plenty of parking; lots of goodies. For further information contact Donna Fournier, Secy. MMARC, R. 1, Box 154, Discus Mill Road, Severn MD 21144.

* * *

USAF MARS Region 1 Convention will be held at the Statler-Hilton Hotel, Boston, Mass. on 19, 20 and 21 May. Lectures, demonstrations, exhibits, forums, eyeball QSO's, social events and a banquet highlight the affair. All interested radio amateurs are encouraged to attend. Contact WA1PBJ, John Donovan, 19 Pratts Junction Road, Lancaster RFD, MA 01523 for tickets and information.

* * *

The P.H.D. Amateur Radio Association will sponsor the third annual Northwest Missouri Hamfest to be held at Claycomo, Missouri on Sunday, May 7, 1972, from 9:30 A.M. till 4:30 P.M. The location will be in the U.A.W. hall across from the Claycomo Ford Plant on U.S. Highway 69 Alternate. This event draws the most active amateur radio operators from the states of Kansas, Nebraska, Iowa and Missouri.

* * *

The Annual Humboldt Amateur Radio Club Hamfest will be held Sunday afternoon, May 21, at the Shady Acres City Park, Trenton, Tenn. There will be door prizes, flea market, ladies' activities, and a playground for the children. For further information contact W4IGW, Edgar Holmes, 501 N. 18th Ave., Humboldt, TN 38343.

* * *

Free code and theory classes for ham licenses are held every Wednesday night at 8 P.M. at Land of Electronics, 400 South Main St., Lombard IL. Call Phil, K9DTB, for info (312) 495-1234.

The 39th annual Western New York Hamfest and VHF conference will be held in Rochester, N.Y. the weekend of May 12–13.

Activities start Friday, May 12th at the Rowntowner Motor Inn, 800 Jefferson Road (14623), new Hamfest headquarters.

Registration for this fabulous day is only $3. Combined registration and banquet in advance is only $7. Advance sale closes May 6. There will be only a very limited number of banquet tickets available at the gate. Write: WNY Hamfest, Box 1388, Rochester, N.Y. 14603.

The New York Chapter of the National Awards Hunters Club offers several awards for working various proportions of New York State hams. For more information about these certificates, write to Joseph Tricarico, WA2MWO, 338 Madison Ave., West Hempstead NY 11552.

Worked New Brunswick Counties Award

This award requires QSL cards from twelve counties of New Brunswick, each showing county, date, band, frequency, mode, and operator's name. Send cards to H. W. Gammon, VE1PM, 357 St. Andrews St., Bathurst, N.B., Canada.

PENNSYLVANIA

The annual Presque Isle Amateur Radio Club banquet will be held May 20, 1972 at the Concord Inn at North East PA. Social hour will be from 6:30 to 8 P.M. Dinner will be served at 8 P.M. The price is $5.00 per person. For more info write PARC, P.O. Box 1021, Erie PA or call AC 814 866-0491.

On May 21st, the Breezeshooters Eighteenth Annual Hamfest will be held at White Swan Park near Pittsburgh. This is the largest ham gathering of its kind in the area. Contact K3FGQ for more info.

* * *

The Sharon ARA will be holding a ham auction on Saturday, May 20, at the QTH of WA1LXE. The auction will begin at 1 P.M. Directions available by writing to Dave Fisher WA1LXE, 30 Ames Court, Sharon, Mass.

* * *

The Yellow Thunder ARC will hold its annual hamfest on May 27 at the Dellview Hotel, Lake Welton WI. For further information, contact Al Gallagher WB9BPL, 401 Market St., Lodi WI 53555.

EDITORIAL BY WAYNE GREEN

SCANNING GREEN

While some of the chaps on slow scan television have built their own monitors and cameras, and some have gone the EKY Video Vision kit route, most of the ops have gone first class with the Robot monitor and camera systems.

Imagine the chagrin of the chap who has spent nearly a kilobuck and finds he is now able to see Wayne Green making faces.

The Robot monitor and camera arrived the other day and everything else ground to a halt. Within a couple of hours the mating plugs had been made up and we were on the air with slow scan television.

The connections are simple . . . the monitor plugs into the regular mike input of the rig and the mike then plugs into the monitor so you can talk normally or switch over to sending pictures. The audio for the monitor is picked up off the speaker of the receiver. The camera plugs into the monitor and you're ready to go.

The first day on television we made do with signs propped in front of the camera which were produced with a broad black felt pen. The very first QSO was with W6IFL and Pete helped us adjust the contrast and brightness controls on the camera. Next came KL7HEE, then HK5HK and HK5BFK, KH6DEH . . . etc. All of these were what is called "closed circuit" . . . the pictures came in just as if they were from our own camera.

The next day we broke from work for a few minutes to see what might be coming in from Europe . . . ho, ho . . . HA7LF . . . not closed circuit with all that afternoon QRM, but perfectly readable. Mel W8UUS, an old friend of ours of twenty years standing, swapped pictures . . . then W1PFA from over in the eastern sector of New Hampshire for state number three. Bill's demo of the Robot system at a recent K1MNS repeater group meeting was one of the last straws that pushed us over the hill into getting on slow scan. You can talk about it and read about it, but until you see it you can manage to ignore it.

When Bill discovered that we were on SSTV he sent over a menu board for us to use. This is a black board with white plastic letters that can be stuck on in moments. With this contraption we are able to put the call letters of the station we are contacting up on it and make an instant on the air QSL. We rigged up the board to say, "Hi 4X4VB QSL de W2NSD/1 New Ham Shire 20 MAR 72, WAYNE – 73." All we do is change the call and show a few frames of this to QSL each contact. It becomes a CQ call by setting up a CQ in place of the DX call and QSL.

Once you start seeing the pictures of the fellows you are contacting you realize there is a lot of truth in the proverb about the difference between a man and a boy being the cost of his toys. But what a toy! On the second day of viewing we swapped pictures with VK5MF and three I's . . . then came the DX contest and all bets were off for the weekend of intense QRM Oh well, we did pick up a long "needed" FM7 contact during the contest for an extra country . . . we're around 300 now somewhere on 20 phone.

Day by day the slow scan countries and states are building up . . . the main problem is an almost total lack of time to operate. We can get in a few short contacts on FM from the car while taking Sage to the day care center or while going downtown shopping, but we don't have the repeater connected to the 20m rig yet so we're stuck down on 2m via W1ALE in Concord to a cross band on 6m. There is precious little activity on 52.525 except when the band is open and we can work W4's by the gross via the repeater. Other than that the main attraction is K1IIG down in Hartford who has a 450 repeater with output on 52.525.

We're up to 20 countries on slow scan, despite the limited time . . . perhaps an hour every other day. The latest was 4X4VB, our first Asian QSO . . . leaving only Africa for WAC. Since ARRL seems to have refused to provide an SSTV endorsement for their WAS and WAC certificates, it seems likely that 73 will try to plug this hole in the dike. There are some active African SSTVers, so WAC should come shortly.

What can you say about the excitement of sitting there watching live pictures from a DX station? Or from a friend you haven't seen for a while. The pictures are remarkably good, considering the limitations of the medium. In order to get the bandwidth down to ham band proportions it is necessary to effect some small economies here and there. A regular television pictures requires about 4,000 kHz bandwidth. In order to shoehorn this big thing into the 20m phone band we have to prune it by sending somewhat fewer pictures a second and fewer lines per picture. Fast scan runs 60 pictures per second . . . so if we chop that down to one every 8 seconds we have about 1/500th as many pictures to send per second . . . a dandy saving. If we cut the number of lines from 440 down to 120 we have cut another 1/4 . . . a total of about 1/2000th as much information per second . . . or about 2 kHz bandwidth instead of 4 MHz.

With pictures taking 8 seconds you have to hold still when you are shooting it "live."

Many of the ops are using the Robot monitor for receiving and using tape recorded signals for sending pictures. Robot will make up tapes for you . . . and so will any owner of a camera, so it is no big problem. Buster W9WED takes his cassette recorder along mobile and makes two-way slow scan contacts all with his recorder, sending his pictures from one cassette and recording the incoming pictures on another cassette. He then plays the tape into his monitor when he gets home and there are the pictures. He has several countries and a bunch of states worked two way mobile slow scan already.

There are at least 45 countries on slow scan for W8YEK has worked that many. You'll find a list of these contacts in the slow scan column this month.

ADDITIONS TO 73 STAFF

Yvette Grimes (WA8ULU (we all ate Uncle Louie's Underwear) has joined the crew at 73 as Assistant Publisher, an omnibus category which entails producing the 73 books and hypoing subscriptions among a long list of lesser duties.

Yvette is getting out several interesting books, including one on How To Use FM, written by W2NSD/1, a book of digital control circuits for repeaters, a book on slow scan television, one on converting commercial FM equipment, a book on 432 MHz construction projects, a transistor project book, and many, many others. She has her hands full.

Lin Green, wife of the publisher, has taken on the thankless job of Advertising Manager. This job involves an almost unlimited amount of details, the missing of any of which will probably result in the total alienation of at least one advertiser. Keeping the ads for eighty or so advertisers in each

issue of 73 plus those in the Repeater Bulletin all in order is a tough job.

Ed Webb W4FQM has signed on as Technical Editor of 73. Ed brings considerable design experience in solid state and IC's. Ed has considerable experience in RTTY, FM, SSTV and several other areas of the hobby. Watch for a lot more IC project material in 73.

HAM CELEBRITIES

W2NSD/1

Some amateurs are so starved for a celebrity to hound off the air that they will even tackle W2NSD/1.

Seriously, would you like to hear King Hussein on the air more often? Would you like to hear Arthur Godfrey around the bands? How about Barry Goldwater? Andy Devine? These fellows . . . and more . . . will be active and on our bands if only you will let them.

Put the shoe on the other foot for a moment. How long would you stay active on the bands if every time you gave your call you were forced off the air with breakers? Would you continue to ham if you found an enormous pileup every time you stood by? Would you enjoy the hobby at all if there was virtually no way to complete a contact? And if you get mad and complain then you are a bad guy

The next time you hear someone well known on the air why not just enjoy listening to him . . . or her? Help them to enjoy amateur radio so they will be with us longer. Jordon is certainly not rare anymore, so why not let King Hussein make some contacts without immediately jamming him right off the air as soon as you hear him? You lose . . . he loses . . . we all lose. The other evening I heard JY1 make a contact with someone he knew . . . and as soon as it was over the screams of anguished amateurs demanding a contact were heard nonstop for about ten minutes. One W4 called over 200 times! And he already had worked JY1, I remember working him from there.

We will have friends if we deserve them. Please, the next time you hear this nonsense going on, take the time to go on frequency and explain to the mob that they are helping to make life miserable for someone who should be a friend of amateur radio.

IS 220 MHz REALLY LOST?

The EIA seems to have its propaganda mills cranking out garbage full blast, perhaps even straining the almost inexhaustable coffers of the assorted unscrupulous manufacturers who are dreaming of a $500 million a year market if they can just get that band away from the hams.

The EIA lobby in Washington is totally unopposed by any organized amateur radio effort to save the band since we have no Washington lobby of our own. The EIA seems to be encouraging the manufacturers with pie in the sky promises of great golden rewards . . . just imagine the profits if one out of every ten new cars sold (10 million cars) had a $200 CB transceiver! That's $200 million a year!!! Then one out of two of those would buy a base station too . . . and add in business use for doctors, plumbers, salesmen, farmers, etc., and you have $500 million a year . . . yum.

The EIA seems to have managed to get the Defense Department to okay the deal, leaving it squarely up to the FCC. The FCC could hardly be less enthusiastic – and no wonder – they are at wits end with the present citizens band and the prospect of unleashing a new screaming mess of CBers hobbying away with illegal calls, illegal power, illegal antennas, and illegal language gives them the whim-whams. Can the FCC withstand the one-way pressure?

Can anything be done to save this amateur band? Is it really worth any serious effort to save? After all, it is virtually unused today, so why make any big deal out of it?

It may come as a shock to low banders, but the most used amateur band today, by far, is the two meter band. Over one third of the active amateurs in the U.S. are on two meters! You can't say that about any other band. In many areas of the country the top half of two meters is virtually filled . . . and in the case of New York, overfilled. The congestion there is a harbinger of what is to come for the rest of the country in perhaps another year or so.

Where do we go next when two meters is full? We go to 220, that's where. What about 450? This band is a lot fuller right now than you think . . . what with television using the lower third of the band, weak signal ops using the center third and FM repeaters and control links using the top third. There is room for expansion on 450, but not a whole lot in urban centers. No, we need 220 . . . we need it now . . . and we will need it desperately in another couple of years unless FM growth suddenly stops . .. and there is no reason to expect anything but continued growth of FM since it is one of the biggest bunches of fun amateur radio has ever provided.

I am convinced that 220 MHz can be saved for amateurs . . . and saved in its entirety. I believe that we have the thinking part of the FCC on our side and that if we give them any reasonable excuse for saying no to the manufacturers that they will indeed say no.

Time is short .. . painfully short. If we dawdle for a few more months there will be no way to save the band. The way to save it is the obvious one . . . use it. Use it or lose it, a good slogan and an accurate one. So how can we use it . . . in a hurry?

The prospects of much more AM or sideband operation on 220 are not encouraging . . . but more FM would be simple and could be quickly organized. If every repeater group in the country made it a crash program to put on a 220 repeater . . . NOW . . . we could have somewhere between 500 and 1000 repeaters on 220 MHz by fall . . . and I think, if we could do that, we would have ourselves an amateur band and no great big CB mess.

This plan was unfolded before the representatives of about 50 northeastern repeaters at the Shrewsbury FM Symposium in February and every single two meter repeater group agreed to put on a 220 signal as quickly as possible. The first on were the WA1NXG repeaters in Connecticut, with both WA1KGQ in Vernon and WA1KHA in Torrington going on full 220 repeat in early March! Bruce and the group are to be congratulated!

The big holdup for large scale integration of 220 is obviously the lack of equipment. There is little available in quantity for the band. This is being corrected, thank heavens. Ed Clegg has announced that he will soon have a 220 transceiver available . . . plus a 220 repeater package. TPL, which sells through Henry Radio as Tempo, will be making deliveries of their long-awaited 220 transceiver ($179) and that should get things moving. This is an AM-FM rig, for both crystal and vfo use. TPL is also working on a 220 repeater package which is expected to be priced at about $300. Look for 220 gear from Avcom, Standard, SBE and others before long. By fall the rush to use 220 may be on in earnest . . . perhaps we can save this one. You may be sure that every piece of 220 gear that comes out will be reported in depth in 73.

Credit where it is due: the ARRL filed a comprehensive comment with the FCC supporting the amateur need for the 220 band and pointing out the reasons why CB use of the frequencies would be to the advantage of no one except a few manufacturers.

The future of 220 MHz is up to you. Members of repeater groups should raise cain until a 220 transmitter (at the least) is put on. Please be sure to let me know when you get on the air so your transmitter can be listed and the FCC can be advised of your use of the band.

What channels to use on this band? The northeastern repeater groups decided, after a lot of hassling, to run all

(continued on page 10)

W2NSD *continued from page 9*

repeater inputs starting at 221.98 and going down every 120 kHz for each succeeding channel. The outputs would be 3 MHz above that, starting down from 224.98 MHz. Narrow band, please. The coordinator for the northeastern part of the country for this band (and all the other FM bands) is Pierre Catala F2BO/W1, 180 Maple Street, Needham MA 02192. As soon as coordinators are available or known for other parts of the country I will pass along their addresses.

THE SON OF 160m

Amateurs of my vintage can remember with great warmth the old 160 meter band, back when it ran from 1800-2050 kHz for phone and was the very best band we had. It was great for local and relatively short distance contacts and it was nice and wide . . . for those days. The other two major phone bands were restricted to Class A amateurs and were each only 100 kHz wide, and were each just about permanently filled with a handful of smug kilowatt nets . . . it only took nine of them to fill up each band.

The FCC tells us that it should not be long before that dratted Loran is removed from 160 and the band can again be turned over to amateur use. It's about time . . . Loran has been bypassed technologically for quite some time and has just been hanging on and on and on.

Say . . . perhaps you'd better pass along a note to your favorite manufacturer and let him know that it might be prudent to add one more position on the band switch of future models . . . and calibration for 160m. This will be one hellova band when it gets going again. You wait and see.

ROLLING OFF A LOG

About 75% of the FCC complaints against amateur have to do with the keeping of logs. This has nothing to do with any directives from Washington, but seems more to represent initiative on the part of a few engineers in charge of FCC monitoring stations. One is inclined to wonder why these chaps are not spending their idle hours trying to stem the flow of obscenity and linears on 11 meters instead of harassing amateurs over a regulation that is of utterly no importance today. Other than the fact that logs have "always" been required, what possible reason is there for keeping them? Logging has been done away with for many services, yet just because it still stands on the books for amateurs some engineers are making life absolutely miserable for quite a number of amateurs.

SSTV SCENE

SSTV reminds one of the early days of SSB. Remember when there were only a few SSB'ers, and they gathered on specific frequencies? Remember when DX stations first started appearing on SSB; the "Quacking;" the "Different type" pileups? The resemblance between the start of SSB and the start of SSTV is phenomenal. If this is any indication of things to come, SSTV may grow to be as popular, or more popular than SSB. And why not? Commercial TV replaced radio to a large extent, did it not? Soon "just talking" to a guy will be a mode of the past. Each day more and more of us are getting to see, for the first time, the fellows we've been talking with in the past. And believe me, that's quite a surprise. As the XYL, WB4OEE, said the first time she saw W7ABW, "But that's not how he sounds like he would look." Indeed, very few people do sound like they look. It's just that you don't notice it if you meet them in person. Sound interesting? Right on! Maybe I've enticed you to at least investigate slow scan TV. Chances are you'll find it the most fascinating aspect of ham radio since the spark gap.

The 1972 slow scan contest activity appeared heavier than last year, and band conditions were very good. There should be some high scores this year. One couldn't help but notice the way EA8CI was picking off QSO's on 20 meters. And 15 meters was usually good for a few more countries. There was a definite trend this year to the use of white lettering on a black background for ID's that seemingly punched through QRM. And I never heard last year's winner, W9NTP, on at all. Don?.

Recently while working one of the SSTV gang, the question of power and final tube life came up. I was quite surprised to find the other station was running around 600 watts average output on SSTV, while I was running 50 watts output, average, on SSTV. Our pictures were closed circuit both ways. He was also having trouble with short final tube life under these circumstances. While I watched, he reduced output down to 50 watts. His signal dropped from around 20 over 9 to about S9. The pictures were still perfect copy.

This brings to focus an important point newcomers may not know. The use of reduced power is proper in slow scan TV. Since the 1200 Hertz carrier is constant, the duty cycle is 100%, the same as leaving a constant carrier on the air. Modern rigs can withstand this punishment only a few seconds; thus cutting back power output is the logical answer. Granted, 50 watts may be an extreme on low power and 600 watts may be an extreme on high power, but I think you get the point. The least power necessary to maintain a solid copy QSO is usually much less than you suspect. Most of the old time SSTV'ers who have a KW linear run 150 to 200 watts on SSTV, and have found these conditions a happy medium between tube life, signal strength, and QRMing others. A little experimentation on your part will show you your best power for your rig. And remember, reduce output power by decreasing mike gain and camera or tape recorder output, not by loading the amplifier lighter or (gad) by dropping the linear and putting a super heavy load on the poor exciter. Remember – let the rig and linear loaf along!

It's good to see exotic DX and celebrities on slow scan. 9K2AM, 9Q5BG and others keep the boys hopping on 20, and Barry Goldwater, K7UGA/WA7UGA had some good pictures for the slow scan net (14.230 MHz, 1800 GMT, Saturdays) last Saturday. He was 20 over 9 here in Birmingham, Alabama. Now if we can get the boys to move the camera off Barry and show us around that fabulous station of his!

I hope I'm not letting the cat out of the bag, but – the plumbicon tube can be used directly on slow scan – no expensive fast scan and sampling techniques involved. The tubes are difficult to find (TV station pullouts are the only way) but once you've secured one – WOW! More info on this will be available later.

Some of the gang are getting quite a few countries on slow scan now. Who's the W8 with 40 plus countries? W4MS and VE7JA are in the high thirties – no telling how many W9NTP has – I'm still plodding in the mid-thirties. How about you? Drop me a card and tell me your SSTV total, and maybe a good off-the-air photo you'd like to show in this column. Or, tell us about your special SSTV project you've been working on. It will be quicker to send mail to me directly, rather than through the

73 would appreciate getting a copy of any correspondence you may have received from an FCC engineer regarding logs. Perhaps, by making the names of these chaps public we can discourage them from pursuing this vendetta against hams.

Mind you, we don't in any way condone illegal amateur operation . . . over power, stuff like that . . . but we do want to try and protect individual amateurs against harassment, from any source.

. . .Wayne

73 office. My address is: *Dave Ingram K4TWJ, Eastwood Village #50N, Rt. 11, Box 499, Birmingham, Alabama 35210.*

Here is a list of some active DX stations using SSTV, thanks to W8YEK, who worked them. Look for them:

CT1PG	IS1GF	VE6RM
DJ0CN	KH6DEH	VK5MF
EA4DT	KL7DRZ	VP9GR
EA8CI	KP4GN	W4MS
EL2CB	KX6DR	XE3DX
F6AXT	LA3SG	XW8AX
FG7XT	LU7AAG	YN3RBD
G5ZT	OK1GW	ZL1AOY
GW3DZJ	ON4DN	ZS3B
HA7LF	OZ4IP	ZS6UR
HB9IT	PA0LAM	4M2BC
HK7X1	PY2EEG	4X4VB
HR3HH	PZ1DA	GY5PB
I1LCF	SM4AMM	9K2AM
	SV1AB	9Q5BG

Following is a suggested signal reporting system for use on SSTV:

R S-V

R = Voice readability 1 - 5

S = Signal strength 1 - 9

V = Video readability 1 - 5

V0 = Nothing decipherable

V1 = Occasional letters come through, difficult to copy

V2 = Call sign readable, pictures visible, if not identifiable

V3 = Good copy on some pictures, occasional complete pictures

V4 = Good copy most of the time, photos recognizable, some interference, multi-path fading etc.

V5 = Solid closed circuit pictures

That's it for now. See you on SSTV.

K4TWJ

Worked all Mass. Cities & Towns Contest, 0001 GMT June 11 to 0400 GMT June 15. This is a maximum of 100 hours. Exchange: Signal report, City (or Town), County, and State. Scoring: One point for each Massachusetts station worked regardless of band. Final score is the number of different Mass. stations times the number of different incorporated Mass. Cities & Towns worked. Operators may enter as single band or multi-band stations. A certificate will be issued to the winner in each State, Province, and Country in each class. In case of ties, the entry having worked the most Counties shall have the higher position. Entries must be received no later than July 31, 1972. Entries must show date and time of Mass. stations worked plus the "exchange" information. Submit entries to Warren Baker W1DFR, 66 Rexford St., Mattapan MA 02126.

6 METER

THE FIFTY MEGAHERTZ BAND

W4GDS, known to many for his daring exploits as ZF1RS during several previous VHF contests, is planning to go even further afield this year. Bob has already been issued the call VP5RS and if everything gels as expected he will be active from Cacios Island for several days around contest time. Cacios, in case you don't know, is one of a group of islands located approximately 500 miles southeast of Miami and 175 miles north of Port-Au-Prince. Tentative plans call for a beacon which would be operative even if the band isn't open. Details will be published as they become available. By the way, Bob, do you really think you can get United to stop there?

While on the subject of DXpeditions it might be well to mention that the people who undertake these trips for our pleasure do so at their own expense and often require (and always appreciate) an SASE. The same is true of Stateside operators who live in sparsely populated States. The burden of postage on hundreds of cards each year is too much to bear. You can make life easier for these people and insure receiving a QSL by doing this small courtesy.

The annual VHF Conference of the Central States VHF Society is scheduled for the weekend of August 18-19-20. Now is the time to start making plans to attend. The society net meets at 2130 CST on or about 3980 kHz on Sunday evenings. Give a listen - you will hear a great deal of interest to the VHF-UHF devotee.

The near complete silence has been broken! The evening of March 5th brought a rather extensive opening from 7 Land as far east as the third call area. Glen WA7FPO, could be heard working Missouri, Kansas, Oklahoma and Tennessee, among others. The 5's in Texas and Oklahoma also got their share working into Florida and most of the Midwest. A report was received to the effect that the border states had earlier in the day heard signals from Central and South America; however the report has not been confirmed as of this writing.

In building several dozen KW PEP linears of the type described in the July 1969 issue of 73, a number of changes were made which may be of interest to those planning a similar project. The chassis size was changed to 8 x 10 x 2½ in. in order to allow the same amplifier to fit either the Swan or Heath speaker cabinet. Components originally mounted on the side of the chassis were moved underneath maintaining the same relative position. Each screen is now fed through a separate No. 327 lamp and bypassed by a 13K, 10W resistor. The resistor biases the lamp on so that less screen current is required to blow the bulb. It may be necessary to adjust values in the screen supply to compensate for the additional current. With this modification it is no longer necessary to change one tube at a time in order to determine which of the parallel pair is defective. The amplifier will run quieter if you tack the chimneys to the sockets with 3 or 4 dots of silicon rubber bathtub caulk. It stops the inevitable chattering.

Microwaves

Go away, appliance operators! This column is written for those amateurs enterprising (and foolhardy) enough to populate the amateur bands 1 GHz (1000 MHz) and above. Believe me, there is darned little commercial amateur gear up here.

So, for those who have what it takes to venture into black magic land via this column, let's lay some ground rules for the care and reading of the new microwave bulletin board.

This column belongs to you, the experimenter and microwave communicator. Any topic you wish clarified, any product you want the world to know about, and especially any news you may have to share with your fellow microwavers – all it takes is a postcard. This column can't exist without inputs from *all* of you.

1 GHz (1000 MHz) will be considered the "normal" lower cutoff frequency of interest, but an occasional venture to 450 will be made.

Waveguide & Widgets (New Products)

Fairchild reportedly has a 25¢ computer diode oscillating in the Trapatt and Impatt modes. The diode is the FD-300, and several people report powers (pulsed Trapatt) of several *hundred* watts around 500 MHz. CW Impatt oscillations around 3 or 4 GHz (no power level given) with this device has also been noted. For more information, see February 1972 issue of IEEE – "Transactions on Microwave Theory and Techniques (MTT)."

Thinking about next Christmas for your least-liked friend? Give him some new 15 GHz (yes, that's right, 15,000 MHz) ARSENIC transistors. The arsenic doping allows emitter regions to have a 1 micron (1/1,000,000 meter) width. The arsenic also allows you to create a pretty spectacular whodunit. This is more completely described in *Microwave Journal* February 1972, or write to Fairchild Semiconductor, Palo Alto CA.

Above the noise

Pete W6DXJ, Carl WA6RGH and Jim WB6BHI, have claimed a new amateur S-band (2300 MHz) record. It seems Pete and Carl had the first amateur phased-array (one-way) contact; Carl and Jim had the first phased-array to phased-array (two-way) contact, all over a closed 100 meter course. More information on this is being prepared for publication.

Microwave mumbo-jumbo

You may have a question or two about frequency designations in the microwave region. This one is typical:

What is "S" band and why is it so named?

It started a long time ago when scientists were inventing radar. Radar, by the way, was classified "Top Secret" during WWII. Even the name radar was "TS." Naturally, the frequency used was secret also, and what is more secret than "X."

So they called the old radar band (10 GHz) X-band. After the war, when things loosened up a bit, they began experimenting (mostly amateur experimentation – at that time we had all bands 10 GHz and above) with other frequencies. The old radar terminology stuck, and they began naming other bands apparently at random.

Herewith a tabulation of the letter bands:

Letter	Frequency Band	Amateur Band
P	200–400 MHz	220–225
L	400–1500 MHz	420–450
		1215–1300
S	1.5–40 GHZ	2300–2450
	1500–4000	3500–3700
C	4.0–6.0 GHz	5.65–5.925
X	6–12 GHz	10.0–10.5
K	12–36 GHz	21–22
		All above 30
Q	36–46 GHz	All
V	46–56 GHz	All
W	56–100 GHz	All

Thus, to speak of amateur "S" band, either 2.3–2.45 GHz or 3.5–3.7 GHz is the band in question. To distinguish, the terms "High S" or "Low S" are used to determine a particular band.

Amateur High S = 3.5–3.7 GHz.

Amateur Low S = 2.3–2.45 GHz.

Jim Weir, WB6BHI

Military Affiliate Radio System

MARS is made up of licensed hams who are interested in military radio communications. Separate programs are operated by the three services, all using similar rules. Any licensed amateur, sixteen or older, who has a station capable of operating on the assigned MARS frequencies (usually just outside the regular ham bands) may apply to the service of his or her choice for MARS membership. To apply, simply write for a MARS application to one of the following:

ARMY: Room 1C475, The Pentagon, Washington DC 20315.

AIR FORCE: Bldg. H243, Tempo E, 4th & Adams Dr. NW, Washington DC 20333.

NAVY-MARINE CORPS: 5827 Columbia Pike, Bailey's Crossroads VA 22041.

"Okay," you say, "I know how to get into MARS, but why should I join and what do I do after I get in?" The answer is complex – first, you take your place with a growing number of active hams who are getting invaluable training in military communications – who serve as an immediately available auxiliary communications system for the Armed Forces in the event of an emergency – and who handle countless thousands of morale-building messages and phone patches for our servicemen overseas. As an active MARS member you will be eligible for certain surplus equipment – some so sophisticated as to be beyond the reach of the average ham, and you will be eligible for correspondence courses from the various Armed Forces Schools and Institutes – courses that will take you from the basics through space technology, and at no cost! This column is not to be construed as a sales pitch for MARS – just the facts. More on responsibilities and benefits in future MARS columns.

Welcome to new Chief MARS Army, Col.(Ret.) Robert B. Woodside A3ZLH, who is a long-time active MARS member and former Maryland State Director. Acting Chief Joseph Ziglinski A4DIN, will remain as Assistant. Congratulations to A3ECP, another long-time Maryland State MARS Director, who was awarded the Army's Oustanding Civilian Service Medal . . . First Army has a code proficiency program, 4001.5 kHz, on the second Sunday of each month at 6:30 PM EST.

The State of Virginia is covered completely with a 2 meter MARS network, and plans are underway to link the entire First Army Area from Maine to Virginia! Repeater inputs are on 148.01, out on 143.99 as in most Army installations. MARS members from other Army areas are welcome to use these facilities when in the First Army area, according to Command MARS Director Bob Sheridan, and the same policy has been placed in effect by Third Army MARS Director Hal Mulkey and Fifth Army MARS Director Roland Belk. Perhaps by the time you read this the Sixth Army will have joined in the "reciprocal trade treaty!" Meanwhile, if you are a MARS member traveling in a different Army area, don't hesitate to use the facilities – the worst thing that could happen is for someone to tell you you are not authorized for that area – something that happened to no less a personage than Acting Chief MARS Army A4DIN!

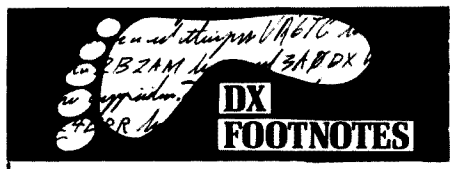
* * *

Director A3EGN reports the installation of Delaware's first Army MARS 2 meter repeater. A1W, Southern New England Army MARS Director announces their spring meeting will be held at Natick, Mass., on either the 13th, 20th or 27th of April – check

locally if you plan to attend. Their first repeater will be installed at Ridgefield soon. The first New Jersey Army MARS repeater is being installed, just in time for the spring membership meeting at Fort Dix, and the spring dinner-dance at Fort Monmouth (you thought MARS was all work, huh?). A2BVE reports that New York, New Jersey and Pennsylvania held a very successful combined emergency drill on 6 February.

* * *

Congratulations to Air Force MARS – they have *35 repeaters* working in their Northern Communications Area! This includes 6 in Pennsylvania, 5 in New York, others in DC, Virginia, Connecticut, Rhode Island, etc.



Armed Forces Day is Saturday, 20 May – the annual opportunity for hams to work crossband with MARS HQ stations WAR, AIR, NSS and NPG, using all modes. In addition there is a 25 wpm code proficiency test and a 60 wpm RTT test and all contacts are acknowledged by colorful one-time QSL cards. The activity starts at 10 AM EDT and runs until 1045 PM EDT. Frequencies are too umerous to mention here, but look for the HQ stations just outside either end of 80, 40, 20 and 15 – they will announce what frequencies they are monitoring.

The 15th Annual Third Army MARS Conference will be held at Fort McPherson, Georgia, near Atlanta, ith over 600 members and guests, on 14 and 15 April. In addition to the riter's wife AL4ECK, other important personages will include Maj. Gen. eorge Pickett, Jr., A4DIN Acting hief MARS Army and Roland Belk, Fifth Army MARS Director. You are nvited to visit with us and watch the op brass hobnobbing with the parking lot attendants, doctors, farmers, etc.

Other meetings: Texas Army MARS 13 and 14 May, El Tropicana Motor Hotel, San Antonio – New Mexico State MARS 20 and 21 May in l Paso, Texas (Bet there's a story here!) – Missouri Army MARS was eld 8 and 9 April – Louisiana 15 and 16 April – Wisconsin 22 and 23 April, ansas 29 and 30 April – Arkansas on 6 and 7 May. Consult your local irector for detailed information.

WAR is NCS for a new nationwide raining net on 6977.5 kHz, seven ays per week, 8:30 AM EST until 10 PM EST. All Army MARS members are invited to check into this net when possible.

Harry Simpson A4SCF
P.O.Box 27015
Memphis TN 38127

If you are planning to visit Mexico and wish to operate from there, write for a permit to operate. Send to: Liga Mexicana Radio Experimentandores, AC Malinos, 51307 & 8, Mexico 19, D.F., Mexico. Do not contact the Mexican government directly. (Thanks to BCARA)

RYUKYU ISLANDS

The Ryukyu Islands will revert to the control of the Government of Japan effective 1501 GMT, 14 May 72 (001 hours, 15 May 72, Okinawa/Japan time).

Effective with reversion of the Ryukyu Islands to the Government of Japan, the amateur radio call sign prefix KR6 will no longer be authorized for use by U.S. Forces personnel stationed in the Ryukyu Islands. The call sign prefix KA6 has been authorized for these personnel effective with reversion.

In addition, third party traffic, phone patch/message, will no longer be authorized to or from the Ryukyu Islands as they will be under the administration of the Government of Japan which prohibits this type of traffic.

* * *

All cards for WB4FWV, WA7MEA, DL4EQ, PA9FJ, HS2JR, HS2ACA & YBØAAW should go to DK1RR.

* * *

As of 1500 hours GMT, 14 May 1972, the KR6 prefix will terminate and will be replaced by KA6.

* * *

The Okinawa Amateur Radio Club (OARC) will change its title to Okinawa Radio Club (ORC). QSL cards may be sent via the KA6 QSL Bureau, Okinawa Radio Club, Ft. Buckner, APO 96331, San Francisco, California. QSLs sent to this address are limited to members of the radio club. Prior to sending a QSL card, you should determine by asking whether you should send direct or via the bureau. Request has been submitted to ARRL for the Ryukyu Islands to remain a separate country for DX purposes. We have also been informed there will be no third party traffic either to or from KA6.

* * *

Countries that share reciprocal operating agreements with the U.S.: Argentina, Australia, Austria, Barbados, Belgium, Bolivia, Brazil, Canada, Chile, Colombia, Costa Rica, Dominican Republic, Ecuador, El Salvador, Finland, France (and possessions) Fed. Rep. Germany, Guatemala, Buyana, Honduras, India, Indonesia, Ireland, Israel, Jamaica, Kuwait, Luxembourg, Monaco, Netherlands (and possessions), New Zealand, Nicaragua, Norway, Panama, Paraguay, Peru, Portugal, Sierra Leone, Sweden, Switzerland, Trinidad & Tobago, UK (and possessions), Uruguay, and Venezuela.

* * *

Third Party Message Agreements: Argentina, Barbados (U.S. stations operating /8P), Bolivia, Brazil, Canada, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, El Salvador, Greenland (XP calls only), Haiti, Honduras, Israel, Liberia, Mexico, Nicaragua, Panama, Paraguay, Peru, Uruguay, and Venezuela.

* * *

From MARCO Bulletin

In September of 1971, there was a change in Japanese law, permitting use of amateur stations by Americans; however, due to the complexity of the procedures, there have been almost no cases of this system being used. It is almost impossible for a foreigner to operate an amateur station in Japan. Thus the plan of letting foreigners use club stations was devised. If a foreigner is registered as a member of a club consisting mainly of Japanese, he can operate the amateur station. It's just that call signs cannot be issued to foreigners as individuals. A case in point: U.S. Ambassador to Japan, Armin H. "Hank" Meyer and Mr. Alfred C. Roussean, who was in Kyushu for a short stay, were aware of this. The call signs were W3ACE/JH1YDR and W1FJJ/JA6YAO respectively.

* * *

From MARCO Bulletin

SSTV DIRECTORY TO BE PUBLISHED

Robot Research Inc., is preparing a world-wide directory of active amateur radio slow scanners. A statement appears in their brochure calling for amateur radio operators who are active in the operation to file their names and call letters. In return they will send a free copy of the directory when the calls are in and compiled. Write to: *Robot Research, Inc., 7591 Convoy Ct., San Diego CA 92111.*

LETTERS

"You have made my day!"
George K3QHY

In the mid 1930's we, W9PRH, W9STT and W9UJC, lived within a block of each other in Bismarck, North Dakota. As time we on each moved away and we lost track of one another. W9PRH eventually ended up in California. W9STT also was in California (Los Angeles). W9UJC moved to Billings, Montana. W9PRH let his call and license expire, W9STT became W6WKY, W9UJC became W7FKW. W6WKY and W7FKW established written communications and kept in touch by Christmas cards and notes over the years. In January 1970 W6WKY and W7FKW got together on the air and made a sked for the next day. During the QSO that followed we got to reminiscing about old times and friends and our travels. We were talking about ex-W9PRH and wondered what had happend to him.

Unknown to us was the fact that ex-W9PRH had moved to San Pedro, California, and had purchased a used receiver, had it on and was listening on the same same band and frequency and heard us talking about him. He got our addresses from a Call Book and wrote to us. We were amazed and surprised to hear from him. What a coincidence that he should hear us! As a result ex-W9PRH got re-interested in ham radio, boned up and got his ticket: WA6AYA. The three of us have had skeds on Sunday for some time. W6WKY and WA6AYA had an eyeball during the summer of 1971 and in Feburary 1972 the three of us had an eyeball at the home of W6WKY at his Los Angeles QTH. What are the odds on something like this happening?

M. Hansen W6WKY
Los Angeles CA

About 3 to 1.

Please put me on the 73 subscription list. $6 is enclosed. Keep up the emphasis on FM. Also please put me on the Repeater Bulletin mailing list. (I use K1FFK). I hope to work you soon through FFK. I'd like to see an article also, on a moderately priced homebrew or otherwise synthesizer.

I'd like to see an FM contest — maybe number of stations worked with a repeater multiplier and a multiplier for handy talkies. Some way, though, the repeater should be kept open for non-contest use. I disagree about shifting the National XCVE frequency from 94/94. We have two repeaters here that have 94 outputs (K2AE and WB2NNZ) plus direct activity as well and because of the capture effect things seem to work out fine. In fact there is an advantage as direct people can talk to many mobiles who are one channelers either NNZ (34/94) or AE (46/94).

One more thing. I cast a yea vote for 10 meter repeater links. I'd also like to see a sideband link for 15. How about output on 21.445 to stay away from DXing and other non-repeater activities.

Jon Soffer WA2LXI
Albany NY

The consensus re FM contests is yeccch.

You talked about someone on two meter FM working DX through a link and I heard it today. Operating on 2 meter FM with 1 watt WB8AGZ/OE9 was working through OE9JKI/mobile OE9 to OE9AHI who was working on 25 meters to a W8 in Michigan. The copy was 100%, S9+ both ways. It was so good that I listened instead of getting the tape recorder on line to make a tape. The only thing that could have been better was for the WB8 to be on skis not in his warm-up boots.

Jim Kirkgasser WA2ELA
Dewitt NY

Looks like Austria's getting ahead of us.

ERRATA

In your Feb. 1972 73 Magazine I noticed an error in your "Tuning Mr. Morse's Key" article. The photos on pages 17 and 18 of holding the manual key and bug paddles have reversed captions. Check and you will see!

Peter E. Brown WA2PTW

That's not a bug paddle, it is a keyer paddle.

Morse Memory — Revisited

As a result of several letters and my own review of the Morse Memory (*73* December 1971), I have reviewed the article and the following corrections should be made:

1. In Fig. 1 an arrow is missing from the Memory Address to the Memory.

2. In Fig. 2, the Q output of A6 should be pin 6.

3. In Fig. 2 there should be switches shown from the four A1 gates.

4. In Fig. 2 the CS siwtches at the very top must have the unused terminal on each switch connected to +5.

5. There are a couple of discrepancies between Fig. 6 and Fig. 2. A7 (Fig.2) is not shown in Fig. 6. A7 (Fig. 6) is the 8 input NAND gate in Fig. 2. The 10K resistor in A5 (Fig. 6) should go to pin 9. Pin 13 of A3 (Fig. 6) should be DATA 1.

6. Now for Fig. 5: the −9 volt supply is obviously wrong. I built it with the bridge reversed and Q3 is PNP. Instead of the GE xstr for Q3 a 2N408 would be appropriate. Also T3 should be marked 12.6 volts.

I'm sorry for the inconvenience this caused the many people who wrote to me, and the many more who didn't. The Morse Memory does work. Good luck.

Hal, WA6ATT

How about more articles on 6 meter FM & SSB operation. 2m has been fully exploited. For heaven's sake, keep us posted on FCC rulings on FM repeater operation! Much needed around here!

Mike, K7LYK
Seattle WA

POPULATION GROWTH

The purpose of this letter is to set forth an idea for increasing the annual number of hams. It won't require any action by the FCC, but it will evidently require a change of spirit in many of us.

Actually it is quite simple. If, since the day you became a ham, you have not yet been directly responsible for at least one new face in our hobby, then promise yourself, make a resolution, that you are going to get at least one interested person into the hobby this year (perhaps sort of as passing along the help you got when you were starting). Give that person help with the understanding that he (or she) will do the same tning in a few years.

So far, it is evident that this has not been done. While there were something like 17,000 new amateurs last year, this figure would have been about 50% larger if just ONE-TENTH of us in the U.S. had made the above resolution. Perhaps the lack of people who like to train new hams is due to the fact that many of us haven't tried it yet, don't think we're qualified, or don't think we have the time. Well, if you haven't tried it, why not try? If you don't think you are qualified, how did you pass the exam? If you

can't spare about 45 minutes per week for a few weeks, are you dead or something? Actually, all I'm trying to say is that helping someone else into a hobby that you know is really great is one of the most rewarding things you can do in ham radio.

In case anyone wonders what I've done recently, I've graduated a total of 90 new hams from 3 classes in 3 years. Age here is 18.

Just try it once this year, and see what a great feeling you get when that guy shows you the QSL from his first QSO.

John Kittler WA9ZXU
Rock Island ILL

That's great, John. We should do everything we can to promote interest in ham radio. I recently received a letter from a young person who wanted to become a ham and asked the assistance of an old timer. The OT said he didn't have time. With an attitude like that, it's easy to see why so many kids get into CB. Ham radio has so much more to offer. Boy Scouts need merit badge advisors. High schools sometimes have hobby shows. Maybe your club can operate Field Day on the town common while a few members explain what is happening and why. There are hundreds of ways to involve others in ham radio. We owe it to each other to do it. Now.

KIND WORDS

I'm a Junior at ISU and have been away from 73 and ham radio for several years.

I'm happy to be getting back to both now. I just thought I'd take time out from studying for final exams to tell you how pleased I am with 73.

Mark Lund WAØRAO
Ames, Iowa

Hey, if you run into WØLR, who hates 73, say HI!

I just received my first issue of 73 which I can call my own and almost immediately got a friend of mine to subscribe. It sells itself and is much better for someone with QueSTions than another mag put out by someone else.

Seriously, I think that the idea for 2 meter repeaters is great, but the manager of this station, whose call letters I would rather not have printed, says that a tech signal may not be repeated into the upper class segments of the band. Would you please clarify this for me?

Name withheld by request

Once everyone has this clarified, repeater growth will sky-rocket. The apartment dweller without the ability to set up outdoor antennas will soon be able to be repeated around the world while he sits at home with a little ground plane hanging from the ceiling. Techs can be repeated into other bands under the correct licensing procedures.

I don't like the new look of 2 meters (FM, crystals, "CB like" etc.) and it was my only VHF operation about 3–4 years ago. Thank God 80m CW hasn't changed. I subscribe to no ham mags now. 73 will be the only one.

W. R. Meador WA8TRB
Niles Michigan

The fastest growing aspect of ham radio obviously has a bit to recommend it. Try it – you'll like it.

I like to read 73 and wouldn't miss an issue. I have been here in Texas two weeks and a few of us are putting up a repeater in nearby Wichita Falls with 34–94 facilities. It will be open, carrier operated, and a Touchtone autopatch planned. There is no call letter for it yet.

Don Fraser WA9WVS

34–94 repeater #543 being planned.

I have been slogging through mud and snow down to the local electronics store every month to buy your stupid rag since issue No. 1. The proprietor laughs in my face each time I pick my copy of 73 off the shelf and occasionally sics his dog on me as I leave. NO MORE! I refuse to be made a fool of. 'Tis time my mailman, a professional slogger, earned his keep by delivering that stupid, atrocious, unauthorized, irreverent, unofficial nothing you so flippantly call a magazine. Enclosed you will find my subscription. Hah! Now who's stupid?

Walter A. Miller WA9BUN
Park Ridge, Illinois

It's abooouuutt time.

I recently completed three terms as SCM of Georgia and am a loyal league member for nearly forty years. I have not always agreed with your views regarding the league, nor have I always been in sympathy with the attitude of the league. In fact my split feelings prompted me not to offer for reelection and to discontinue league activity although I remain a member in order to have the right to voice my opinions.

Howard L. Schonher W4RZL
Columbus, Georgia

The only one who agrees with Wayne all the time is Wayne, and even then . . .

Thanks for an excellent issue on CW. You can t be as one-sided as anti-FM'ers think you are, if CW made the front page. In all sincerity, 73 is still as different from the other three to keep me a subscriber.

W6GMD/7

CW and FM were just subterfuges. SSTV is the only way to go.

Got a huge charge out of our brief SSTV QSO this AM! It will certainly do no harm to SSTV to have one our our most outspoken editors "seen" regularly! (Won't hurt 73 a bit, either!)

You may not recall, but almost two years ago you forwarded my request for help to Ted Cohen W4VMF. Ted was extremely helpful, guiding me along the not-too-well-trodden trail to successful SSTV operation. I had built the K7YZZ scanner and had the very great pleasure of a 2-way QSO with Lou himself during my first attempts at pic transmission. Also worked Ted finally.

I am slowly converting to solid state and adding a Plumbicon camera. It is only through this activity that I have had the opportunity to learn anything about digital and linear IC's.

Please keep a ready supply of such info on hand for future articles, even if they may be somewhat redundant in basic topic.

Availability of IC's at low cost, including op-amps, balanced modulators, PLL's etc., are all resulting in a re-emergence of the true "ham," the experimenter, innovator, developer and TEACHER!

Lee Clough W5GQV
Waco TX

STUDY GUIDES

Allow me to congratulate you on helping me pass my Extra theory exam. The series you ran in 73 was most helpful and rather painless. I have had success with others using your General series, also.

Jefferson Junior High of Champaign has a ham radio club which was formed last spring. I am their sponsor and teach Math and Science there for seventh grade.

William B. Vokac K9WQY
Mansfield, IL

It's sure good the way you fellows get info in one place and in a form even one as nontechnical as I can "dig." Good? It's great!

Sara A. Thompson
Houston, TX

KUDOS & QUERY

This is just a short note to make several points. The first is I enjoyed the February 1972 issue more than any since I started reading 73 two years ago. The QRP projects are probably the best way to go for those who wish to put some zip back in their operating time and get into the home-brew game.

The second point is that I believe the manner in which you have organized your journal, monthly topics, is very useful. The ideas in one article reinforce those in another, which at the same time serves to generate new ideas and approaches to a subject.

And now my third point. Do you think you could prevail on the Tempo people to come out with some information on the new 2m AM/FM transceiver you discussed in an editorial in the fall and that was advertised in the November 1971 issue? I would like to know when they intend to market it

(continued on page 16)

LETTERS CONT.

and would like more information on it. We still have a fair amount of AM 2m activity (in addition to the repeaters in the areas) in central Connecticut. Therefore it would be an ideal rig for this neck of the woods.

David J. Norden W1GDM

As information on the AM/FM rig becomes available we will pass it along n 73. It might be helpful to understand that the Tempo FM transceivers are made in Japan and marketed through Henry Radio. This apparently results in a slightly lower dealer markup for other dealers, with the result that the Tempo gear is not urged on customers as much as higher profit items, to the detriment of this fine equipment. The Tempo amplifiers are made in California using U.S. components by TPL Company and are marketed for hams through Henry Radio. This also holds for the recently announced 220 MHz AM/FM transceiver which should be coming off the assembly line in the latter part of April. The 146 MHz version of this unit probably will see the light of day along toward the fall or end of the year. If it looks as if it will break sooner you will find out about it first in 73. In the meanwhile there is the Comcraft 2m AM/FM rig, which is very nice and fun to use . . . if rather expensive.

RTTY ART

Regarding the article in the January issue, RTTY ART MADE EASY, in the contents you state "A new art form is born." At first I objected because RTTY "art" has been around for years. Then I had second thoughts regarding WA6PIR. I've copied him on amateur RTTY and, friend, your statement is entirely correct, a new art form *has* been born!! Don has taken it out of kindergarten and put it up with *real* art. I have some of Don's art that you didn't print and that also is really fantastic. Thanks for running the article.

"Bud" Resch WØFTD

W. M. Richarz WA4VAF

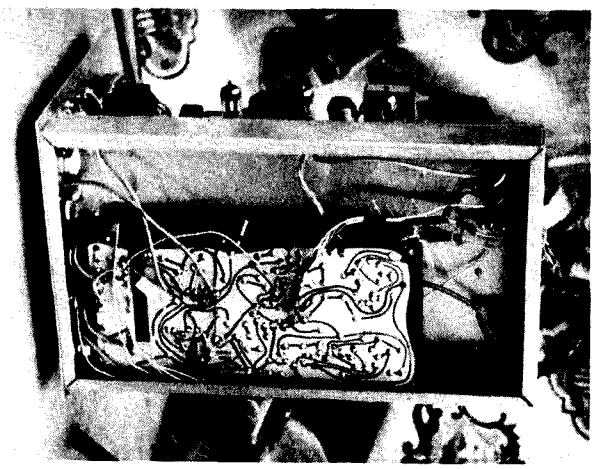
Charlotte NC 28215

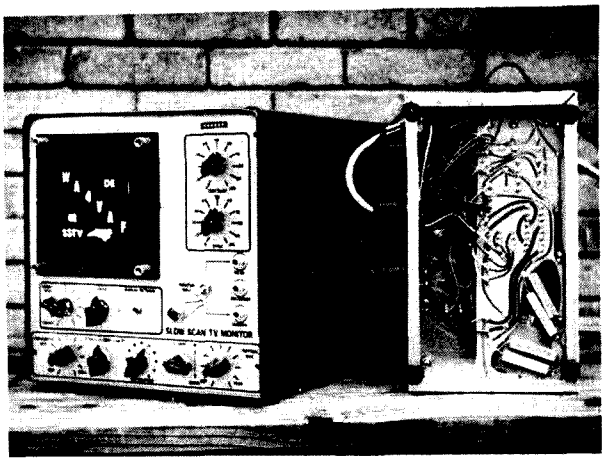
SSTV MONITOR THE EASY WAY

One afternoon about six months ago while tuning across the lower end of the 20 meter phone band, I came across some very odd sounding signals. They were musical like notes similar to Teletype, but it wasn't Teletype. I listened further and found it to be two stations transmitting slow scan television. One station commented he could see the cracks in the other fellow's teeth. That did it. I was hooked – I had to have one of those things. Well, right there was the catch. There wasn't a thing that was commercially built that I could just go out and buy. A few weeks later I did see an ad of Robot's in one of the ham magazines. The price came to about what I would expect to pay for a nice transceiver. No way to get that by the XYL.



The completed monitor in store-bought cabinet. Outboard power supply on top. Panel was given a professional look by silk screening. Also note high-voltage wire enclosed in vinyl sheath for neatness.

In the meantime I had written to W4UMF[1] and sent along a self-addressed, stamped envelope, for a bibliography he had compiled. After going over the bibliography and locating most of the articles, and also discussing SSTV with the fellows on the SSTV net, I decided to build the Macdonald Monitor[2]. Along the way I noticed an ad in *73*. EKY Video Vision[3] had a kit of parts to build the monitor for a modest cost. One could also buy the two PC boards for a nominal fee and supply the parts himself. After looking over the parts list in the 1964 *QST* article and pricing them, I chose to order the complete kit. My junkbox was at



an all time low at this time, since I had made a move a couple of years before. New parts are high these days, but a fellow who has the time and patience plus a few good friends with well stocked junkboxes, can build this monitor for less than the cost of a lifetime subscription to *73*.

EKY was a little slow in getting the kit to me but that gave me some time to scrounge a 5ADP7 from a local surplus store, complete with mu metal shield for $5. I also ordered a cabinet and chassis from one of the popular mail order houses. I chose a cabinet that resembled EKY's in the ad. I wanted this project to have a good appearance since naturally I would have to be looking at it when it was in operation, and I dislike looking at a sleazy panel with controls and switches haphazardly protruding from it. I also wanted a professional lookng panel and wrote EKY for a drilling template, explaining what I wanted to do. EKY replied by asking me to mail my panel to them and they would silk screen it for me at no charge. This they did and in a few weeks I had a very good looking panel that only required drilling.

The kit arrived, and on inspection everything looked okay. There were a few parts that were substituted and these were noted in the boxes in which they were packed. Some of the small transformers would not exactly fit over the holes that were predrilled in the boards for them. It was no problem to drill additional holes to accommodate the new parts; after all a fellow with

Underside view of the monitor. Plenty of space for deflection board and power supply would fit if you really squeeze it together.

The completed monitor. Underside view of power supply shows EKY circuit board that makes for simple construction.

an Advanced ticket who plans to operate SSTV should be able to improvise some. Instructions do come with the kit and they are also supplied if you order the boards only. Don't expect the instructions to match the big time kit-makers; no "red wire soldered to lug B, etc." The boards are silk screened on the component side with the part numbers indicated. The boards make the job of assembling the monitor a real snap compared to what one would have to do with point-to-point wiring from the magazine article. Mounting of the shield, CRT and controls is left to the individual's preference. There are no instructions covering this since different chassis and cabinets may be used. There is mention of insulating the focus and brightness controls from the chassis or panel, since these controls have high voltage on them.

The picture on EKY's flyer shows the signal board mounted upright on the chassis next to the CRT. I chose to follow this layout as closely as possible since I had the same cabinet and chassis. The picture on the flyer does not show how the deflection board is mounted, but it is submounted under the chassis on standoffs. A large rectangular hole is cut in the top of the chassis to allow the tubes to protrude through.

About this time I decided to build the power supply outboard since it would be crowding things on the chassis, although it is possible to combine the two. Building the supply outboard is a must if the mu metal shield is not used. This works fine anyway

since you can also use the supply to power a flying spot scanner. I was looking ahead to this. I ordered the power supply PC board and components from EKY also as I could not locate too many of the parts. (They are not that hard to find if you are in no great hurry.) The PC board is a real life saver here also, and I would recommend obtaining it even if you do scrounge the other parts. Everything goes on the board easily and it makes the supply neat and compact. The supply itself is all solid state including a dc filament supply for all the tubes and a separate dc filament supply for the CRT.

I put the kit together over a period of several weeks, so all loose wires were labeled with masking tape as to where they should tie in or connect. No problems were encountered along the way. I used a nine pin socket and plug to connect the power supply to the monitor and a separate four pin socket and plug for the two high voltage leads. High voltage wire was used in these two leads and was run through a length of vinyl sheath for neatness.

Time for the smoke test. Apparently everything was wired correctly as nothing smoked or got hot. The instructions also include tuneup and operating procedure. Two TV horizontal width coils are tuned to 1200 Hertz and 2300 Hertz. The instructions call for an initial setting of the slugs and after tuning them with an audio signal generator they proved to be nearly correct. I suspect you could get away without tuning them with the signal generator as these two

The completed monitor with outboard power supply. Note the sub-mounted deflection board to the left and behind the panel. The cabinet which houses the monitor also has a neat carrying strap.

adjustments are not too critical. The trace on the CRT should appear in the lower right hand corner – mine was in the upper left. The instructions point out a possibility of this happening and the solution is to reverse the deflection plate leads. Having done this, the trace was where it should be. In getting ahead of the instructions I tried to center the trace on the face of the CRT. This was the wrong thing to do, as I found out after reading further along. An SSTV signal must be present to drive the sweeps and under no signal conditions the spot is kept off the face of the tube. This way you don't burn a hole in the phosphor of the tube when no signal is being received or have the tube covered with out-of-sync information during a weak signal period.

The only problem encountered was with the vertical sync adjustment. When a vertical sync pulse was heard the beam would not start a new raster. It took some fine adjusting but there was one best point where the pulse started the raster. Once this control is adjusted it need not be touched again. In fact, it is mounted on the deflection board and inside the cabinet, as is the horizontal sync control. The horizontal control setting is not at all critical.

I must admit I had quite a time adjusting all the controls on the front panel. A good tape of SSTV signals is a must and will make the job much easier. Trying to make the adjustments from signals off the air can be quite frustrating. A darkened room or shield around the CRT face makes for easier viewing. It took almost a whole day of playing with the different controls to become quite familiar with them. This is not to say it is hard to tune the monitor for SSTV, because it isn't. You do have to have a working knowledge of what each control will do and some experimenting and just getting the feel of the controls. Once the monitor is set up you need only touch the contrast and brightness controls, as you would a conventional TV set. Occasionally you may need to reset the sync control on the front panel to allow for variations in a transmitted signal.

So now you have a monitor and no flying spot scanner or camera to transmit. What can you do till then? A few sketches with

ERRATUM

On page 22 in the April 1972 issue of 73, a curious and inexplicable error was allowed to occur. Two lines of type were neatly lopped off the bottoms of the two columns on that page, apparently by the mechanical process of reproducing the photograph, thus rendering the text incomprehensible. To date, exactly one of you out there has noticed this egregious error. . .for his benefit we herewith print in full the two paragraphs affected:

In order to assure sufficient flow some small holes should be left in the lower chassis. Leave the holes open in the corners of the chassis as *manufactured, but close up the hole in the* octal socket and at the filament transformer with putty or plastic tape.

Parts placement is not critical. Keep components in the lower compartment away from the grid coil which is supported by the tube socket on one end and the grid tuning capacitor on the other. The grid *choke is made in the same manner as the* plate choke, but with only 30 turns.

There. That's better, isn't it? The missing lines are, of course, those in italics above.

Monitor in operating position. A hood was added to the monitor for easier viewing and with it full room lighting may be left on.

CQ de your call, test patterns and also good quality photos of the shack sent to an active slow scanner with a small roll of recording tape usually brings back all one needs to transmit SSTV from your tape recorder through the mike jack of your SSB transmitter.

The next project here will be an FSS. Here again there are many ways to go, but after looking over the bibliography I think I will try the one from *73* July 1967[4], or possibly EKY's FSS kit. Why not, since the monitor turned out so well.

The first step is definitely the monitor though. I have received many SSTV pictures from hams in the states and also some DX stations and with S9 signals the monitor really does an excellent job. At times when signals are down in the noise, a picture containing contrasting call letters can be seen and read when you cannot hear the station's call on SSB. There are probably quicker and easier ways to get on SSTV, and probably even better circuits with IC's, but for the fellow who wants to get a monitor going with a minimum of fuss and know-how, for the money, the EKY board and/or kit seems to be the ideal way to go.

A 40W 6-METER FM/CW MOBILE TRANSMITTER

This report describes a three-transistor transmitter capable of providing 40W continuous power output at 50 MHz in operation from a 12.5V supply.

The transmitter described in this article is designed for CW or FM operation; it is not suitable for AM operation at a 40W carrier level since this would require peak power voltage capabilities exceeding the rating of the 2N5849 final stage transistor.

A signal source providing 20 mW at 50 MHz is required for the transmitter. Provisions for keying or frequency modulation are not described, but such features can easily be added to fulfill the requirements for a specific application.

A schematic of the transmitter is shown in Fig. 1, and the performance data appears in Table I.

The first step in designing this power amplifier is determining the required number of stages and the necessary gain per stage. A block diagram as shown in Fig. 2 is helpful in this estimate. The desired output power is 40W into 50Ω. According to the data sheet, the 2N5849 transistor can provide 40W from an input power of 6W. If a 1W allowance is made for circuit losses, the required drive for the final stage becomes 7W. The 2N5847 is rated at a power output of 7W for an input of 0.5W,

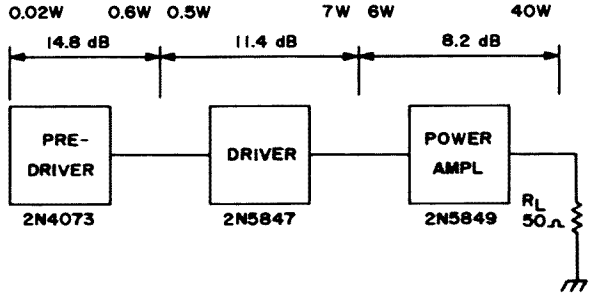

Fig. 2. Transmitter block diagram.

and the 2N4073 has sufficient gain to provide about 0.6W from 20 mW. This completes the block diagram and the basic specifications for the individual stages.

Circuit Description

The basic requirement of high power with good efficiency suggests a class C amplifier design, and the common-emitter

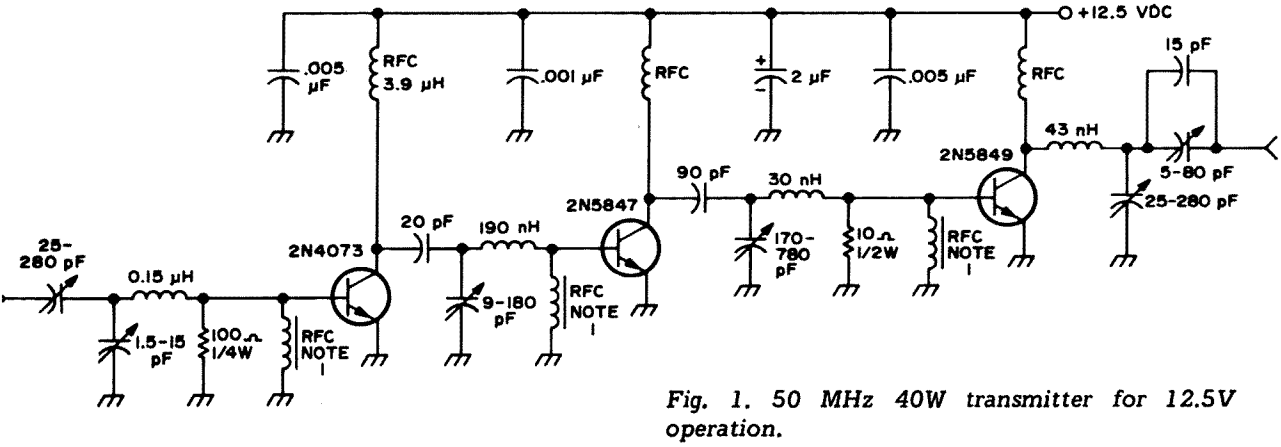

Fig. 1. 50 MHz 40W transmitter for 12.5V operation.

Table I. Transmitter Performance Data

Power Output	40W
Power Input	20 mW
Supply Voltage	12.5V dc
Total Current Drain	5.4A
Overall Efficiency	59.2%
Second Harmonic Output	25 dB down
Third Harmonic Output	45 dB down
Final Stage Current	4.7A
Driver Stage Current	0.65A
Predriver Stage Current	50 mA

configuration is selected for high power gain.

Final Stage Design. At the operating conditions applicable to the present design problem, the large-signal impedance data for the 2N5849 transistor have the values shown in Table II.

Table II. Parallel Equivalent Large-Signal Parameters — 2N5849

V_{CC} = 12.5V; f = 50 MHz; P_{out} = 40W		
R_{in}	0.8	Ohms
C_{in}	500	pF
Cout	625	pF
C_{out}		

The resistive portion of the collector load impedance, R_L, may be calculated (assuming a peak-to-peak collector-voltage swing of 2 V_{CC}) by using the expression:

$$R_L = \frac{V_{CC}^2}{2P_O}$$

where P_O = rf power output and V_{CC} = dc collector supply voltage.

For the 2N5849 the collector load is:

$$R_L = \frac{(12.5)^2}{2 \times 40} = 1.95\Omega$$

As the load impedance is small compared to the 50Ω termination impedance, the

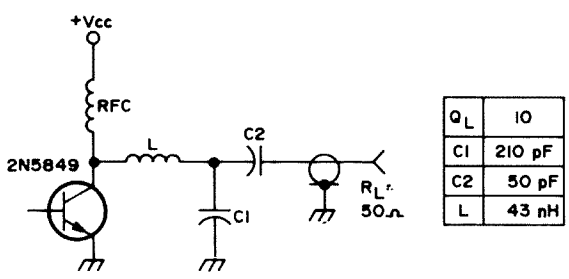

Fig. 3. Output network

network configuration shown in Fig. 3 is well suited for the final stage. The values of the network components may be found directly from the tables in Ref. 1. Several combinations are possible for the network components, depending on the value for Q_L, the loaded or operating Q. A loaded Q of 10 provides convenient component values, good harmonic attenuation and smooth tuning.

The driver/final interstage network must match the input impedance of the 2N5849 to the required collector load impedance of the 2N5847, which at the required drive power level of 7W is 11.2Ω in parallel with 160 pF. Reference 2 outlines a method for obtaining large-signal transistor impedance data.

Again a tee configuration is selected, and the circuit parameters are shown in Fig. 4. Proper biasing of the final stage is obtained by connecting an rf choke from base to ground. The selection of this choke is somewhat empirical, but as a rule its

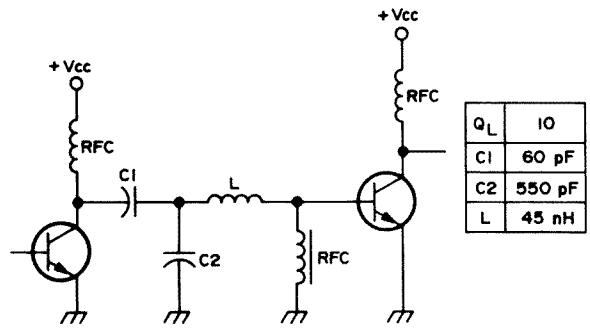

Fig. 4. Driver/final interstage component values.

inductance should be kept as low as possible, and it should be a low-Q type to avoid possible resonance with the base–emitter junction capacitance. Ferrite-bead chokes are well suited for this application.

It is also important that the resistance of the collector choke be as low as possible. In rf power stages, collector currents are often several amperes in magnitude: therefore, resistances as little as 0.1Ω can cause significant power loss.

Driver Stage Design. The tuned network must match the output impedance of the predriver stage to the input impedance of the 2N5847 driver stage. A tee network is

chosen, and the computed circuit parameters appear from Fig. 5. Biasing of the driver stage is accomplished in a similar fashion as for the final stage.

Predriver Stage Design. All that is required to complete the design of this stage is determining an input network providing an impedance match between the input impedance of the 2N4073 transistor and the 50 + j0Ω generator impedance.

Following the procedure outlined in Rf. 1, the network shown in Fig. 6 may be calculated. Component values are shown in the figure.

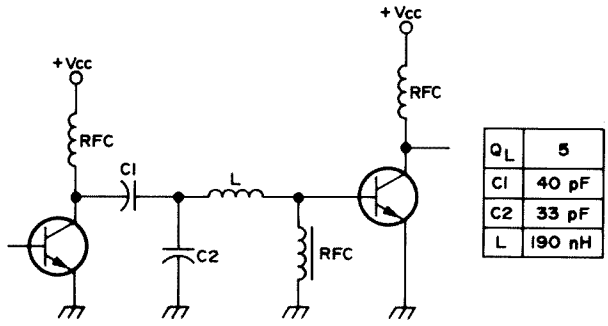

Fig. 5. Predriver/driver interstage component values.

Thermal Considerations

From the performance data listed in Table I, the power dissipated in each stage, P_D, may be calculated using the expression:

$$P_D = P_{in(RF)} + P_{in(DC)} - P_{out(RF)} \quad (2)$$

Solving Eq. (2) for each stage in the transmitter yields:

Predriver: 45 mW
Driver: 1.625W
Final: 24.75W

A heatsink for the output transistor may be evaluated from the expression:

$$\theta_{SA} = \frac{T_J - T_A}{P_D} \quad \theta_{JS} \quad (3)$$

where T_J = maximum junction temperature,

T_A = ambient temperature, and

θ_{JS} = junction-to-heatsink thermal resistance.

Furthermore:

$$\theta_{JS} = \theta_{JC} + \theta_{CS} \quad (4)$$

where θ_{JC} = junction-to-case thermal resistance

θ_{CS} = case-to-heatsink thermal resistance.

For the 2N5849 transistor, the following thermal data apply:

$T_J = 200°C$

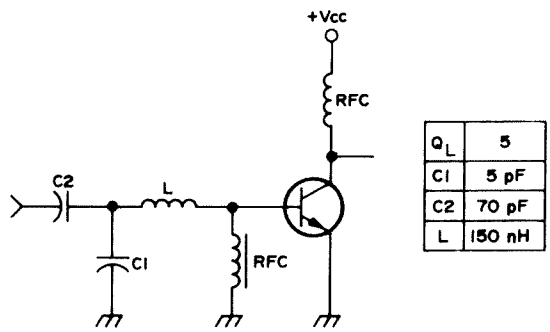
$\theta_{JC} = 1.75°C/W$

$\theta_{CS} = 0.25°C/W$ (Using a thermal compound and mounting nut torqued at 8 in.-lb)

Substituting the 2N5849 data in Eq. (3) for a worst-case ambient temperature of 60°C yields:

$$\theta_{SA} = \frac{200\text{-}60}{24.75} - (1.75 + 0.25) = 3.65°C/W$$

If operation at an ambient temperature higher than +60°C is desired, the device dissipation-derating information on the transistor data sheet and Eq. (3) and (4) may be used to complete the heatsink design for all three stages.



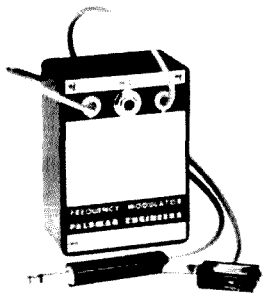


Fig. 6. Input network.

Construction

In the construction of the transmitter, the usual precautions normally taken in rf work must be observed. The selection of ground points is particularly important. The chassis current path between the base-choke grounding points and the emitter grounding points must be kept very short to reduce inductance. Variable capacitors are used in the tuned circuits to facilitate adjustment of network loading and tuning. A fixed capacitor is used in parallel with the output-stage series capacitor to provide protection against complete decoupling of the load.

FM YOUR GONSET COMMUNICATOR

- New! Plug-in modulator puts the Communicator transmitter on FM.
- No modification or rewiring on your Communicator. Just plug into mike jack and crystal socket.
- Compact self-contained modulator measures 4" x 3" x 1½".
- Works with Communicator I, II, III, IV and GC-105.
- FM at a tenth the cost of a new rig.
- Frequency adjust for netting built in.
- Built-in tone burst available. Keyed by push-to-talk switch.
- $34.50 postpaid U.S.A. Built-in tone burst $10.00. Specify Communicator model and tone-burst frequency. California residents add 5% sales tax. (HC-6/U crystal and 9 volt transistor battery not supplied.)
- Send for free descriptive brochure.

PALOMAR ENGINEERS

BOX 455, ESCONDIDO, CA 92025

All base chokes in this construction are low-Q types from the VK-200 series manufactured by the Ferroxcube Corporation of America. The 100Ω resistor in parallel with the predriver base choke and the 10Ω resistor in parallel with the final-stage base choke were incorporated to insure circuit stability for a wide range of drive levels.

It appears from the complete schematic of Fig. 1 that the fixed capacitors in the two interstage coupling networks are different from the calculated values. This is due to the fact that the type of capacitors used, phenolic-encapsulated silver micas, were found to differ from their nominal values at 50 MHz. The correct values of 40 pF and 60 pF were determined by measuring a number of capacitors.

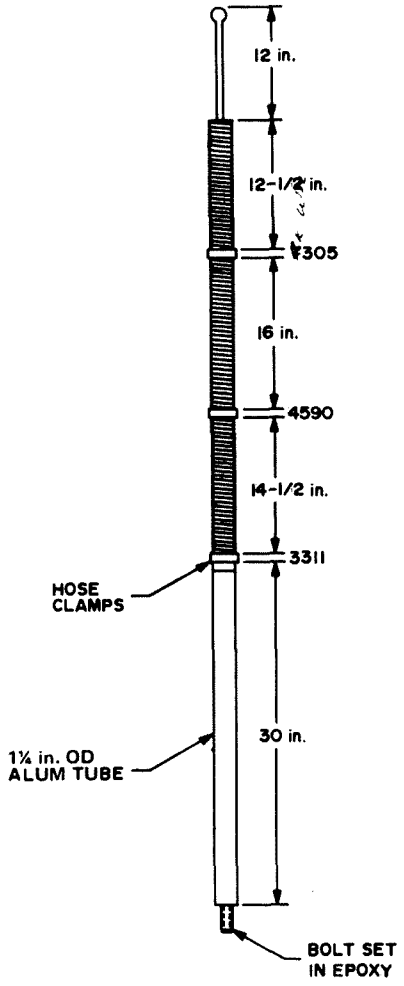
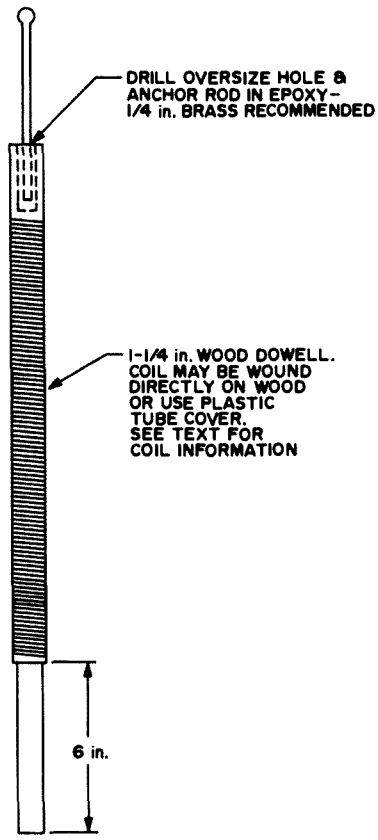
QUICK BAND-CHANGE MOBILE ANTENNA

All antenna systems represent a compromise. One of the greatest is that of squeezing a 3 MHz quarter-wave onto the back of an automobile.



A look at the price tag affixed to commercial antennas should provide you (as it did me) with a strong incentive for "brewing your own."



And price, while a major factor, may not be the only consideration. For example, I needed a positive, quick-change antenna, to hit Air Force MARS frequencies. Namely, 7305, 4590, and 3311 kHz.

The antenna shown in the picture is the result of four brewing ventures. Prototype

Antenna installed on 67 Chev. Used with Motorola SB3 Rig.
The coil is wound in two sections. Would be equally successful if wound in one section. Past models have been made in one section. Shorting bars in place for 40 meters. Two sections used here because of available coil forms.

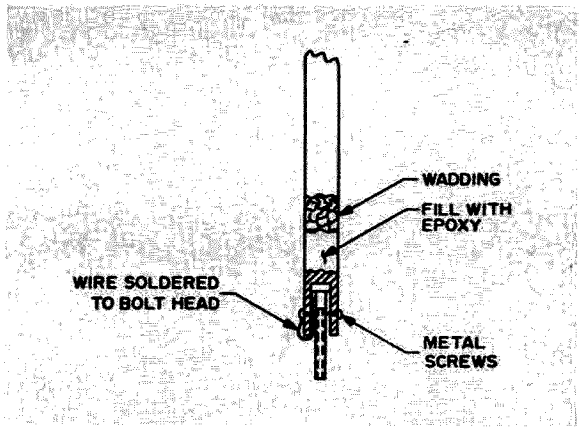
l was temporary, being wound on a bamboo fishing pole. Taps were brought out, with many trials and more errors; however, this temporary antenna worked so well it literally stayed on the car until the base "rotted" off. Had I coated the fishing pole with epoxy, I would probably still be using it. This antenna was wound with plastic-coated 20-gage stranded wire.

At the demise of the bamboo pole, I decided to be smart and refer to the handbook. I read and studied, and ended up with a very nice looking "outer-space" antenna, with a big-wire coil in the center. The transmitter loaded. The receiver worked swell. Only one small problem: Nobody could hear me.

Maybe it wasn't quite that bad. But the signal was down many dB. The center-loaded antenna did not deliver the signal that the top-loaded fishing pole punched out.

So I set to work to rebuild a better looking and more rugged "fishing pole."

The antenna now in use has two coils, each 2 ft long. The only reason for using two coils is that by loosening a clamp, the top section of the antenna may be easily removed. Also, it requires a long coil to hit 3311 kHz, and the necessary forms may be available in shorter length. Whether the coils are wound in one or two sections makes no difference in the operation or tuning of the antenna.



Also, a shorter coil length may be used if only higher frequencies are to be covered. For 40–10m, a coil about 14 in. long is required. (Increase base length to 60 in.) For 75–10m, approximately 3 ft is needed.

Actual construction and tuning of the antenna is easy. No special tools or equipment is necessary.

The base section of the antenna is a piece of aluminum tubing 30 in. long. The bolt, with threads to match a heavy duty spring mount, is securely anchored in the base with epoxy. Three sheet-metal screws,

Fig. 1.

with the tips filed so that each barely touches the bolt, are useful in two ways. Helping to center the bolt, and keeping the epoxy plug from turning in the tubing after hardening, braid is soldered to the bolt and brought out through a small hole in the tubing. The braid is later clamped to the antenna with a hose clamp which reinforces the base and holds the 47 dial light indicator socket. Wadding keeps the epoxy where needed. Be careful. The bolt must be straight when the epoxy is poured.

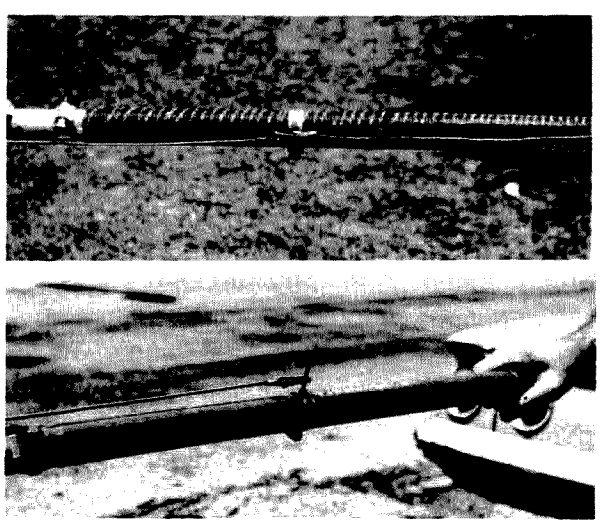
One satisfactory way I have found for winding the coil is directly over a wood dowel. If you have access to a lathe the dowel should be grooved to space the wire about one diameter. Or you may wind a string or another wire between turns, which may be later removed. (The coil should never be closewound, unless plastic insulated wire is used. The plastic provides the spacing.)

At least 6 in. of the wood dowel should be sanded, whittled, or turned down to fit snugly into the aluminum tubing base. Slot the top of the tube 1 in. A hose clamp will hold the coil in place and provide a terminal for the wire.

The tip section of the antenna may be any conductor. However, since this tip will receive some hard bumps, I recommend a section of ¼ in. brass rod. Solder a wire to the rod. A 5/8 in. hole is drilled in the end of the wood dowel coil form. Wire and rod are anchored in the dowel with epoxy.

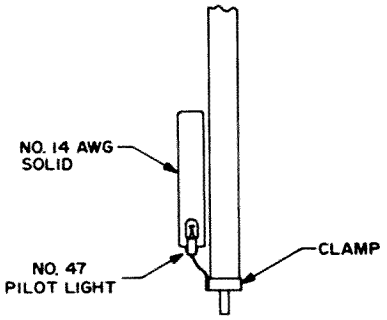
After the coil is wound and tip fitted, cover it with a good coat of resin to securely fasten the wire in place.

Another method of winding the coil is to use a piece of 1¼ in. plastic pipe or other coil form and slip this over the wood dowel, which may be an old broomhandle with a layer of tape applied. Fasten the ends of the plastic to the dowel with screws. Dowel should be long enough to extend 6 in. down into base. Tip is attached as previously outlined.



Or the plastic tube may be "splinted" to the base and temporarily "outside taped." Then the coil form and 6 in. of the base are filled with epoxy. The tip is placed in position and the whole thing hardens. This method is especially useful for the short coils, 40m and up.

A 36 in. plastic tubing form may be bought at a sporting goods store for about a dime. Just ask for the plastic covers designed to keep golf club handles from being scratched in the bag.



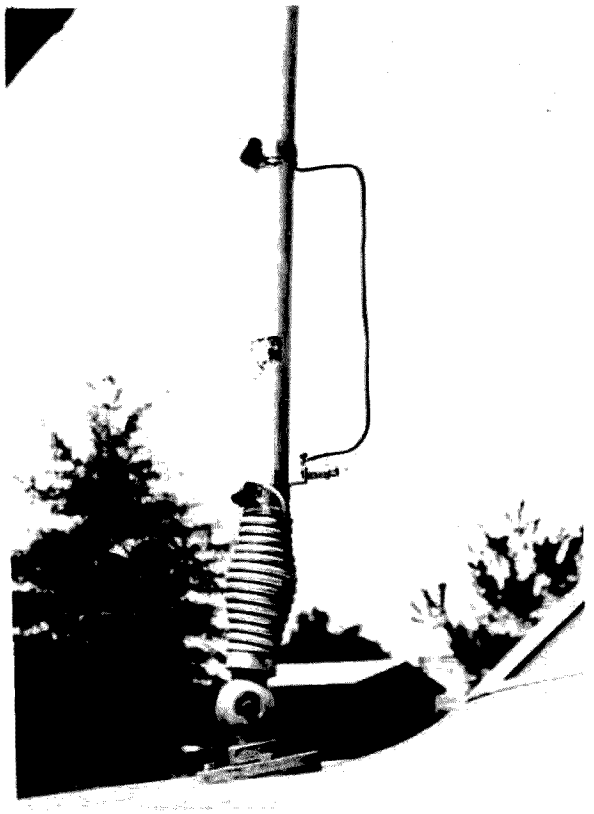
I have used coils constructed all of these ways. Using the wood is easier and works equally well. In any case the wire must be cemented in place.

After the coil is dry and both ends of the coil attached electrically to the base and tip, you are ready to start the tuneup.

For each frequency to be covered you will need a slider. Each slider is made of one hose clamp and one 6-32 brass bolt and nut. File the bolt head slightly flat.

Closeup of slider tap and shorting bar connections.

Indicator.



Drill a hole through the hose clamp. Insert the bolt from inside the clamp, securing with the nut. The bolt head will make contact with the wire coil.

By using the approximate measurements shown, estimate about where the tap should be for the frequency you wish to hit. With a coarse file cut through the resin and any insulation on the wire for 4 in. Your coil at this point will resemble a 100W slider resistor.

Now install the antenna on the car and place the receiver in operation. Work on the highest frequency first. For example I tuned 7305 kHz first. Then 4590, and finally 3311 kHz.

Attach a wire to the top of the base section long enough to reach the top contact area of the coil. Run the wire back and forth over the contact area. You will hear the receiver background noise peak sharply. If it fails to peak, but gets louder in one direction you may have to file some more. At the point where the receiver peaks, the antenna will take a load, but will probably require a bit closer adjustment.

Next install your output indicator, a 47 light bulb. I leave this indicator in place at all times. It provides positive "on the air" indication, not to mention what happens at night when a car pulls up behind and sees the sideband modulation waving in the air. The indicator is a loop of wire about 16 in. long, with one side of the loop taped to the antenna at the base and the 47 bulb in series with the outside of the loop. If it is desired to leave it permanently in the circuit it may be tapped across about 8 in. of the base using the antenna itself as one side of the bulb loop.

The 47 dial light output indicator. This light bulb shows at all times positive indication of on-the-air and is all you need to tune and load the transmitter. The loop in this instance is completed by the antenna itself. Can also be used as a complete loop taped to the antenna.

Using the bulb as an indicator, finish tuning until the desired loading is obtained.

Repeat the tuning procedure for each lower frequency desired. Then permanent shorting bars should be made. Brass welding rod and alligator clips are ideal.

Changing frequency is simply a matter of removing, or using the proper shorting bars. If several frequencies close together are required, several taps can be brought out every turn or every two turns, and a braid with attached alligator clip may be used to short out the unused portion.

This antenna has delivered plus performance. And when it comes to changing bands, it can be done in less than 30 seconds without hurrying, and this includes getting out of the car and back in. Every time the antenna will be in perfect resonance.

I scrounged everything. But if you have to lay out the cash, $5 should suffice.

Interested?

A Hi-Fi IC For Amateur Modulators And Receiver Audio

This is an introduction to the Amperex TAA300 Integrated Circuit af amplifier, a winner! When I say another winner I mean of course that it is Amperex who has the winner, because this little gem comes ready made for you in one of those little ten pin cans less than 3/8 in. OD. I should say nearly all as there is a collection of *external* accessories, some of which are much bigger than the IC itself. You can obtain these items in a much reduced size to match the IC, for a price, but we are concerned here with the Amperex TAA-300 IC af amplifier using readily available and amateur-priced parts.

Features of this device include high sensitivity, low cross-over distortion, low harmonic distortion, and high efficiency. And, I might add, a great sound!

See Fig. 1, internal diagram, and Fig. 2, the total circuit. This is one of those jobs using 11 transistors and four diodes when you might expect at the most, five active devices. However, any questions in my

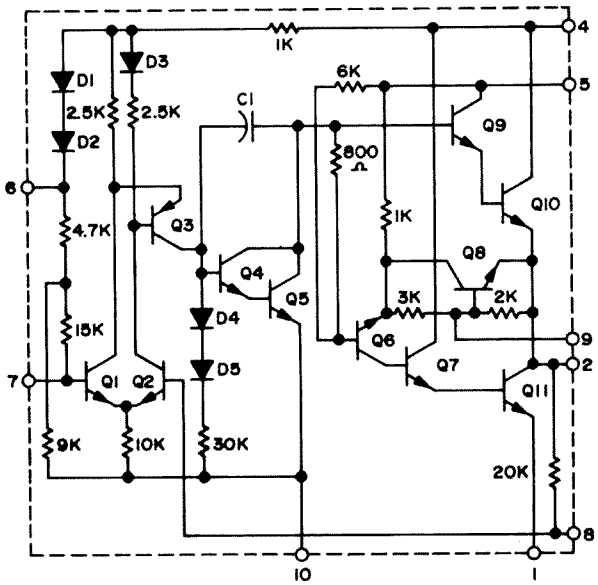

Fig. 1. Internal schematic of the TAA-300 Amperex audio amplifier IC.

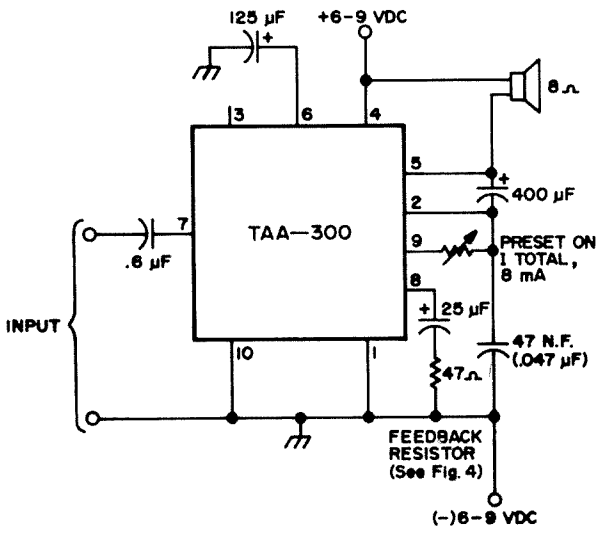

Fig. 2. External schematic of a complete audio amplifier using the TAA-300 IC.

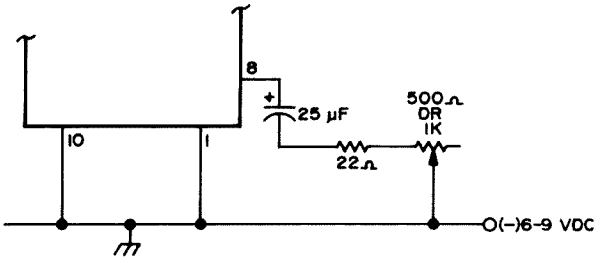
mind were immediately dispelled as I listened to it with my favorite mike and hi-fi padded earphones. It actually sounded better and clearer than any af amplifier I have heard in a long time, with plenty of lows and highs evident, and lots of power and gain too. Every one of those eleven transistors inside that tiny package are certainly doing their stuff in the proper fashion.

Special measures have been used to prevent cross-over distortion with a supply voltage ranging from 4.5 to 10V, dc. There is a "bias set" resistor running between pins 2 and 9 which serves to set the current to a rated 8 mA total on no signal (see details in the external schematics, Fig. 2). When this resistor is varied and the total current drops much below 8 mils you can hear the cross-over distortion begin on low volume signals such as whispering in the mike. When set at 8 mils, even the lowest volume signals are clear and free from distortion. The large amount of negative feedback also helps reduce distortion to a minimum. At a power output of 1W, which is the TAA300's rating with heatsink, into



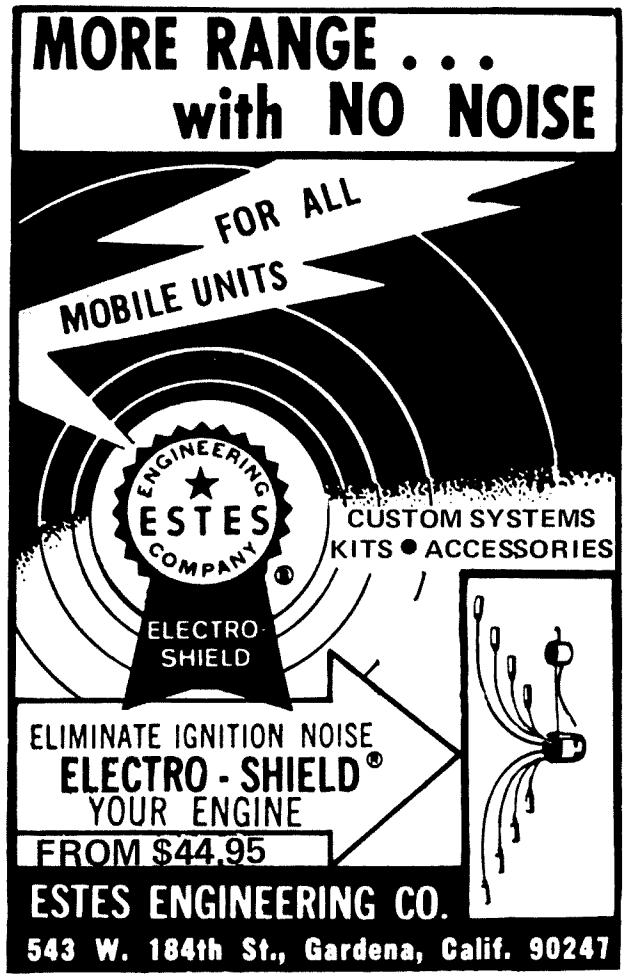


Fig. 3. Variable feedback control.

an 8Ω load, it still sounds great. The bandwidth at the 3 dB points goes from 30 Hz to 25 kHz, so, even though this sounds fine on a receiver, be sure and *reduce* that bandwidth when using it as a modulator.

At a power output of 1W the total current on the battery goes up to 180 mils, just like one of those regular old tube modulators you used to use. Of course the voltage is only ten so we're not talking about 180W, just 1.8W, which is still fine for portable all-solid-state rigs. The rated efficiency is 60%, which in my opinion is excellent for a good quality audio amplifier.

The input impedance is close to 10K and with my favorite mike, the Astatic

150, full output is obtained with the mike over a foot away. The reasons why the 150 is my favorite are: the price at $3.82, and the output of minus 44 dB which is the highest I know of. With no signal into the TAA-300 the noise can be heard in the earphones, but it is unlikely you would ever use that much gain. For all ordinary usage the amplifier is perfectly quiet.

The Variable Feedback Control

This feature certainly deserves a section of its own. Figure 3 shows the details. There is a 20K resistor carrying negative feedback from the midpoint of the output transistors Q20 and Q11, back to the base of Q2. This feedback line is bypassed to ground through a 25 mF capacitor. However, there is a resistor in series with this capacitor which in the external circuit diagram is specified as 47Ω. The amplifier works fine with that value, but wait until you try it with a variable 500Ω pot in its place! With the resistor value at zero, there is *no* feedback and the gain is terrific. With

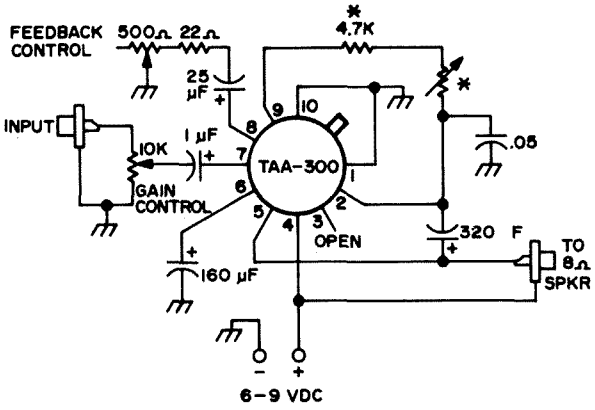

Fig. 4. Breadboard test setup for determining best values. Slightly different values are used here from Fig. 2. Read the application notes carefully for a list of the precautions to be observed while experimenting with this IC. Pin ten is also the case and can thus be grounded with a heat sink. A gain control is now always needed and may be replaced by a feedback control in some applications.

the pot wide open there is a lot of negative feedback and the gain is way down, but so is the distortion. Using the system as a gain control you are operating at all times with the least distortion and noise, and the feedback is at a maximum, which is good.

There may be a reason for not using this type of gain control, but since it sounds great I'm going to keep it in, particularly in modulator use.

Be *sure* and read the application notes if you are going to build. To prevent high-frequency instability, the following precautions must be taken: Keep the lead inductance from the positive supply voltage to pin 4 to a minimum. To counteract the high internal resistance of batteries, especially toward end of life, a 200 mF capacitor should be connected between 4 and ground. A capacitor of at least .05 should be connected between pin 2 and ground to prevent instability of the lower Darlington output transistor.

Avoid coupling between output and input leads, especially those carrying signals from a high-impedance source. This coupling can be reduced by using short leads, shielded input cable, or by limiting the upper frequency to 15 kHz by means of a 560 pF capacitor between pin 7 and ground.

The input lead and components will pick up lots of hum as a result of that excellent low frequency response if you do not take care with shielding. If you don't want all those lows, use a much smaller input capacity, especially for voice communication.

Layout

The layout I used for test purposes is shown in Fig. 4, although I imagine this can be packaged much smaller. The bulky items are the electrolytics, but once again Lafayette can help you reduce this size somewhat. I'll give just one example to illustrate. The 30 mF at 15V is only 5/16 by 7/8 in. long and costs only 23¢, if you buy 5 of them. Be sure and observe the polarity!

I used a 10K pot at the input, but with that fancy variable feedback bit you may not need it.

Be sure and follow the application notes, particularly the one about the lower Darlington output transistor. An input and output jack, a red and black battery lead, and you're on the air.

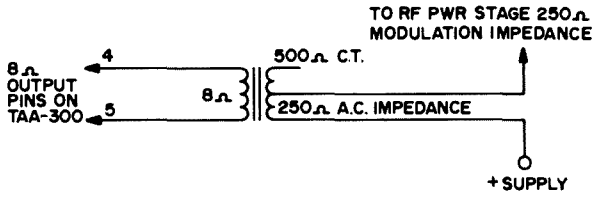

Fig. 5. Matching the output of the TAA-300 as a low power modulator using a small output transformer connected backwards.

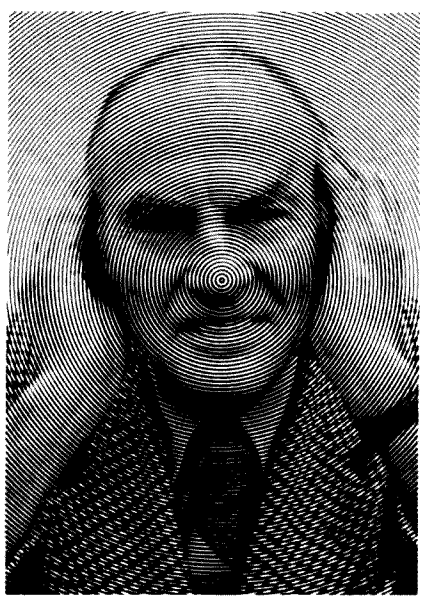
From the way this little diamond sounds you'll be meeting it again and again in modulators and receivers. I suspect it will be very useful along with a "turned-around" output transformer, with the 8Ω side connected to the TAA-300 output and the other side, whose impedance should match the modulating impedance of your rf output power stage, in the 50 to 500Ω range. It should be connected with the secondary carrying the modulated dc to the rf stage, as shown in Fig. 5.

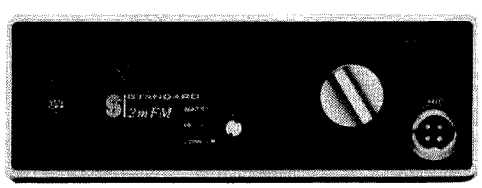
For receiver work just use an 8Ω speaker, period.

. . . K1CLL

Why won't Don Wallace listen to anyone else?



W6AM doesn't have to, since he began using our professional quality VHF-FM 2 meter transceiver with exclusive *Astropoint*. The precise and powerful Astropoint system actually blocks out all interference. So when one of the nation's number one hams is having a 2-way conversation he won't have unwanted interference.



Astropoint is featured on all standard transceivers including the rugged, 12 channel SR-C826M.

It's not only a compact mobile but even fully portable with the addition of a battery pack.

And there's a lot more that appeals to Don about the SR-C826M than just Astropoint. All silicon semiconductors with solid state circuitry. Ten watts of R.F. output power combined with low power consumption. MOSFET R.F. Amplifiers and mixers. And the list of features goes on.

Which is why Don Wallace hasn't been listening to anyone else lately. Not that he's choosy about who he listens to. Just whose equipment he listens on.

73 TESTS and USES

The Larsen 5/8 Wave Antenna

After a few months of FM'ing, talking with FM'ers, and seeing two meter mobiles by the gross, the eye gets used to seeing a disproportionate number of the Larsen antennas on cars. They stand out immediately to the eye of the FM amateur for the simple reason that they are probably the most inconspicuous two meter antenna there is.

Larsen came into the ham market via the two-way commercial field, as did repeater two meter operation. Naturally these old time two-way men brought along the antennas that they had found to work the best and give the least trouble . . . Larsen.

That little antenna coil on the bottom of the antenna will handle 100 watts, which today is about the practical limit for FM operation. The coil is needed to tune the antenna since it is not resonant at the 5/8 wavelength mode and a good deal of high efficiency inductance is needed to get the swr down to where the transistor rigs won't balk. The Larsen irons out the problem to an insignificant 1.2:1 swr or better.

Larsen goes that extra mile in efficiency by silver plating their whip. We all know that silver is a better conductor of radio waves than copper or chrome (remember those silver plated coils in the better rigs?), so silver is an obvious plus for a mobile whip. And remember that the silver stays a good conductor even when it is oxidized.

The 5/8-wave length is excellent for two meters since it is long enough to provide a lower angle of radiation (more on the horizon) and thus an effective doubling of both transmitted and received power (+3dB) without being so long that it is a hazard or looks too much like a Charlie Brown whip.

Not wanting to make any holes in the Rover 2000TC, the Larsen NLA-150 antenna with NLA-TMB (trunk mount bracket) was used, plus a coax feedline and hardware mounting kit NLA-1K (installation kit). The price of the works came to $24.50 + 3.50 + 4.50 = $32.50. That's a pretty good deal for a complete trunk-mount antenna, with feedline and connector, all of commercial quality and built to last longer than the car.

For details on all of the Larsen antennas and various types of mounts you can get specifications from *Larsen Electronics, 11611 N.E. 50th Avenue, Vancouver WA 98665.* You might mention 73 when you write to them and address your letter to *Jim Larsen W7DZL.*

HOW TO GET THE STUFF INTO THE HOUSE

Unless your QTH operates on the kind of budget that permits sable coat Christmas presents for the XYL, in-ground swimming pools for the kids, your own ski chalet at Aspen and casual weekend jetting to Acapulco or Majorca, chances are you are up against a problem that has faced nearly every ham since Marconi: *How do you get the stuff into the house unseen . . . or, alternatively, how do you avoid telling her how much it cost?*

Over a period of some years of supporting several hobbies and during which acquisitions of new and used cameras, lenses, fly rods, table saws, shotguns, sports cars, etc., to say nothing of radio gear, had to be explained, rationalized, lobbied or even concealed, this practitioner has assembled a variety of ploys, some from personal experience and others from fellow-hobbyists, whose contributions I acknowledge with thanks and whose identities I had best keep to myself.

In the hope that some fellow-sufferer may find herein the solution to his particular problem, I have decided to compile and publish the best of these stratagems in what might be called, *"Hamsmanship, or How to Build Your Amateur Radio Station Without Actually Shedding Blood."*

Old masters at the game – AM types and single-letter prefix gaffers – may find some of these tactics old hat. But they will realize that a whole new generation of amateurs has come along and, further, the problem of getting the stuff into the house without touching off domestic warfare has escalated astronomically in these days of nearly 100% store-bought stations. Even the newest Novice, judging from the magazine photos, starts his career with an array of commercial gear that looks like the control panel of an Apollo moonship.

These new hams need our help. Let us share with them our secrets and our methods. The future – possibly even the survival – of amateur radio may well be involved.

One word of caution before we begin the lesson: Do not, repeat, *do not* leave this copy of 73 lying about the house for *her* to read. Commit these pages to memory and then rip them out and either burn them or put them in an envelope and mail to Box 88, Moscow. That way they'll never be heard from again.

Now, then:

1. This one calls for the breezy, off-hand treatment. You bring in the new scope, linear, keyer or whatever it is and before she can start with, "How much did *that* cost?", you cry happily, "Boy, you couldn't beat this for $15" (or whatever figure the traffic will bear). Remember, you didn't *say* you paid only $15 for it – just that you couldn't beat it for $15 – and that's the gospel truth.

2. The David Harum or old-mule-trader ploy. You come gaily into the house with your latest treasure, a smug grin on your face, and emit something like, "Wow! Look what I traded old Haywire Magee out of for my old rotator." Never mind mentioning that you also forked over $250 in addition to that old rotator to make the "trade."

3. A variation of No. 2: Your line is, 'Can you imagine the dope letting this go for only $35?" You sure can't, OM. His rock-bottom price was $150 and that's what you coughed up. But you didn't *say* you paid $35.

4. Another variation: You take the old rig to your friendly local ham dealer who sells used gear on consignment for a commission. A few weeks later you report happily, "Some guy bought my old rig and I got enough for it to get this new one." Yeah, enough maybe for the down payment – but who needs to know you still owe the friendly local etc. $398.80?

5. Become a home-brewer. Spend long hours in the basement workshop. Cut lots of scrap metal loudly. Drill lots of holes ditto. Bang chassis around. Let the smell of soldering and scorched insulation permeate the house. Study schematics at the dinner table. On the air, talk loudly about the linear you're building. After two or three weeks of this, come proudly upstairs with the new rig, or whatever. Stripped of nameplate, of course, or even without front panel. Some time later you can "acquire" a cabinet or front panel for it and,."Look, Honey, this old Collins (or Heath or Swan or . . .) panel I picked up just fits the rig. Looks real commercial, doesn't it?"

6. You need a garage or workshop where you can cache the parts of a beam for this one. Then you make a big show of going into the shop with an armload of old aluminum tubing, busted TV antennas, etc. Emerge some days later, after the usual drilling and sawing noises, with the elements of your new tri-band beauty and, "See what I lashed up. Amazing that you can do with a bunch of old aluminum." It sure is.

7. Your XYL has been bugging you about getting a new color TV. So you agree to buy one if you can have the old one for parts. Show her those great articles about how you can build a five-band KW transceiver with the parts scrounged from old TV's. You'll be surprised, and you hope she will be, too, at the nifty new rig (frequency counter, oscilloscope or whatever it is you dream of) you were able to build with those old TV parts (plus a few odds and ends from Heathkit, maybe.)

Many other suggestions for inclusion in this article were considered and discarded for such reasons as requiring outright lying, being too impractical or far-fetched, or too susceptible of detection. Others simply were variations of one or more of the above, such as disassembling a Whizzbanger 2000 at a friend's shack and then bringing it home piece-by-piece in pocket-sized components; or installing a new KWM2 in your old Viking I cabinet.

None of those so far mentioned, however, can top the one reported by a ham who of necessity shall remain unidentified here. At the time the first color TV was acquired for the family, he convinced the XYL that only a 60-foot tower and super-duper king-size antenna would bring in the color picture in their location. To this day she thinks that three-element trapped Lightningbird tri-bander is what makes Doris Day look so pretty.

The best we save for last!

Write a piece for 73 Magazine, and with the fantastic price the editor pays you for it, you buy the KW.

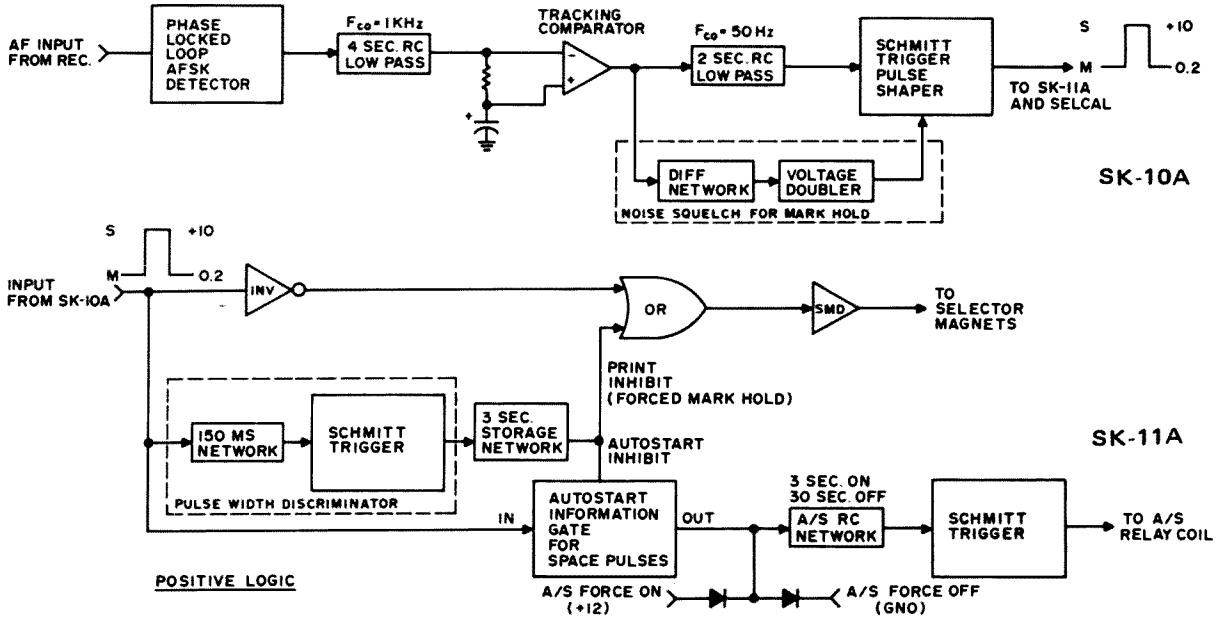
ANTI-CW AUTOSTART

An Anti-CW Autostart System for the Phase Locked Loop Terminal Circuit

A phase locked loop terminal unit has been in use in daily unattended operation on the 80 and 20 meter RTTY autostart nets for over six months with good success. The original development and operational features of the PLL TU were described in the January 1972 issue of *Ham Radio*. The detector card remains unchanged and its circuitry is shown only for the sake of continuity and clarity.

During the six months of testing it became apparent that the automatic signal acquisition and tracking (as well as automatic shift selection) capability of the PLL was not



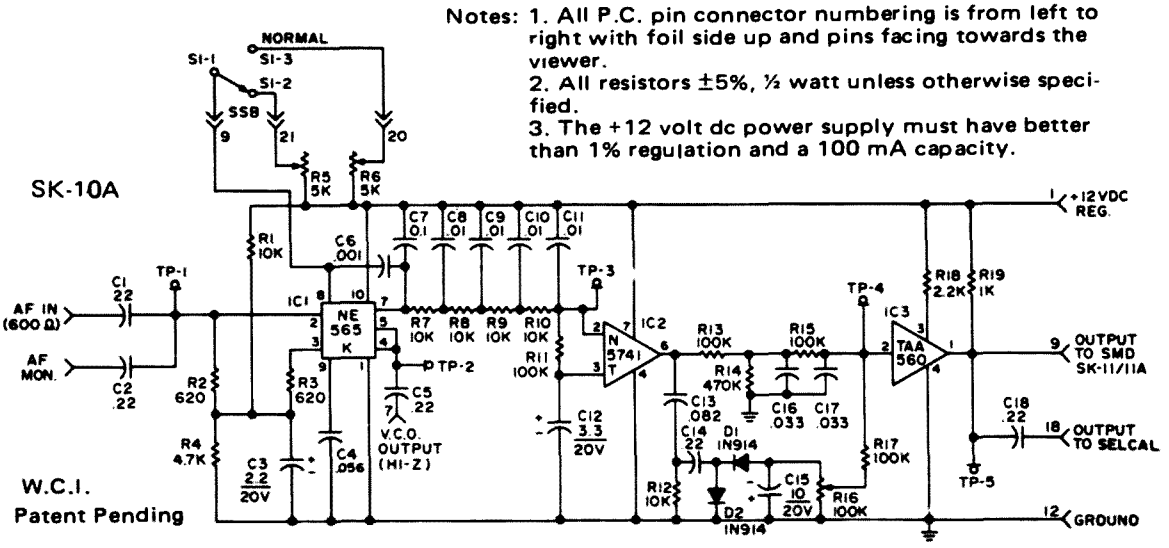


Fig. 1. Block diagram of TU.

(A) SSB mode input frequency range: 800–2200 Hz; VCO frequency set to 1500 Hz by R5.
(B) Normal mode input frequency range: 1800–3200 Hz; VCO frequency set to 2500 Hz by R6.
(C) Noise squelch adjustment R16 set for zero output at TP-5 with random noise input.

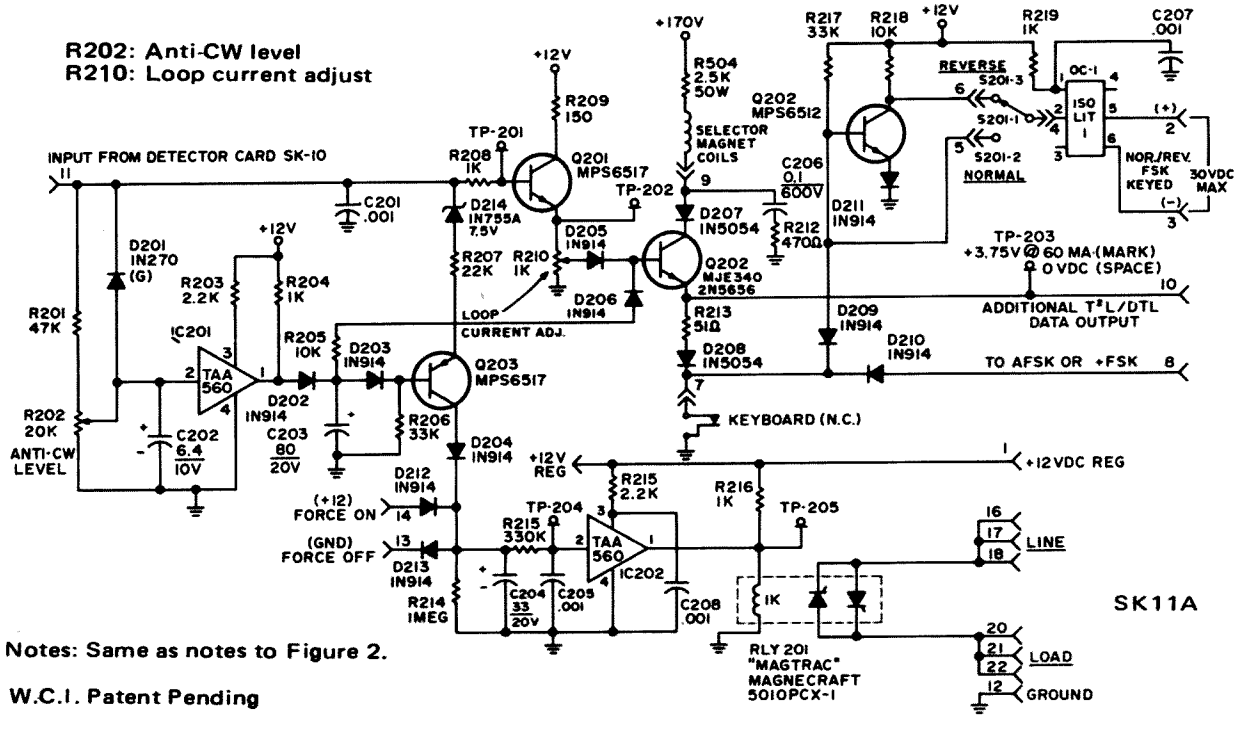
Fig. 2. Phase locked loop detector.

always an asset. In one case – that in which a CW signal came into the capture range of the loop – it proved to be a detriment. In this case the autostart would think that it was receiving valid RTTY information and cause the teleprinter motor to turn on, the result being a few feet of paper with nothing but garbage on it.

PLL AFSK Detector Characteristics

The PLL detector was designed to operate with low input tones from SSB transceivers or the normal range RTTY tone frequencies at the flip of a switch. The PLL detector would respond only to an AFSK signal that shifted higher in frequency during the space pulse. The PLL VCO normal resting frequency is set at the mid-range point of the lock frequency or capture range. If a CW signal appeared anywhere in the frequency range between the VCO resting frequency and the upper capture limit frequency the TU would lock on it as it thought it was a valid AFSK signal and it would activate the autostart. This condition will only occur when there is no valid RTTY signal present or if the CW signal is more than 8 dB stronger than the RTTY signal. The PLL has a capture effect much like that of an FM receiver.

Autostart and Selector Magnet Drive



The original autostart was activated by space pulses charging an RC time constant to a predetermined trigger level. This trigger level caused a Schmitt Trigger to fire and activate the solid state motor control relay. The mark and space pulses drove an inverter that in turn drove a constant current type of selector magnet driver. The SMD (Selector Magnet Detector) gave extremely fast rise and fall times. The selector magnet keying pulses had very flat tops and little overshoot.

Anti-CW Autostart

The RTTY character having the longest space condition is the "BLANK" key. This character has all of its 5 level 22 ms information bytes in the space condition. These, plus the start pulse, have a total space condition of 132 ms at 60 wpm (45 bauds). Therefore we can add a little safety margin and say that any AFSK signal that causes the PLL detector to go to the space condition for more than 150 ms is not RTTY. Most CW signals under 15 wpm have "Dahs" longer than 150 ms and thus would activate a pulse width discriminator. The pulse width discriminator would be set for 150 ms and be fed by space pulses. In this case the output from the PLL detector is 0 for mark and +10V dc for space. These space pulses

are fed to both the selector magnet driver inverter stage and to a voltage divider R201 and R202. The output arm of R202 is connected to C202 that is in parallel with the input to Schmitt Trigger IC201. R202 and C202 form a simple RC charging circuit that is charged by the positive 10V space pulses from the PLL detector. The time or pulse width that it takes a space pulse to charge C202 up to the Schmitt Trigger's input firing point of about +1.5V can be set by adjusting R202. The positive space pulse is also applied to D201 and reverse biases it. However when the input from the PLL detector goes to the mark condition of almost 0V dc, the positive charge on C202 is discharged through D201. This way each time a mark signal or no signal is received (there is no output from the PLL on noise because of the noise squelch), the RC timing circuit is reset to almost zero and ready to measure the next bit of space information. R202 is adjusted so that any space pulse greater than 150 ms will charge C202 to the Schmitt Trigger (IC 201) firing point. When the Schmitt Trigger fires, its positive output pulse is conducted through D202 to charge C203.

R204 allows C203 to charge through D202 in 8 ms. Even if a mark pulse is received now and the output from Schmitt Trigger went to the zero state, C203 would remain charged because D202 would be reverse biased. C203 functions as a mark-hold or non-print memory. The positive charge on C203 is conducted through R205 and D206. This forward biases the selector magnet driver (Q202) and causes current to continuously flow through the selector magnet coils. This prevents the teleprinter from printing. The same positive charge that forward biased the SMD (Q202) also reverse biases D205. This allows the mark-hold memory to override input information from the PLL detector to the SMD. Q203 is a series gate that is normally biased on. It allows the positive space pulses to flow through D214, R207, and D204 to the autostart time constant formed by C204 and R214. When enough positive space pulses charge C204 to the second Schmitt Trigger (IC22) firing point it fires and goes to the high state and turns on the solid state teleprinter motor control relay. But when C203 is charged and puts the teleprinter in the print hold condition, part of its (C203) positive charge also forward biases D203 and this reverse biases Q203. When Q203 (series gate) turns off no further positive space pulses are allowed to flow to the autostart

Notes: Same as notes to Figure 2.

W.C.I. Patent Pending

Fig. 3. Anti-CW autostart.

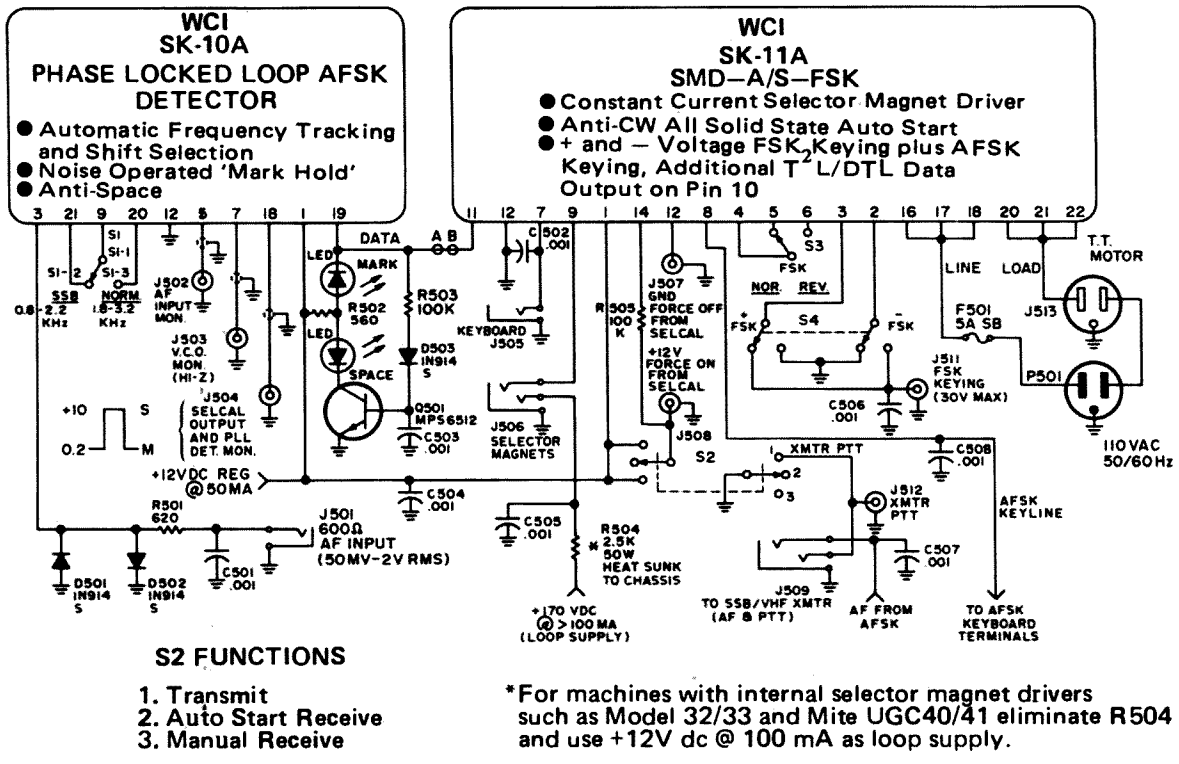


Fig. 4. Interconnect wiring.

RC circuit. Thus if the teleprinter motor is off it will stay off. If it is on, the lack of autostart positive space pulses will cause the printer motor to turn off in 30 seconds. Once the CW ceases, the TU will allow the teleprinter to go back to the print condition in 3 seconds after the last space pulse of more than 150 ms. At the same time the autostart gate is reopened.

A RTTY AFSK signal will turn the teleprinter on in 3 seconds. The teleprinter solid state motor control relay has a delayed dropout of 30 seconds. Even during this 30 second dropout time if a CW signal should appear in the upper capture range of the PLL detector the anti-CW circuit will function and place the teleprinter in a non-print condition.

AFSK–FSK Keying.

Keyboard outputs are provided to key an AFSK oscillator and an inverter option that keys an opto-electronic isolator that is used to key a negative FSK voltage. Such a voltage is found on the Signal One CX-7A. But provision is also made for keying a positive voltage FSK at the flip of a switch. The maximum voltage across the output of the opto-electronic isolator is 30V dc. An FSK reversing switch is also provided on the main frame wiring schematic.

Adjustments for the Anti-CW and SMD Card

There are only two adjustments so that a VOM and screwdriver will be all that is required. With the teleprinter connected, monitor TP-203 with the VOM and adjust R210 for a reading of 3.75V. This indicates a loop current of 60 mA. Then while receiving a 60 wpm RTTY signal, adjust R202 to the point where the machine occasionally goes into the mark-hold (non-print) mode and then back the pot off just a little. That's it; nice and simple. Now when you come back to read the copy on the teleprinter there will be no more "junque" caused by CW.

EXTRA CLASS LICENSE STUDY GUIDE

Questions & Answers Part II

21. How does the beat frequency oscillator affect the tuning of a single sideband signal?

A. Extremely. The bfo signal takes the place of the original (and suppressed) carrier, and must be properly positioned. Thus the bfo tuning and the main tuning interact. With unselective receivers, the bfo pitch adjustment may be used for fine tuning. With narrowband receivers, the bfo should be set to place its signal at the proper point on the filter's passband, and the main tuning alone used to tune in the signal.

22. Can a lossy transmission line be used to transmit signals? Explain.

A. Yes. No matter how great the loss in the transmission line, at least a small part of the original energy will appear at the load end of the line. If losses are high, however, only a very small part of the input energy will appear at the output, and line efficiency will be low. If losses are sufficiently high and the line is sufficiently long, the energy appearing at the output will be insignificant. Thus at VHF, several hundred feet of lossy coaxial cable may be used as a highly efficient dummy antenna.

23. How can you distinguish between a product and an envelope detector?

A. The presence or absence of a bfo is a sure indication, in that every product detector requires a bfo. Thus if no bfo is present, the detector must be an envelope detector. However the converse is not true; many envelope detectors have bfo's associated with them to inject a local signal into the envelope prior to detection. In general, both detectors operate in the same way: each is a non-linear mixer circuit, which demodulates the incoming signal by mixing the sidebands with the carrier. Thus when the bfo is off, a diode detector acts as an envelope detector, while with the bfo turned on, the same detector is a product detector.

24. How can a receiver be adjusted for SSB reception when the receiver does not have a product detector?

A. See question 23. Strictly speaking, if the receiver is incapable of product detection it is incapable of receiving SSB signals as such. The SSB signal can be converted into one containing a carrier by external carrier injection, using the transmitter vfo or a separate signal-frequency oscillator.

In general, however, the term "product detector" is used for a special kind of product detection circuit tailored to best reception of SSB signals; many receivers which are capable of product detection do not have "product detectors" in this sense. With such a receiver, audio gain should be turned all the way up and output adjusted by means of the rf gain control (to assure that the SSB signal is weak, at the detector, in comparison to the bfo signal). The bfo should be turned on, and the signal carefully tuned using both main tuning and bfo pitch controls until the speech becomes recognizable.

25. How do mica and paper dielectric bypass capacitors compare at different frequencies?

A. Mica capacitors have much lower internal inductance than do paper capacitors, due to differences in their construction. The difference is negligible at frequencies below the broadcast band, and may be tolerated at frequencies up to 4 or 5 MHz, but as frequency increases, the paper capacitor behaves more as a coil than a capacitor and mica or ceramic units must be used. Mica can be used into the VHF range; ceramics can be used through UHF, with care.

26. Discuss the advantages and disadvantages of electrolytic versus paper filter capacitors.

A. For the same capacitance value and voltage rating, paper and electrolytic filter capacitors compare as follows: paper is bulkier and more expensive than electrolytic, but has higher leakage resistance and much better resistance to aging. The electrolytic capacitor has many disadvantages, including low precision of capacitance value, variation of value with age and applied voltage, sensitivity to polarity of applied voltage, and a tendency to dry out. These are all, however, of little importance in power-supply filter applications. Paper capacitors may have much greater inductance than electrolytics (which may be constructed in a non-inductive manner).

27. Where in a receiver circuit should a limiter/blanker stage be placed to provide maximum utility?

A. Since the limiter/blanker circuit's purpose is to remove sharp impulse noise spikes from received signals, and such spikes cause highly selective circuits to "ring," the circuit should be placed ahead of all highly selective circuits for best results. Such a circuit usually is placed between the first mixer and first i-f strip, as a compromise between circuit ringing and achieving enough amplification to operate the blanker.

28. What frequency should a crystal oscillator circuit be tuned to for maximum stability?

A. That frequency which provides the minimum amount of feedback voltage across the crystal, while maintaining oscillation and good "starting" qualities. Usually this will be a frequency somewhat higher than the crystal's operating frequency.

29. What are microwave frequencies? What type of oscillator is commonly used to generate microwaves?

A. The term "microwave" is a loosely defined concept referring to frequencies higher than the UHF region yet lower than visible light. In general, any frequencies above 1 GHz (1000 MHz) may be considered "microwave." Another term often used now for similar frequencies is "millimeter waves," which refers to frequencies with wavelengths measured in millimeters rather than meters.

Three types of oscillators are commonly used to generate microwaves. They are the magnetron, the klystron, and the traveling-wave tube (TWT). All operate on velocity principles, rather than the intensity principles used at more familiar frequencies.

30. What are some of the factors that affect the field strength of a signal from a radiated antenna?

Field strength is influenced by many factors. A primary factor is the amount of power applied to the antenna for radiation. Another is the distance between antenna and measuring point, since field strength falls off as the square of the distance. Still another is the directional pattern of the antenna, which determines what proportion of the applied power is radiated in any specific direction. Reflections and multiple transmission paths can cause variation of field strength with small changes of measurement position, and both atmospheric and ionospheric conditions can cause field strength to vary from day to day. Signal frequency plays a large part in determining how the other factors affect field strength. For this reason, field strength is almost impossible to predict, and must be measured for an accurate determination in any specific case.

31. What factors determine the frequency at which a quartz crystal will oscillate? List some of the advantages of using crystals in amateur equipment.

A. A quartz crystal's oscillating frequency is determined primarily by physical

dimensions of the crystal and by the "mode" of mechanical flexure within the crystal itself, and also may be modified by temperature and by the external circuit to some degree.

The major advantage of using crystals in amateur equipment is that it provides the most stable resonator yet known, so that oscillation remains on the same frequency for the same crystal within very narrow limits. Other advantages include ease of frequency determination and the ability to switch from one operating frequency to another and return without tedious adjustment, by replacing one crystal with another.

32. Explain the properties of a quarter-wave section of rf transmission line. How would these properties change if the output ends of the section were short-circuited?

A. An open-circuited quarter-wave section of rf line has the properties of a series-resonant LC tuned circuit. That is, its impedance between terminals is very low (nearly a short circuit). Apparent Q of such a resonator is very high, and tuned lines are used in VHF transmitters as tank circuits.

A shorted quarter-wave section reverses its characteristics to those of a parallel-resonant LC tuned circuit, and offers high impedance (nearly open circuit conditions) at its input terminals. Such a line may be used as an insulator.

A quarter-wave line connected between two different impedances acts as an impedance transformer; the output impedance for matching conditions is equal to the line's impedance, squared, divided by the input impedance value. Conversely, line impedance in order to match must be equal to the square root of the product of input and output impedance values.

33. How should a wave trap be connected to a receiving antenna circuit to attenuate an interfering signal?

A. A parallel-tuned wavetrap should be connected in series with the antenna and receiver so that all incoming signals must pass through the parallel-tuned circuit before reaching the receiver. A series-resonant wavetrap should be connected across the

receiver's input terminals in parallel with the antenna, so that it shorts out the undesired signal. Both types of wavetraps may be used at the same time if desired. At VHF and above, quarter-wave line sections may be used as wavetraps (refer to question 32 for parallel between line sections and tuned circuits).

34. Why are synchronizing pulses transmitted with television signals?

A. To assure that the horizontal and vertical sweep rates at the receiver are the same as those at the transmitter, thus making certain that the electron beam is at the same spot on the picture tube face as compared to the camera's scanning beam at each instant during the transmission.

35. How may an amateur check his transmitter for spurious sidebands?

A. By use of a selective receiver. The transmitter should be operated at minimum power into a dummy load to avoid overloading the receiver's input circuits, and the receiver then tuned over a wide range (several kHz) either side of the transmitter's signal while normal modulation is applied. Spurious sidebands will appear as "splatter" or "buckshot," coinciding with voice peaks usually but not necessarily.

36. How can the safe power input to a crystal oscillator circuit be determined?

A. The "safe" power input, not to be confused with the "proper" power input, may be determined by operating the oscillator at various power levels, increasing power each time, and observing the output signal for 30 seconds or more at each level. When power input approaches the "unsafe" region, the heat generated in the crystal will cause its dimensions to change, thus making its output frequency drift. The more unsafe the condition, the more rapid the drift of frequency. "Proper" power input is well below the unsafe level; it is the minimum which will produce reliable oscillation.

37. Define the term decibel. How is the decibel used for voltage and power calculation?

A. The decibel is one-tenth of a "bel." The "bel," in turn, is a measure of the ratio between two power levels, and is the logarithm (to base 10) of that ratio. The mathematical formula defining the decibel (abbreviated dB) is:

$$dB = 10 \log_{10} \frac{P_2}{P_1}$$

DB are used to compare voltages, but the comparison is meaningful only when the voltage is converted to a power level unless both voltages appear across the same impedance. If both voltages appear across the same impedance, dB can be used with voltage ratios. Since power varies as the square of the voltage, the square of the voltage ratio must be used. This is accounted for in the formula by multiplying the log by 2, to produce the familiar 20-time factor.

A dB value of "0 dB" indicates that both powers are the same, or both voltages. a 3 dB ratio indicates that one power is twice the other, or one voltage is 1.414 times the other. A 6 dB ratio indicates 4 times the power or twice the voltage. A 10 dB ratio indicates a 10-to-1 power ratio or 3.16228-to-1 voltage ratio. A 20 dB value indicates a 100-to-1 power ratio or 10-to-1 voltage ratio.

The usefulness of the dB system of measurement lies in the fact that it measures a ratio rather than absolute values, and almost all measurements and calculations to which it is applied are affected much more by ratio than by absolutes.

38. How are the emitter, base, and collector of a transistor biased for amplifier operation? How are they biased for cutoff (open circuit) and saturation (short circuit)?

A. For amplifier operation, the base-emitter junction of the transistor must be forward biased (conducting) while the collector-base junction is reverse biased (non-conducting). Bias values and the amount of current injected into the base-emitter junction are chosen so that conduction occurs between collector and emitter, and the amount of conduction which occurs is determined by the value of base current.

In switching operation, to achieve cutoff the base-emitter junction is reverse biased (non-conducting) which blocks vir-

tually all conduction in the collector-emitter circuit. Saturation is obtained by forward bias of the base-emitter junction, with injection of maximum current. In both cases, the collector-base junction is reverse biased.

Note that the only difference between amplifier operation and the saturation condition is the amount of current injected into the base-emitter junction. With some types of transistors, no reverse bias is necessary to achieve cutoff; merely reducing the injection current to zero does the job.

Transistors designed for amplifier use are built to operate best in the transition region between cutoff and saturation; those designed as switches are built for minimum resistance in saturation with maximum resistance at cutoff, and properties in the transition region may be neglected. However many devices designed for one purpose work well for the other, and vice versa.

39. How do NPN type transistors differ from the PNP type? How does their bias differ?

A. Transistors always consist of two types of semiconductor material in three regions, forming the emitter, base, and collector. The types of material are "N" type, which has an excess of electrons, and "P" type, which has a shortage.

An NPN transistor uses N-type material for emitter and collector, with P-type for the base. A PNP, on the other hand, uses P-type for emitter and collector, and N-type for the base.

Polarity of all bias connections is reversed from one type to the other. For instance, an amplifier circuit in the conventional common-emitter configuration may have the emitter grounded, with negative bias going to both collector and base through appropriate resistors, to establish the required bias conditions for a PNP transistor. If an NPN is used in the same circuit, the bias polarity must change from negative to positive.

40. How can the output circuit of a transmitter be adjusted to increase or decrease its coupling to the antenna system?

2 meter FM Mobility at unheard-of Savings

AVCOM FM-201 SOLID STATE TRANSMITTER MODULE

Starts You on Your Way!

Only $49.95 COMPLETE – Not a Kit 90-Day Warranty

- Ideal for Repeater use! Just add ant., mike, Xtal and 12-16 volts DC.
- Cut Transceiver cost as much as 50%. Add police band receiver to AVCOM FM-201 Transmitter. Your rig can cost under $100 while others are priced up to $250.
- Already have a 2 Meter FM rig? Increase your fun, save installations and removals of your high priced mobile rig with a low-cost second rig.
- Walkie-Talkie compactness — glass epoxy printed circuit board is only 3" x 3½".

SPECIFICATIONS:
Mike Pre-Amp: high impedance input, integrated circuit.
Operates anywhere between 12 and 16 volts DC.
4.0 kHZ frequency deviation typical. 1-Watt DC input to final transistor

Order Your FM-201 Transmitter Module Today!
LM-210 10 Watt POWER Amplifier Module $29.95

of man-made signals such as "ignition noise" or the "static" caused by sparking at the contacts in electric motors. Electrically, however, these are signals; "noise limiters" deal with these unwanted signals, which are most usually generated by the sudden interruption of current flow which may or may not be accompanied by a visible spark.

Natural "noise" is a random change of energy level, which is more or less evenly distributed across the electromagnetic spectrum, and is not "coherent" (that is, it has no specific frequency as such). In the audio range, it manifests itself as a hiss or frying sound.

Such noise is basically due to the statistical unpredictability of energy-level changes within the individual atoms which go to make up the universe, and because of this is always present. In amateur practice, it is generally characterized by its apparent origin. Thus we have, for example, "antenna noise" which is present with the signal when it arrives from the antenna. This is, in turn, composed of "galactic noise" which arrives from outer space, "atmospheric noise" which originates within our own atmosphere and ionosphere, and "thermal noise" which originates within the conductors of the antenna and feedline (as well as within the components of the amplifier's first rf amplifier stage). Noise of this sort is always proportional to temperature; the higher the temperature, the greater the noise voltage. In fact, in radio astronomy noise levels are measured in "degrees Kelvin" which are a measure of the temperature of the apparent noise source.

Besides antenna noise, we have "receiver noise," which includes thermal noise in the components ahead of the first rf stage, "shot noise" in the tube or transistor of the first stage, "partition noise" from multi-grid tubes in the rf amplifier chain, and "mixer noise" contributed by the mixer stage(s).

All these noise voltages, except for man-made "noise" signals, are very low, but with the high amplification available in most receivers, provide a lower limit to the receiver's sensitivity.

A. The output coupling adjustment depends upon the type of output circuit used. A pi-network output circuit's coupling is determined by the output capacitor; the more capacitance, the less the coupling. A link-coupled circuit is determined by physical coupling of the link to the final tank; the closer, the greater the coupling.

41. How do filters attenuate harmonics emissions?

A. We assume that the question refers to low-pass filters, since high-pass filters would not attenuate harmonics, and a bandpass filter would reduce harmonics in the same way as does a low-pass unit.

The filter consists, then, of one or more sections which contain series inductance and shunt capacitance. Reactance of the inductance rises with frequency while that of the capacitance falls. The harmonics being at a higher frequency than the desired signal, their energy is opposed by the increasing reactance of the inductance, and finds a ready path to ground through the reduced reactance of the capacitance.

In some cases, resonant circuits are employed to trap out specific harmonic frequencies. Refer to questions 32 and 33 for discussion of wavetraps.

42. List several advantages and disadvantages each for Class A, Class B, and Class C amplifier operation.

A. Class A offers greatest linearity (least distortion) and simplest adjustment during operation, but is least efficient in use of input dc power and is limited in power-handling capability.

Class B offers improved efficiency and power output capacity, but at the cost of increased distortion and critical adjustment.

Class C has highest efficiency and relatively uncritical adjustments, but inherently distorts the signal and so cannot be used when the signal envelope must be preserved. It also produces much greater harmonic output.

43. What are some different types of noise voltages encountered in amateur receivers? How is each type generated?

A. The word "noise" may be misleading, because much "noise" actually consists

FOR THE PROFESSIONAL AMATEUR

SONAR (2 meters) TRANSMITTER RECEIVERS (from 144 to 148 MHz)

COMPLETE FLEXIBILITY FOR FOR MOBILE — BASE — HAND HELD

model FM3601 — 10 WATTS

- 8 Channels with Instant Push Button switching
- Solid State—using the finest quality silicon transistors
- Netting trimmer for each receive and transit crystal
- High quality mechanical filter for adjacent channel rejection
- Military-grade, glass-epoxy printed circuits
- Rugged, serviceable design - Compact, but not crowded
- Quick removal tray mount for security
- 25 transistors, 1 IC, 1 MosFet, 16 Diodes
- Receiver R.F. stage protected from overload
- Diode protected Dual-gate FET mixer
- Dual vari-cap phase modulator

$290.95

Complete with microphone, mobile mounting tray and 2 pair of crystals, (146.94T/146.94R and 146.34T/146.94R)

44. What are current and voltage characteristics along a transmission line when it is matched and mismatched?

A. Assuming that the line has losses so low that they may safely be neglected, in a matched line the current will be the same at any point, and so will the voltage.

When a mismatch exists, the current and voltage values will vary cyclically along the line, repeating every half-wave along the length of the line, and current and voltage will not necessarily be in phase with each other. The ratio between minimum and maximum is expressed as "standing wave ratio," and is proportional to the ratio of mismatch. That is, a 50Ω line terminated in 100Ω will display a 2-to-1 ratio between maximum and minimum voltage, and has a VSWR of 2.0.

45. How do receivers for remote control of objects and regular type communications receivers differ in basic operation?

A. Normal communications receivers are intended to provide information to human beings, and normally do so in the form of audio signals through headphones or loudspeakers (although an RTTY station does so via printed words on paper). Remote-control receivers, on the other hand are intended to provide information to machines to control their actions, and normally do so without output transducers such as phones, speakers, or printers, by means of electrical signals which directly actuate the controls.

In addition, communications receivers usually offer continuous tuning over several frequency bands, if not the entire spectrum, while remote-control receivers are usually fixed-tuned on a limited number of channels. However, some commercial communications receivers (such as those used in aircraft communication) are fixed-tuned, while nothing prevents incorporation of continuous tuning in a remote-control receiver. The output-signal distinction is the defining difference in characteristics.

This marks the half-way point in the FCC study list. Questions 46 through 90 will be continued in June *73*.

A MODERN VHF FREQUENCY COUNTER

Part 1 of 3 parts

Frequency counters have been finding their way into more and more ham shacks since two-meter FM activity made accurate frequency measurement a must. Even some sideband equipment now comes with digital frequency readout.

Although a number of frequency counter designs have appeared in *73* and elsewhere, we decided it was time to come up with a new design. We have gone out of our way to make the building of this counter as easy as possible, and yet to produce a counter of really top-notch performance. The complete information you need to build your own counter will be presented in three parts. This month we will give a complete description of what the counter is and what it can be used for, as well as the complete parts list so you can start collecting parts if you decide to go ahead. Next month we will give the complete logic diagrams and theory of operation. The month after that we will have the printed circuit board layout, parts layout drawings, and construction and operating information.

And now a little information about the counter:

1. The basic counter measures up to 20 MHz, although many IC's go past that. One of our prototypes goes up to 35 MHz, and the other goes to about 40 MHz. But that's only the basic counter – an optional VHF pre-scaler mounts on the same board and extends coverage to above 200 MHz. Depending on the IC's, you may get operation higher than that. We've had our prototype counting at the upper limit of our signal generator, which is 250 MHz. With a simple modification, the scaler range can be increased to typically 320 MHz though at reduced sensitivity.

2. It is easy to build. Except for the power supply, all other small parts fit onto one 7 x 10 in. printed circuit board. This means there's a minimum of external wiring and less chance for error. The p.c. board layout, etched boards, and complete parts kits are available to make the job even easier.

3. The resolution is within 1 Hz with the basic counter up past 20 MHz, and within 10 Hz with the VHF scaler. The accuracy depends on the quality and type of reference crystal used; the circuit allows you to zero-beat the crystal against WWV. With the AT-cut series-resonant crystal suggested the specs say that the drift should be less than 0.5 parts per million (ppm) per month (equivalent to about 75 Hz at 2 meters) and

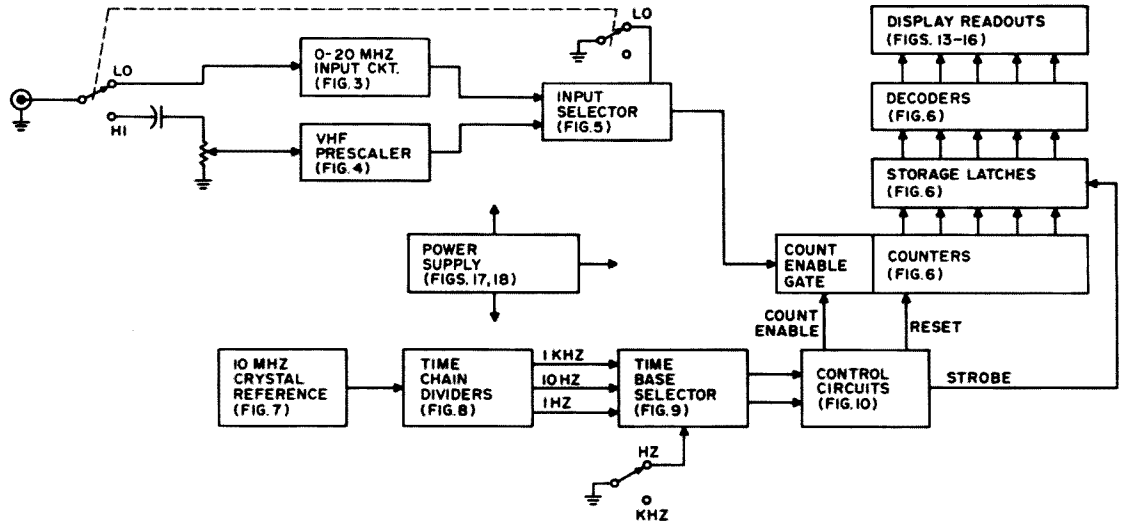

Fig. 1. Counter block diagram.

the temperature coefficient should be about 0.077 ppm per degree Centigrade (about 12 Hz at 2 meters). In our counter the crystal is mounted close to the edge of the p.c. board with the idea that someday we will place it in a crystal oven. Let's face it – the measurement accuracy is only as good as the reference crystal accuracy, and all the really expensive commercial counters have crystal ovens. (The Heathkit doesn't and it drifts with temperature.) Although we will not describe an oven in this article, we suggest you keep it in mind for that certain "someday."

4. The design is really up to date. It uses the latest TTL and ECL integrated circuits. To simplify construction, complex MSI (Medium Scale Integration) IC's are used to reduce the number of interconnections. Although the board is laid out for Numitron readout tubes, light-emitting-diode (LED) readouts can be used to provide state-of-the-art reliability as well as really snazzy looks.

5. The price is really reasonable. Complete with all parts, including cabinet line cord and all the other necessary things so often forgotten in parts estimates, the entire counter *with* VHF prescaler will cost you about half of what you'd pay for the cheapest commercial units, including kits. Here's how the price breaks down into the various portions of the counter.

a. Basic counter circuitry including all IC's and small parts, but not including VHF prescaler, readout indicators, and power supply – about $65.

b. Power supply – about $15.

c. VHF prescaler, optional – about $25.

d. Readout indicators and associated circuitry.

The price depends on which indicator type you choose. Numitron readouts will add about $25, miniature incandescent readouts (sometimes called Minitrons) will cost about $20, and LEDs will cost about $35 (prices from one source dropped to $6 per LED at the time of writing, and we expect other dealers to follow suit.) Though the Minitrons are the cheapest, we don't really recommend them since the $5 saving over Numitrons doesn't justify the added work. Numitrons are viewed from the side, and plug right into the p.c. board. In this way you can read the digits from the front of the board. The Minitrons, on the other hand, are viewed from the top. This means you need a separate p.c. board, mounted at right angles to the main board and in front of it, to provide a convenient readout. Those two boards will connect to each other with 38 wires! Incidentally, the LEDs mount the same way, but that's the price of progress.

e. Cabinet, input connectors, test leads, assorted hardware etc. – about $15.

These prices assume you have to go out

and buy all new parts, though not necessarily from a dealer who charges list price. Quite a few of the IC's are available at below-cost prices from a number of mail order outlets around the country, and we used these prices in calculating the total price.

If you have a modest sized junk-box, you may be able to shave these prices a bit, but don't expect miracles. Unless your junk-box is very modern, it probably won't contain too many useful parts aside from things like switches, connectors, fuse and line cord, and the like. Still, it seems quite reasonable that with a little effort you could build the complete counter with Numitron readout but less VHF scaler for less than $100, and for about $125 with it. This is roughly half or less of the price of the Heathkit counter or counter/scaler combination. And it isn't much more than some commercial VHF scalers alone.

Interested? Then let's get on with the description. Figure 1 shows a fairly complete block diagram of the entire counter. The individual diagrams for each block will be shown next month, and the block diagram gives the figure number for the detailed diagram.

The input signal is fed by the HI-LO switch to either the 0–20 MHz input circuit, or to the VHF prescaler. The low frequency input circuit just converts the input signals into digital pulses, while the VHF prescaler divides the input frequency by 10 to bring it into range of the rest of the counter circuitry. The outputs of these two circuits are sent to the input selector, which selects one input and sends it on to the count enable gate, which is part of the counters. The count enable gate is opened by the control circuits for a specified length of time, and the number of cycles during that time is counted by the counters. The count is then transferred into the storage latches, which hold the count while the counters take the next count, to produce a non-flickering display. The output from the storage latches goes to the decoders, which then feed the display readouts. The display shows a five-digit number and has an over-range light if the count exceeds five digits.

The time reference for the count enable gate comes from a 10 MHz crystal oscillator,

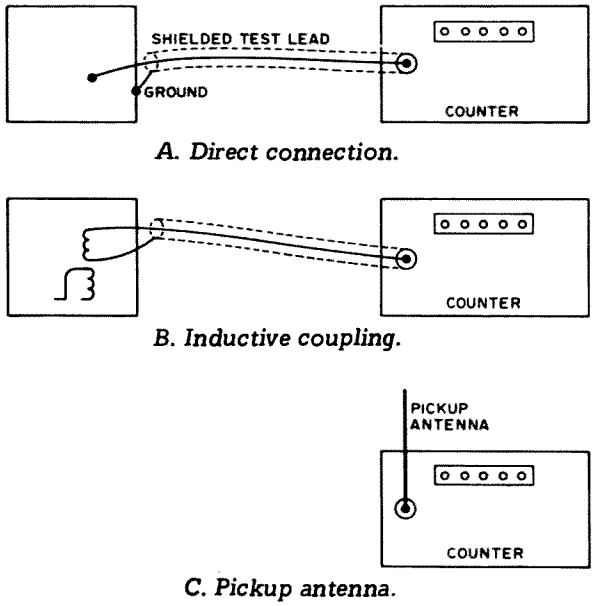
whose output is divided by seven decade counters in the time chain divider circuit, to produce 1 kHz, 10 Hz, and 1 Hz pulses which go to the time base selector. The selector chooses the correct frequency pulse train, and sends it to the control circuits.

The control circuits govern the basic timing of all functions of the counter, and generate the count enable, strobe, and reset signals, in that order, over and over. Thus the counters are allowed to count for a certain amount of time, then the count is transferred (strobed) into the storage latches, the counters are reset back to zero, and then the count enable comes again for the next count.

One of two measurement periods is selected by the Hz-kHz switch. Assuming that you are not using the VHF scaler, the Hz position of the switch results in a count enable signal lasting exactly one second. Thus the counters count the input frequency for exactly one second, and the five-digit display then shows the right-most five digits of the total count, up to a maximum of 99999. If the actual input frequency is higher, the readouts still show the right-most five digits, but an over-range light indicates that there are more digits to the left. For example, suppose the input frequency is 1,234,567 Hz. Then the readout shows the digits 34567 and the over-range light is on.



If we want to see the digits to the left, we just move the switch to the kHz position, which selects a count enable period of 1/1000 second (1 millisecond). If the input frequency is 1,234,567 Hz, then there will be 1,234 cycles in that millisecond, and the readout will show the digits 01234. Put the two readings together, and you have a readout down to the last cycle.

Top view of counter.

Using the VHF scaler, all input frequencies are divided by 10. For example, if we want to measure a 146.940123 MHz signal, the scaler converts the frequency to 14.694012 MHz. In the kHz position of the Hz-kHz switch we will have a readout of 14694, while in the Hz position we will get 94012 with the over-range lamp lit. Thus we have resolution down to 10 Hz.

While it may seem a bit inconvenient to have to use two readings to get an accurate frequency indication, there are two good reasons for doing it this way. First, to get the frequency in just one reading, we would need an 8-digit readout instead of five. That means three more counters, three latches, three decoders, and three indicators. That's an increase of 60% in price in that part of the counter. If price is no object, it's easy to add the extra parts yourself.

A. Direct connection.

B. Inductive coupling.

C. Pickup antenna.

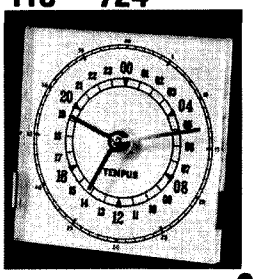
Fig. 2. Coupling the counter to external equipment.

The second reason is that to get an accurate readout down to the last cycle (or last ten cycles with the VHF scaler) takes a whole second of counting. If you don't need that accuracy, that's a relatively long time. In the kHz position we get a new reading every 1/10 second, which really speeds up the process, especially if the frequency is changing and you want to follow the change.

Before we get on to the parts list, it might be a good idea to look at some applications of the counter. Figure 2 shows some typical

ways to connect the counter to a circuit to measure the frequency of a signal. Just because measuring the frequency of a 2-meter FM rig is the most obvious, we'll leave that for last.

Figure 1A shows the easiest way - connecting directly into a circuit. The low-frequency input circuit on the counter has an input impedance of about 1 MΩ, shunted by less than 20 pF, approximately. The VHF scaler has an input impedance of 50Ω. But avoid overdriving the inputs to avoid damage. The low-frequency input can stand voltages up to about 100V peak, though it may not count well at inputs over 20V. The VHF input uses a 50Ω attenuator, and you should make sure not to overdrive the input stage, since this may damage the input circuit or slow it down (for highest speed it's necessary to keep the input transistors from saturating, which means keeping the level just above the point where the counter just starts counting). The best habit here is to start with the attenuator at minimum and turn up just enough to get a good reading.



It's hard to give a sensitivity figure for both inputs since we don't have voltmeters capable of measuring at rf frequencies. But it appears that the low-frequency input needs about 200 mV rms, and the VHF input needs about 400 mV. Incidentally, both inputs have input isolation capacitors, so the counter can be connected to a point where a small dc voltage is present. But watch out, and don't exceed the breakdown voltage of the capacitor you use. This limits the low-frequency input to frequencies above about 20 Hz; if you want to go below that you will just have to increase the value of the isolation capacitor, or remove it altogether.

Using the direct connection, we've been able to measure the frequencies in tube-type equipment as well as low-level transistor circuits. But don't try to connect the counter to your power amplifier! A very useful way of putting 2-meter gear on frequency has been to connect the counter to the output of the oscillator, and measure the frequency right there.

When you have a high-power stage, or a stage where you don't want to make a direct connection, the best way is with an inductive loop as shown in Fig. 1B, much like a

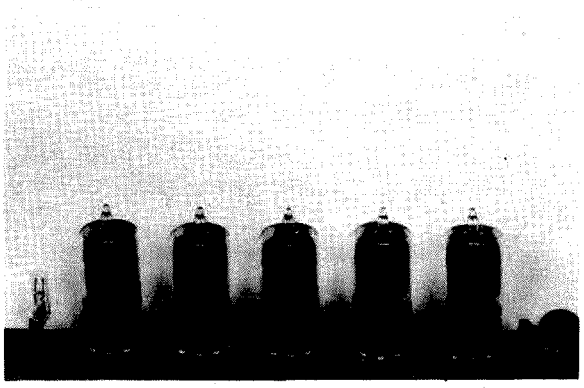
wavemeter would be used. If you are working with a high-power stage, start with the counter loop far away, and only gradually bring it closer until you just get a reading. A very useful coil to use as the pickup loop is a coil from a grid-dipper (GDO).

Incidentally, we have found that the counter makes the GDO into an extremely useful device. The problem with most GDOs (and signal generators as well) is that their frequency calibration is terrible. But the counter solves all that – just take the next higher frequency GDO coil, connect to the counter, and use as the pickup loop, an inch or so from the GDO coil. By measuring the actual frequency your GDO is putting out, you can align a tuned circuit right on. To find out the frequency of an unknown received signal, just beat the GDO against it and read the frequency. If the GDO doesn't go that high, use a harmonic. For example, we wanted to find out the frequency of a signal in the 160 MHz public service band. We tuned in the signal on a cheap VHF monitor radio, beat the tenth harmonic of a 16 MHz signal from the GDO against the unknown, and read the 16 MHz frequency on the counter. Multiply by ten, and you have the right value, and you don't even need the VHF scaler.

Another application along the same line comes when you have a real low-level stage, where there just isn't enough signal to count the frequency directly with the counter, or where there are several frequencies at the same time, as in a reflex amplifier. We solved that by plugging an earphone into the GDO, zero-beating it against the unknown, and reading the GDO frequency with the counter.

Finally, Fig. 1C shows how to measure the frequency of a transmitter – just connect the counter to another antenna near the transmitting antenna. We've used this approach at 2 meters, with a 19-inch piece of wire connected to the counter. We've been able to measure the frequency of a 1W handie-talkie about five feet away, which shows that the sensitivity is quite good.

To end the overall description of the counter, the parts list provides a complete list of everything you need to build the counter. The parts list is divided into 5 parts.



LED readouts.

Part A has all the basic counter parts except for the readouts, the VHF scaler and the power supply. All of these parts fit on the main 7 x 10 in. printed circuit board, except for the Hz-kHz switch which mounts on the front panel.

Part B describes the power supply, which provides a regulated +5V ±5% at about 1.5 amperes and +25V unregulated at about 10 mA. There's quite a bit of room for experimentation here, but make sure that the +5V supply voltage is well regulated. The diodes and filter capacitor for the +25V supply mount on the main p.c. board, but the +5V supply mounts separately. We did not design our own p.c. board for the +5V supply, since a number of commercial supplies and kits are available.

Part C describes the optional VHF scaler. Except for the 50Ω input pot and the HI-LO switch, all of these parts also fit on the main p.c. board, and can be added at any time.

Part D lists the parts for the readouts, with a choice of either Numitron, Minitron, or LED readout. (You could substitute NIXIE® tubes, but then you'll have to redesign the p.c. board since different IC decoder/drivers are needed.) The Numitron

Numitron readouts.

VHF - FM

Solid state modules for VHF and FM Construction. All modules are completely wired and tested for twelve volt negative ground operation. They are constructed on G-10 glass boards using the latest in solid state and IC design. Average size of board is 1½ X 4 inches.

- **RF-144** Single channel front end using two dual gate Mos-fets and two bipolars contains five capacity tuned RF circuits and a netting trimmer across the crystal.
- **RF-220** Same as RF-144 except for 220 MHz use.
- **IF-10.7** A 10.7 MHz IF amplifier with a 455 kHz converter. Contains two ICs, one crystal and five tuned circuits.
- **FM-455** A 455 kHz IF amplifier, limiter, and quadrature detector with two ICs and four tuned circuits. This may be used with any 455 kHz IF Receiver. Narrow band can be made wide band if desired.
- **AS-1** One watt audio amplifier, squelch. Contains two ICs.
- **TX-144** One watt FM exciter with audio limiting, phase modulator, adjustable deviation, and netting trimmer. Contains one IC and four transistors.
- **TX-220** Same as TX-144 except for 220 MHz.
- **PA-144** Ten watt amplifier for above exciter using two power transistors designed for misload protection.
- **PA-220** Same as PA-144 except for 220 MHz.

Prices start at $19.95. With a complete transceiver under $130.00. Circuit boards and parts kits available. Write for prices. Receiver modules $19.95. Transmitter modules $39.95. Power Amp modules $29.95. Complete manual covering all above boards with parts list, layout and schematic $1.00. Prices do not include crystals or shipping. Write for free brochure.

VHF ENGINEERING W2EDN

1017 CHENANGO ST. BINGHAMTON NY 13901

readouts mount right on the main board, using 9-pin miniature tube sockets.

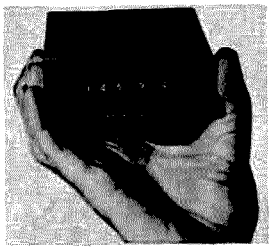
Minitron and LED readouts need a separate board to hold the readouts. For the Minitron you can use perf-board with holes on 0.1" centers. The LED readout, however, needs 150Ω current limiting resistors, and so we have designed a 3 x 7 in. p.c. board to hold the five LED readouts, the current limiting resistors, and a single red LED diode for the over-range indicator.

If you use the Numitrons or Minitrons, you will need a separate 3V lamp power supply, as well as a driver transistor for the over-range lamp. Except for the lamp supply power transformer, all other components mount on the main p.c. board.

Finally, part E of the parts list gives some of the miscellaneous parts you will need to complete the counter. As far as the cabinet is concerned, you're on your own. Our prototype (shown in the photos) used a Bud "Tilt-a-View" cabinet (TV-2155) but this cabinet is a lot bigger than you need. We wanted to leave everything open so it would be visible on the photos, but the counter can be crammed into a small cabinet, with the power supply stacked above or below the main board.

Next month we will continue with more information. . . .K2OAW

FREQUENCY COUNTER PARTS LIST



A. Basic counter – less readouts, scaler, power supply

12	SN7490N	TTL decade counters
4	SN7400N	Quad 2-input TTL nand gate
5	SN7475N	Quad TTL latch

THE VANGUARD FREQUENCY SYNTHESIZER

YOU'LL NEVER HAVE TO BUY CRYSTALS AGAIN

MODEL ST-140. Size: 1½" HIGH X 3 5/8" WIDE X 8" LONG. PRICE: $119.95 ppd. NOTE: NY State residents add sales tax.

- 1000 channels from one crystal (yes, that's one thousand) selectable every 10 KHz. from 140.00 to 149.99 MHz.
- Better than .0005% (5 parts per million) from −10° to +60° C down to −30° C with accessory heater available later.
- Thumbwheel switches with digital readout for fast selection.
- Uses a super precision crystal reference source operating at 5 MHz. for easy checking with WWV. RF output is obtained from a VCO tightly locked to the reference source in a digital phase-locked loop circuit.
- Present model is available with output in the 6, 12 or 18 MHz. band (corresponding to 144 MHz.) for direct substitution of transmitting crystals. Built-in computor selects the appropriate frequency when you set the readout to the transmitter output you want.
- Changes frequency almost as fast as you can switch. Settling time is in milliseconds even when switching from one band limit to the other. No hunting or false locks as with some other synthesizers.
- Operates from 10 to 15 VDC. Includes 3 precision IC voltage regulators (one for each major circuit function) to prevent interaction and to take care of those wide voltage swings in mobile installations. Can also be used on 110 volts AC with a small 12 volt 1/2 amp power supply.

COMING SOON: A frequency synthesizer for 45 MHz. receive crystals, a combination transmit and receive synthesizer, a synthesizer with direct output in the 144 and 220 MHz. band, and a whole series of synthesizers to cover from sub-audio to microwave frequencies.

IMPORTANT: When ordering be sure to state if you want the 6, 12 or 18 MHz. output.

D. Readout Indicators – choice of D-1, D-2, or D-3

D-1 Numitron Readouts

5	DR-2010	RCA Numitrons
5		9-pin p.c. mount tube sockets
1*	5V 30 mA	bulb (Sylvania 5ESB or equiv) with matching lampholder and lens
1*	6.3V 1 amp	filament transformer (center-tapped)
2*	1 amp 50 PIV	rectifier diodes
1*	10K	¼W 10% resistor
1*	2N5172	NPN transistor or equivalent

D-2 – Minitron indicators

5		Minitron readouts
5		16-pin IC sockets

Plus all starred components from D-1 above, and a circuit board.

D-3 – Light-emitting-diode readouts

5	LED	Readouts. (Monsanto MAN-1 or MAN-3, Litronix 10A, Environmental LED-700, or equivalent)
35	150Ω	¼ watt resistor 10%
1		red LED overrange indicator
1	220Ω	¼W 10% resistor
50		MOLEX pins
1	3 x 7 in.	p.c. board for LED readouts

E. Miscellaneous

Cabinet – Input connector – Test leads – Line cord strain relief – Bezel or polarized glass in front of readouts – Hardware.

NOTE: Board layouts are available from the author. Etched and drilled boards are available from Ionic Industries, Criss Circle, Elk Grove Village, IL 60007. Boards, IC's and other parts are available from Circuit Specialists, Box 3047, Scottsdale, AZ 85257: $70 for drilled PC board, IC's and all active devices.

EXTRA!

OSCAR MARINER ONE IS ON THE PLANET MARS

by Keith E. Lamonica W7DXX, special to 73 Magazine

Well it took a long time but OSCAR Mariner 1 is now on the planet Mars and operating well. As you recall, space became available for the OSCAR package on the last unmanned NASA mission to Mars. Dr. Bernard Wizenhoff called OSCAR headquarters and told the group the good news. He said, "Gentlemen, we are launching Mariner 34 to the planet Mars when the next launch window is available for the shot. It will be between January 11 and 18th. We will place three Bromar type capsules in synchronous orbits around the planet and an LSVL (Life Support Verification Lab) on the planet's surface near the Nodus Gordii crater complex." Dr. Wizenhoff continued, "We have room for a 12-pound package from the OSCAR boys."

Dr. Wizenhoff and NASA had given amateurs around the world a chance to study Mars. However, a great deal of work had to be completed in a short period of six months. It had been hinted three years ago that space on a Mariner mission would become available so a great deal of thought had been put into a possible OSCAR mission to Mars. These were to be the main objectives of OSCAR Mariner 1:

1. The capsule would have a 450 MHz beacon transmitter on 444.1
2. The capsule would have a 1250 MHz to 144.1 repeater
3. The capsule would incorporate a general coverage receiver that would automatically scan from 500 kHz to 10 MHz and retransmit any signals found to 1250 MHz
4. The capsule would make use of a small atomic generator donated to OSCAR by NASA.
5. The capsule would transmit slow scan video signals during approach, descent, and after landing on Mars.

This was to be an extremely ambitious program that looked good on paper and would now be put to the test. OSCAR Mariner 1 had to be designed, built, and ready for launch in *six months*.

Howard W6UOV and his group would concentrate on the 450 beacon and 1250 to 144 repeater. The boys at OSCAR in Europe would design and build the general coverage receiver with auto scan. The engineers at NASA agreed to install the atomic powered generator and television camera. We were informed that the television camera would be on loan only. I can't figure out how they intended to get it back since all manned flights to Mars had been cancelled after the strange goings on with the manned Mariner 16 and 21 missions. As you recall, NASA cancelled all manned flights to the surface until a more complete study could be made of the strange lights and mental confusion. The crew of Mariner 16 had an excellent flight to Mars and everything went very well until their first rest period while in a parking orbit around the planet. The crew was awakened from their rest period by strange pulsating lights coming from the outermost moon of Mars, Demos. Although the crew claimed it looked like a sort of code, NASA claimed the lights were some form of natural phenomona (maybe swamp gas). The lights stopped after about 3 hours and the crew prepared to leave their parking orbit and land on the planet Mars. When the crew landed near the Nodus Gordii crater complex they were met with what they could only describe as "mental confusion." As one crew member described it: "As soon as we touched down it was like opening a door to hell. My mind was going in circles. I had trained for years for this mission. I had my list of objectives and sequence of events firmly planted in my mind but as soon as we hit the planet, all I could think of was how fast I could get out of here."

Well, we all know how the mission ended. After 3 hours on the surface of Mars the crew took off and returned to earth. The official NASA explanation was that "due to the great strain of many weeks in space in a weightless condition the crew suffered mental breakdown when they approached Mars."

Anyway, back to OSCAR. Since none of the previous unmanned missions to Mars had met with any difficulty, other than camera failure on most missions, it was decided to incorporate as much scientific equipment into the OSCAR capsule as possible.

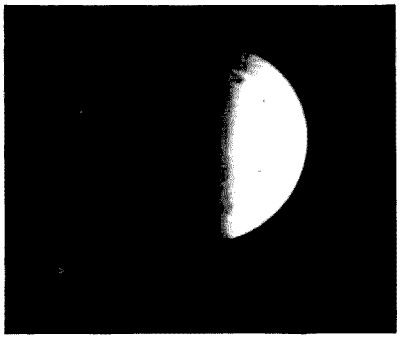

Photo 1

Photo 2

Photo 3

Through extraordinary cooperation and many sleepless nights in the building of OSCAR Mariner 1, he was ready for a checkout one week ahead of schedule. The entire package was installed aboard a twin engine Comanche aircraft and flown around the southern California area. OSCAR worked well, relaying pictures of the ground below while sending out the 450 beacon and repeating 1250 MHz to two meters and sending out telemetry data on environmental conditionn (we did not include a smog detector for southern California). The only problem with OSCAR turned out to be minor. The 450 MHz beacon was shifting in frequency and the power was down. The problem with the beacon was so minor that it was repaired while in the aircraft. OSCAR Mariner 1 was ready to meet Mars.

After several days of frustrating "holds" at the Cape, a Thor Monarch combination blasted OSCAR toward space.

After several months in space OSCAR was approaching Mars. While inside the main rocket, OSCAR was controlled through NASA. All commands and telemetry were received and relayed through the big NASA "dishes" around the world. Three hundred thousand miles from Mars OSCAR was given the command to turn on the camera and telemetry transmitter. Back came a strong signal indicating OSCAR was well and that pictures were being taken of Mars. It would be 15 minutes before we would see the first pictures from OSCAR since the slow scan television camera records the pictures on tape and then sends each complete set at once. The 15 minutes dragged on until finally the 1250 carrier appeared indicating a picture was about to be sent. However, all we heard was the carrier – no pictures. A command was sent to OSCAR to send back a status report. Evidently the on-board computer had become confused and erased the pictures before they were sent. Normally, after each picture series is sent back, the ground crew sends a command to OSCAR which in effect says, "We received the last set of pictures. Now erase your tape and start recording a new set of pictures." Anyway, the computer was confused and got the sequence out of order.

A new command was sent to take a new series of pictures and not erase the damn things this time. After another agonizing 15 minutes passed, the big screen at NASA came to life and the first picture from OSCAR started to take form. Slowly the picture took form as the tape played back the picture frame by frame. What started as a couple of white lines across the top of the screen turned into a large white ball – the planet Mars. After computer enhancement picture one shows the planet Mars from a distance of 300,000 miles. A great first for amateur radio operators around the world. The picture shows Mars during one of the planet's dust storms. During these storms wind velocity exceeds *500 mph*.

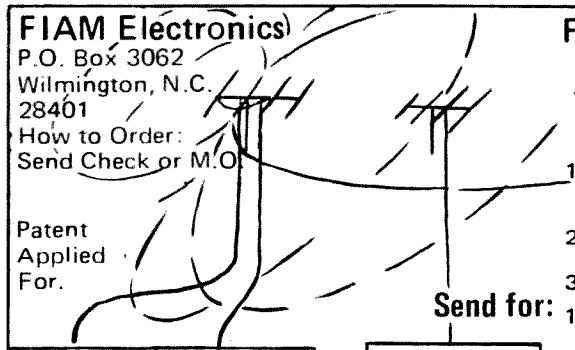
As OSCAR approached the red planet and went into a parking orbit more pictures were taken. Picture 2 is rather spectacular. The dark spot in the lower right hand corner of the picture is the innermost moon of Mars, Phobos, as it crossed the planet's surface. Several pictures were taken of Phobos. Picture 3 shows it to be a very old and rugged moon. In the upper corner of the picture you can see where part of the moon has been torn away – probably due to an impact with a large meteor.

As OSCAR left the parking orbit for a ride down to the surface of Mars, the cameras were rolling. In a series of pictures during the approach (pictures 4, 5, 6, and 7) one can see the polar ice caps of Mars and many of the larger Martian craters. Picture 8 shows the landing spot of OSCAR. This picture taken a few minutes before touch down shows the Nodus Gordii crater complex and an "X" marks the actual point of touch down.

Photo 8

After impact OSCAR was commanded to extend his antennas and all equipment, which he did beautifully. Now instead of having to be relayed through NASA, OSCAR's signals were coming directly from Mars to Earth. The first signals were very strong – in fact somewhat better than those relayed through NASA. Immediately OSCAR began transmitting the 450 MHz beacon, repeating 1250 MHz to 144.1, and scanning the planet for signals in the 500 kHz to 10 MHz range and retransmitting them back to Earth. Signals from the 1250 to 144.1 repeater were strong and steady. Hundreds of Earthside amateurs were communicating via a repeater on Mars. The activity was so immense that Wayne Green W2NSD/1 immediately suggested we split the channels into 600 kHz segments. The repeater is broad band allowing twenty-five to thirty conversations at one time.

At this time, no other pictures have been received from OSCAR. Somehow the computer on board is pulling its old trick of erasing the pictures before they are sent. The repeater is going well, as is the LSVL system. All systems have a life expectancy of at least one year. The LSVL system reports back that Mars is much friendlier than we at first thought.



OSCAR tells us that the atmosphere of Mars can possibly support life as we know it . . .

FREQUENCY MARKING of MOBILE ANTENNAS

Dave Ingram K4TWJ
Eastwood Village 50
North Birmingham AL 35210

I operate mobile a good bit, and I like the ability to move from one end of the band to the other. Also, when I move the rig between my two cars I take the Hustler resonators with me.

All this calls for retuning the resonators for a low swr, which is time consuming.

Although Newtronics supplies their resonator tip rods with a "split pea" type of marker (which you move to mark your favorite frequency) this is good for one setting only. What if you want to mark the whole band, every 100 kHz, or for two cars (which never seems to fall at the same setting of the resonators)?

My solution was simple . . . after finding the point of resonance, I filed a small notch into the tip rod, with the edge of a file. A slight notch on one side of the rod is easily spotted, and in no way hampers operation of the resonator.

My 40 meter resonator, which has notches for car No. 1, car No. 2, CW, mid-band, and phone portions, somewhat resembles Jesse James' gun handle, but I can move from car to car, or from phone to CW without worrying about swr, and know my signal is at its best.

A word of caution – keep a list in the glove compartment of which notches are for what frequency, lest you have to get out the trusty swr bridge and go over it again.

This system, while used on my "Hustlers," would work just as well on any of similar antennas.

INTEGRATED CIRCUIT TV SYNC GENERATOR

Claude Wiatrowski K9AAC/7
3401 N. Columbus Blvd.
Unit 7
Tucson AZ 85716

The prices of both digital and linear integrated circuits have fallen so quickly in the past few years that it now costs more to build certain electronic systems from discrete components than to buy the equivalent integrated circuit. This article describes just such a case: the use of digital integrated circuits in a synchronizing generator for an amateur television station. This is not the usual sync generator probably found in the majority of amateur television stations. It generates the same sort of synchronizing, blanking, and drive signals that commercial television stations generate. Equivalent sync generators using vacuum tubes are found in commercial stations to this day. They are notoriously unstable, difficult to adjust, consume upwards of 450 watts of power, and may fill one or two large relay racks. The integrated circuit version described in this article is extremely stable, has only five easily set independent adjustments, consumes a little over one watt of power, and will fit behind a standard rack panel. More remarkable is the fact that the total cost of the unit is under fifty dollars.

Now, if you are interested in contructing a sync generator, I will assume that you have

some experience in television systems. For those of you interested in the theory of the unit, I will also assume you have a familiarity with basic digital circuits and logic.

The blanking signal generated by this unit is identical to the signal all television stations, both amateur and commercial, use for this purpose. The sync signal generated, used by all commercial stations and very few amateur stations, may not be familiar to the amateur television operator so a short explanation is in order.

The Synchronizing Signal

Many simple camera designs that have been published in amateur journals rely on the blanking signal to synchronize the scanning oscillation in the receiving television. A more sophisticated approach is to add separate sync pulses on top of the blanking pulses while establishing a definite time relationship between the line and field frequencies, a truly interlaced system, as opposed to random interlace. Note, however, that in both systems the horizontal scanning oscillator of the receiving television will not be synchronized during the vertical sync pulse.

In order to achieve accurate interlace, it is imperative that the horizontal oscillator remain synchronized at all times. To accomplish this, the vertical sync pulse is serrated at twice the horizontal rate. The sync separator in a television receiver consists of a differentiator and an integrator. The output of the differentiator is a series of very short pulses corresponding to the edges of the synchronizing pulses. Since the widths of the pulses have no effect on the differentiator output, its output remains the same through the vertical sync interval due to the extra edges on the serrated vertical. It is this output that keeps the horizontal scanning oscillator synchronized at all times.

The integrator, on the other hand, responds to the widths of the pulses. The output of the integrator is roughly the average over an interval of time of the area of the pulse train. Indeed, then the output of the integrator increases as the pulses become wider and decreases as the pulses become narrower.

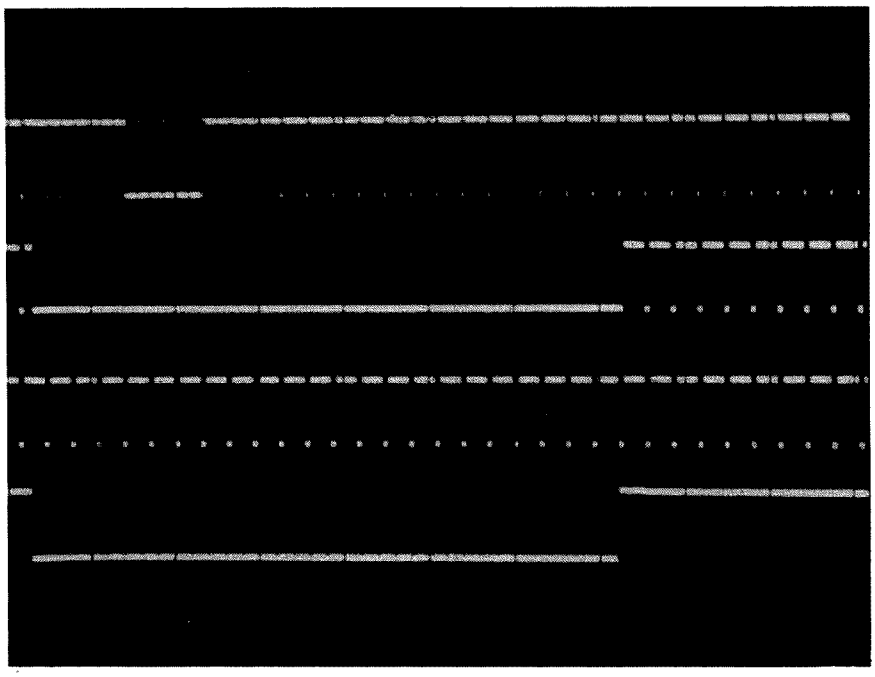

Fig. 1. Scope trace photo of sync and blanking signals and horizontal and vertical drive.

Since the vertical sync pulses are wide compared to the horizontal pulses, the output of the integrator corresponds to the vertical sync pulse interval. It is this output that synchronizes the vertical scanning oscillator.

Because every other field ends on a half line, the last horizontal sync pulse will vary

in position relative to the vertical pulse by 31.75 μs. This will cause the output of the integrator to be shifted by a small amount on alternate fields. This shift is enough to cause the lines on alternate fields to pair rather than be spaced equally. The group of pulses that remedy this situation are called equalizing pulses.

Six pulses, each of half the area and twice the repetition rate of the horizontal pulses, are placed before and after the vertical sync pulses. Being the same on every field, they serve to buffer the integrator output against shifts of the horizontal sync pulses which now occur farther away in time.

The complete sync, blanking, and drive signals are shown in **Fig. 1**. This has not been intended as a rigorous treatment of the television synchronizing system. For the interested reader, the subject is covered in many texts.

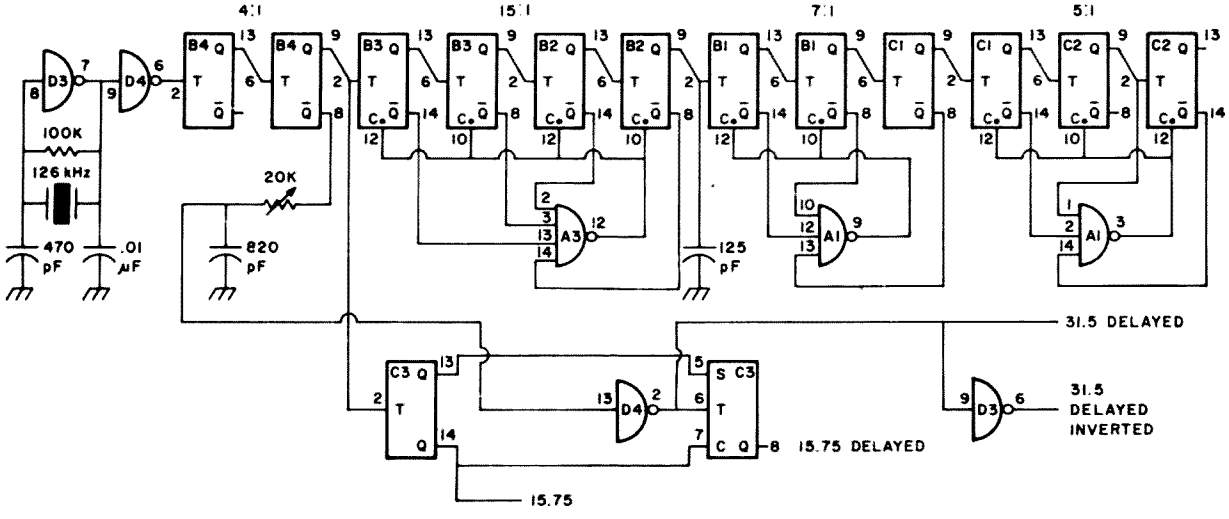
All gates are negative logic *nand* or positive logic *nor*. As this unit was designed with negative logic in mind, the analysis proceeds most easily from this viewpoint.

The flip-flops toggle on the negative-going edge of a trigger (T) pulse provided the set (S) and clear (C) terminals are left floating or are grounded. A signal of +3V on the set and 0V on the clear will cause the flip-flop to set on a negative-going trigger edge. (Set is interpreted as meaning terminal Q in the drawings will go to +3V and terminal $\overline{Q}$ will go the 0V.) An analogous situation exists for the clear input and the reset condition of the flip-flop. These flip-flops also have a dc clear which resets the flip-flop on a 3V pulse or level which overrides the inputs on all other terminals.

The Clock and Frequency Dividers

Basic components of any accurately interlaced scanning system are frequency dividers. One frequency divider divides the input frequency of 31.5 kHz by 525 to obtain a signal at the field rate of 60 Hz. Another unit divides by two to obtain 15.75 kHz, the line rate. In the sync generator described in this article, the dividers are actually electronic binary counters requiring no adjustments. The simplest of all these circuits will divide only by powers of two. An example is the 4:1 counter of Fig. 2 used to obtain a 31.5 kHz signal from a 126 kHz oscillator. It is necessary to apply feedback to count by numbers other than a power of two. The 15:1, 7:1, and 5:1 counters that make up the 525:1 divider in Fig. 2 are examples of this type of counter. Briefly stated, the output of the *nand* gate associated with each counter resets the entire counter to zero when the required count is reached.

The 7:1 counter has some minor variations. The last stage is reset by the action of the previous stage resetting. A capacitor is placed across the input of this counter.



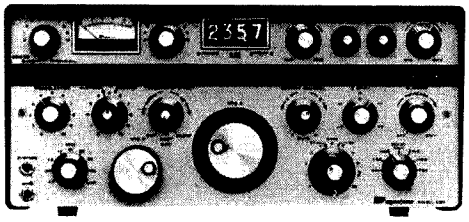


Fig. 2. Master oscillator frequency dividers.

the Incomparable CX7A

by signal/one

Quite frankly there is nothing with which to compare the CX7A. What else is there that has all modes 10 thru 160 meters with instant, no tuning band changing? With true break-in CW, a Pre I.F. noise blanker, R.F. clipping, and a built-in Keyer? With a separate receiver, wattmeter SWR meter, FSK shift, transmit offset and a freq meter digital counter?

RELIABILITY IS NOW standard equipment. Every component is instrument grade, hand-picked, and individually tested. The CX7A is American-made, "Ham" tested and 'burnt-in" by Hams who build, service, and sell it.

These two modifications are necessary to prevent extraneous pulses from resetting or triggering the counter stages. This is fast logic and the offending pulses are less than 1V in magnitude and 50 ns in length.

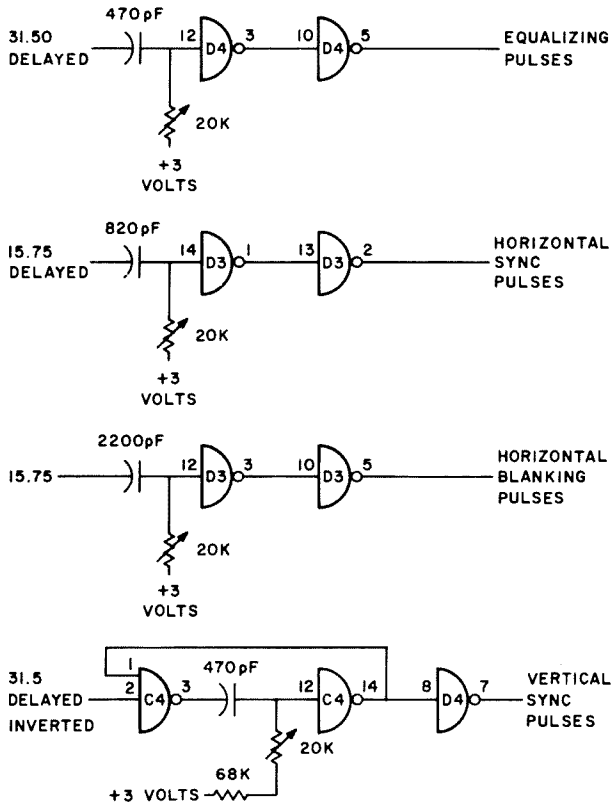

Fig. 3. Pulse generation.

There are two separate 2:1 counters. One counter is triggered by a signal delayed by an inverter and RC circuit connected to its input. The connections from the outputs of the nondelayed counter to the set and clear inputs of the delayed counter keep the two counters in phase. Without these connections it would be possible for the sync pulses to appear between rather than on top of the blanking pulses The delayed outputs are used to trigger all basic pulses except the horizontal blanking pulses. This delay which is adjusted to 1.27 μs accounts for the space between the leading edge of the blanking pulse and the leading edge of the sync pulse (sometimes called the front porch).

The delay is accomplished as follows. Assume that the input of inverter D4 is initially at 0V and its output is at 3V. If the input voltage to the potentiometer suddenly rises to 3V, the capacitor will only slowly

change to 3V. The rate of change is adjusted by the potentiometer so the input to the inverter rises to the point necessary to saturate the transistor in the inverter after 1.27 μs. Thus, 1.27 μs after the input transition takes place, the output transition will take place from 3V to 0V.

The master oscillator operates at 126 kHz. This frequency was chosen because crystals for this frequency are less expensive and more easily obtained than lower frequency crystals. The circuit is a Pierce oscillator constructed from a digital inverter. A second inverter is used to shape the output to trigger the 4:1 divider to 31:5 kHz. The 0.01 μF phase-shifting capacitor may have to be increased for a lower Q crystal. It is also possible for this circuit to oscillate at a harmonic of 126 kHz. The cure here also is to increase the value of the capacitor.

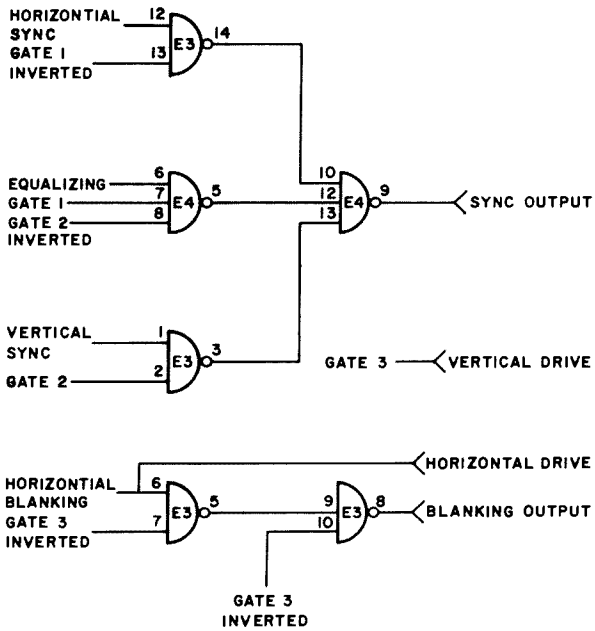

Fig. 5. Output gating.

Pulse Generation

Four monostable multivibrators are used to generate the following pulses: equalizing pulses, 2.54 μs; horizontal sync pulses, 5.08 μs; horizontal blanking pulses, 10.16 μs; and vertical sync pulses, 27.31 μs.

The 27.31 μs monostable is a standard design contructed from two gates. The other monostables are constructed from one inverter each. They are not true monostables in the sense that they do not have feedback.

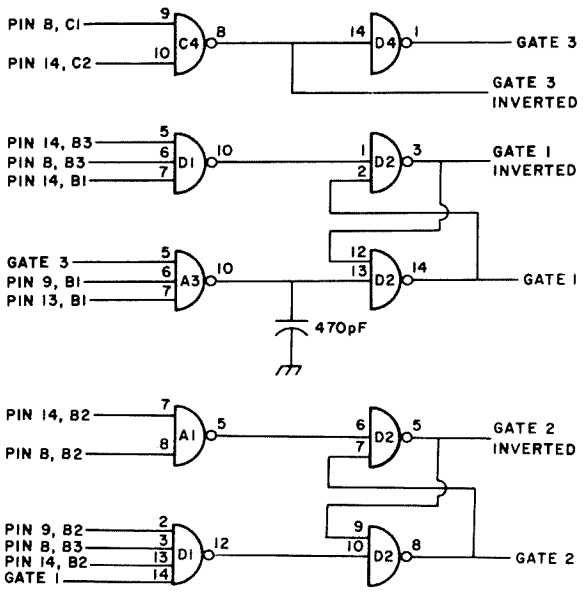

Fig. 4. Gate generation.

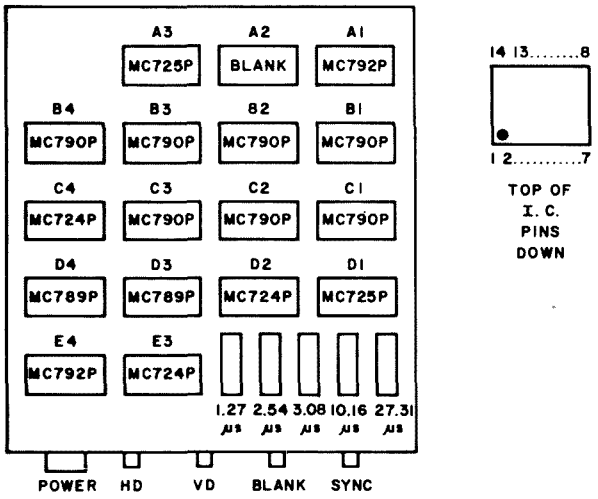
They will work in this application because the half period of the driving waveform is longer than the resquired pulse width. The circuitry is shown in Fig. 3. All outputs are inverted.

Generating the Gating Signals

The main counter has 525 unique states of each of its flip-flops. These states can be decoded to provide gating signals.

Gate 3 is the vertical blanking signal. It is generated directly as a combination of the states of two flip-flops of the counter. This gate is about 3 horizontal lines longer than the recommended width. This is virtually unnoticeable and the additional logic necessary to correct it hardly seems worth the additional complication and expense.

Gate 1 gates off the horizontal sync pulses and gates on the equalizing pulses. Gate 2 gates off the equalizing pulses and gates on the vertical sync pulses. Gates 1 and 2 are both produced by gating pulses from the main counter at the beginning and end of the gate times and using these pulses to set and clear flip-flops made of two cross connected *nand* gates. The circuitry is shown in Fig. 4.



Output Gating

Gates 1, 2, and 3 are used to turn off and on the basic pulses at the required times.

Gate 3 (Fig. 5) gates off the horizontal blanking pulses during the vertical blanking interval and it itself is inserted as the vertical blanking signal.

Possible Changes

It is possible to generate "on" and "off" pulses and use these to set and clear a flip-flop to generate gate 3 analogous to the circuits for generating gates 1 and 2. In amateur service this additional circuitry hardly seems worth the additional cost and complication. If the unit is intended for commercial service, this modification will be necessary. Other modifications that would normally be required for commercial service would be separate width and position flip-flops and associated gating for the vertical and horizontal drive signals. Another "must"

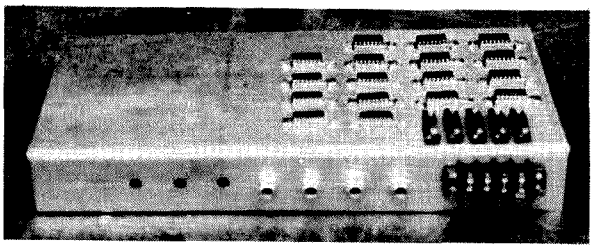


Fig. 6. The completed sync generator.

is the inclusion of alternative methods of master frequency control, such as a method to lock the generator to the power line or some external source (such as network or remote site sync generator).

Construction

The unit is constructed on a 6 x 12 in. chassis of which only 6 x 7 in. is used for the sync generator (Fig. 6). The primary consideration to bear in mind is ease of wiring. Each integrated circuit has a possible fourteen or more connections to it and space for wiring can be rapidly depleted. This unit could ideally be constructed on a single printed circuit card, although the layout of such a large printed circuit is not a simple task.

On all integrated circuit sockets, pin 4 is ground and pin 11 is connected to +3.6V. The crystal socket was mounted on a bracket on the underside of the chassis. All discrete components were mounted on a directly on the IC sockets. I do not recommend this procedure as it makes an already crowded situation worse. A possible improvement would be to mount all discrete components on a piece of Vector board mounted on the underside of the chassis.

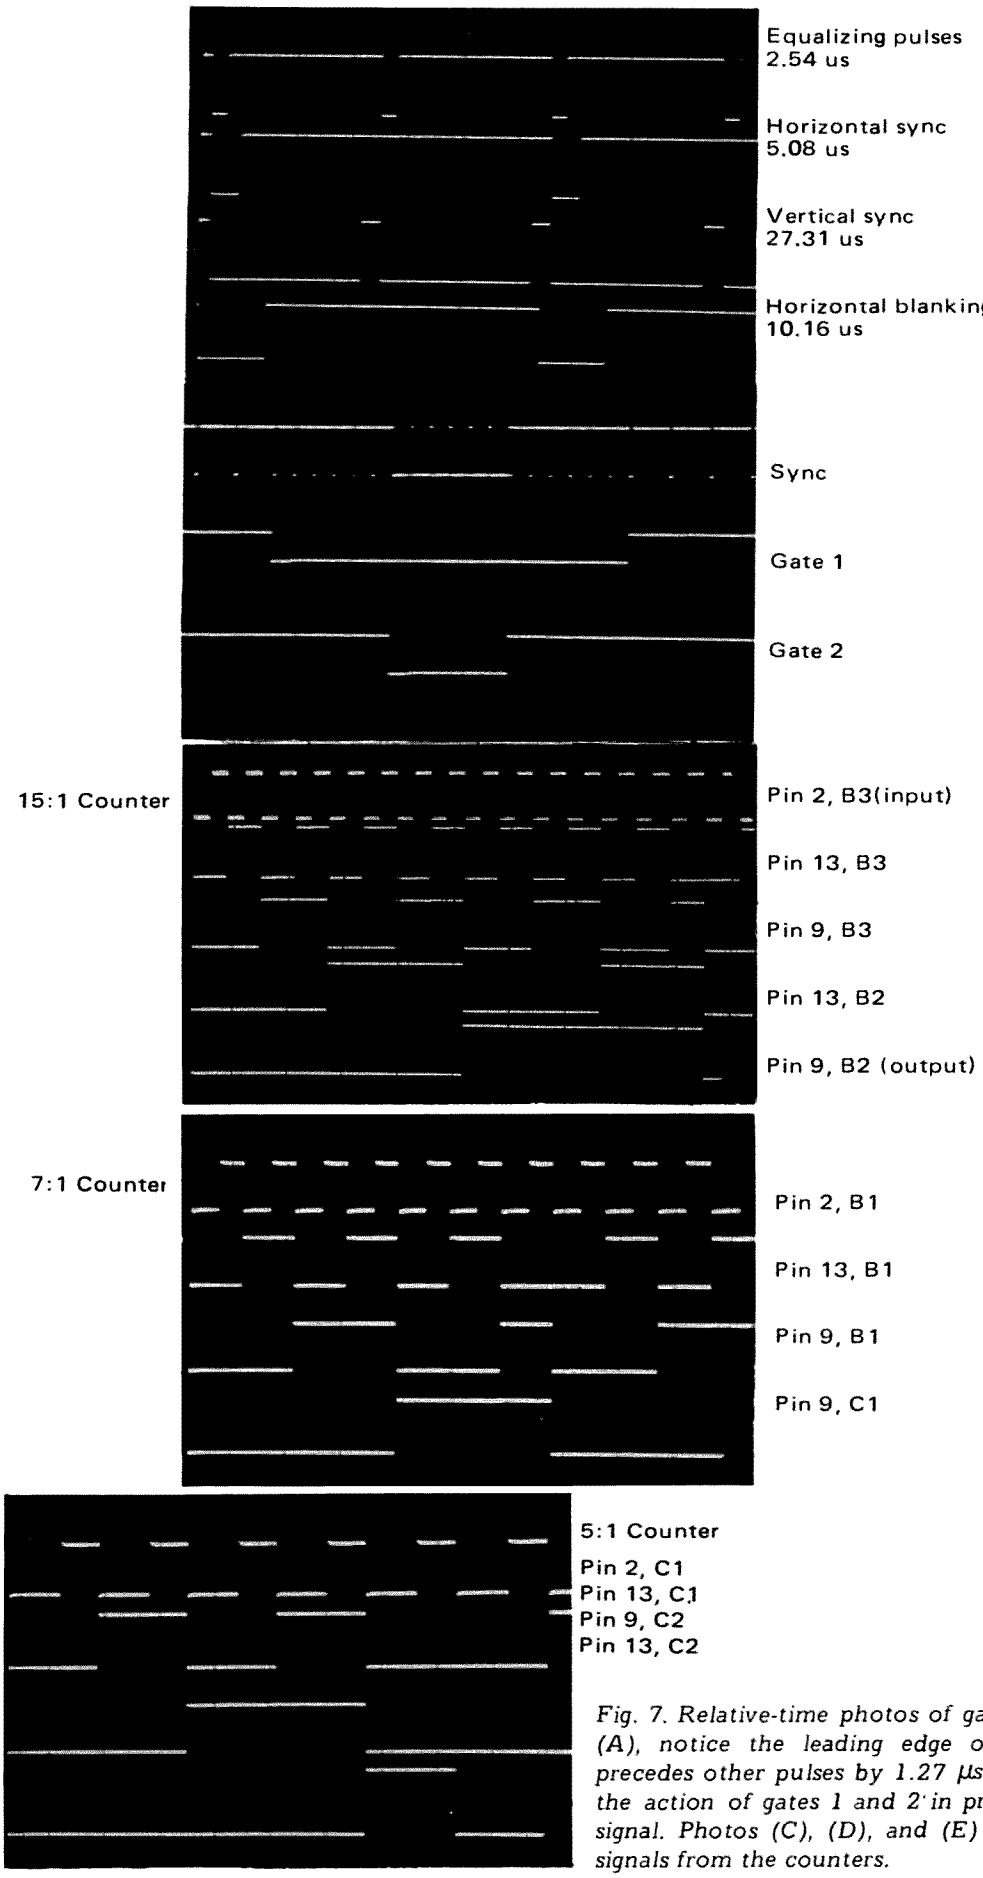
The multiturn potentiometers are a convenience but satisfactory operation should be possible with ordinary carbon potentiometers. Four phone sockets are used for sync, blanking, and vertical and horizontal drive connections.

The large empty space on the chassis, the extra output connectors, and the two spare terminals on the power block are for possible expansion to color. The IC socket is a 16-pin type that works as well for these 14-pin packages.

Adjustment Procedure

Assuming that you prefer to wire and test the generator in sections, the first section to be wired should be the clock and frequency dividers. Observe the input and output of the 15:1 divider on a dual-trace oscilloscope. There should be 15 input pulses for every output pulse. If you do not have dual-trace facilities, you can mix the two signals in a spare gate. Although the output does not look the same as with a dual-trace scope, the number of pulses that should occur *during the output pulse* for each counter can be determined from Fig. 7, which shows scope trace photos of the gating and counting circuits. The other dividers may be checked in the same way.

See that the 15.75 kHz and delayed 15.75 kHz signals are in phase. They will be if you have not made a wiring error. Adjust



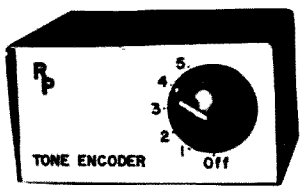


Fig. 7. Relative-time photos of gating functions. In (A), notice the leading edge of blanking pulse precedes other pulses by 1.27 μs. Photo (B) shows the action of gates 1 and 2 in producing the sync signal. Photos (C), (D), and (E) show the output signals from the counters.

the delay so that there is a 1.27 μs between the leading edges of the two signals. Again, without a dual-trace oscilloscope, mix the *inverted* nondelayed output with the normal delayed output. The pulse on the oscilloscope from the output of your mixing gate has a width equal to the delay time.

Since the outputs of this unit are the outputs of gates, they *will not* drive a low impedance load. All inputs to other equipment should be high impedance and the line should *not* be terminated with a resistor. This situation is ideal in my station as most equipment is of IC contruction and the output of the sync generator simply drives other gates. If you absolutely require low impedance signals, the outputs of the gates may be buffered with simple emitter followers.

Wire the monostables and their inverters next. Look at the output of the inverters and adjust the pulse widths to the correct values. Remember the pulses are negative going at the outputs of the inverters. Wire gate 3 first, then gate 1, and finally gate 2. The outputs of the three gates may be compared with the scope pictures in Fig. 7. Their widths should be: gate 1, 571.5 μs; gate 2, 190.5 μs; gate 3, 2857.5 μs. Lastly, wire the output gating and connect it all together. Sync, blanking, and drive should now appear at their respective output terminals. Check the appearance of the blanking and drive with an oscilloscope. The sync waveform may only be viewed reliably using an oscilloscope with delaying sweep. The delay has to be longer than two fields, as the horizontal sync pulses alternate their position every other field. Without these precautions you can not be certain that your scope trace is an accurate indication of the output waveform. Note, however, that *no* adjustments *have* to be made while looking at this waveform so if you trust your wiring and previous adjustment procedure, you can be confident of having a correct sync signal. If you still insist on seeing the sync waveform, it is possible to add a single flip-flop as a 2:1 counter connected to the output of this 2:1 divider to the external sync on your scope and you should be able, after some adjustment, to see the sync signal. . . . An Introduction to a Science

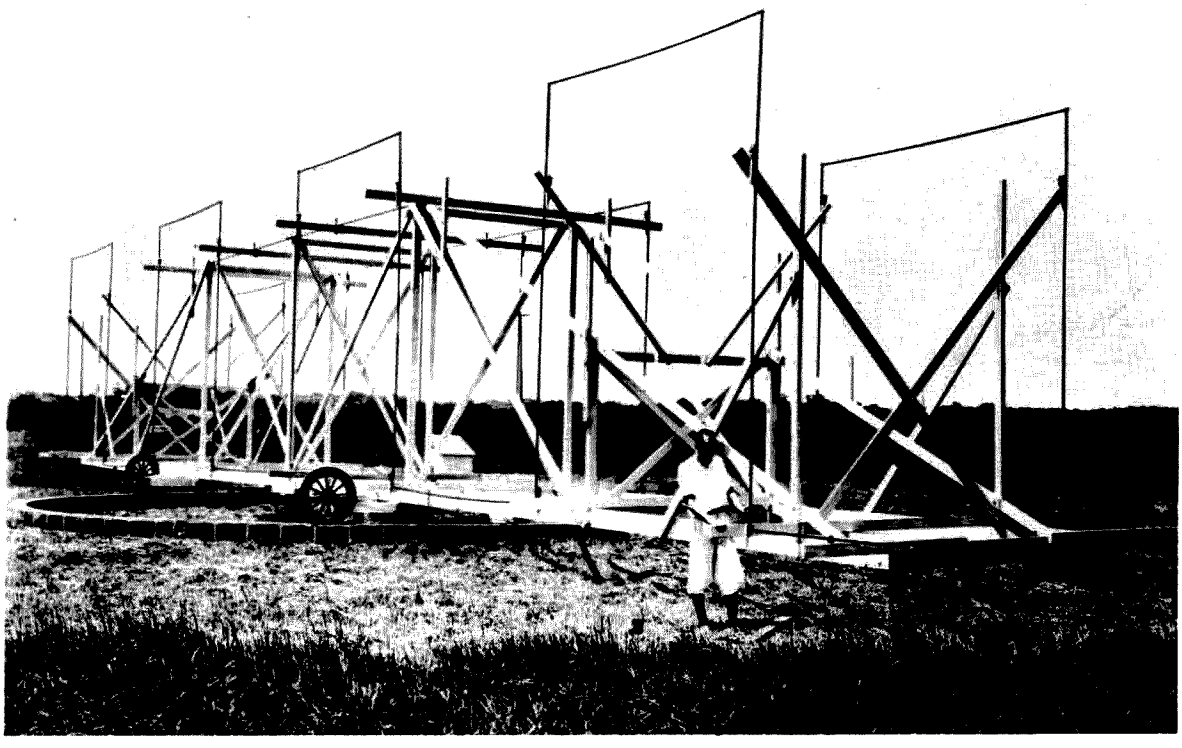
Radio Astronomy and Amateur Radio

Osler H. Johns, Jr. W4ZBE
114 Rollins St.
Orlando, Fla. 32804

For a quarter of a million years, since man first stood erect on his hind legs, he has gazed with wonderment into the mysterious universe using only his eyes to receive the tiny bits of light energy arriving from the distant parts of space.



In the last one hundredth of one percent of time, in the history of mankind, man has used devices to aid his visual observation of the universe. The refracting telescope by Galileo was the first.

Only in the last one thousandth of one percent of mankind's lifespan has man been aware of energy other than light arriving at his planet. In fact, serious concentrated work in these fields has been taking place for less than 25 years.

Karl Jansky. In 1931 Bell Telephone Labs assigned a young engineer named Karl Jansky to investigate the problems involved with transoceanic radio interference. Lightning discharges, aurora, and the unknown way in which radio waves skipped off of the ionosphere combined to make for serious problems in long-range radio communications.

In order to monitor interference noise the young engineer built a large steerable antenna with, for the time, a very sensitive receiver. The antenna was 100 ft long and could be rotated 360 degrees to act as a direction finder. A frequency of 20.5 MHz was selected – a frequency well above that commonly used for broadcasting and communications in 1931.

Jansky's experiments detected a noise of a strange nature. The noise was of a continuous type rather than the erratic type associated with most types of radio interference originating within the atmo-

A historic photo of the late Karl G. Jansky of Bell Telephone Laboratories with the rotating antenna he used to discover radio waves coming from space. Mr. Jansky's investigations during the 1930s into the causes of strange noise in telephone equipment resulted in the discovery of radiation noise from the center of the Milky Way and gave the world a new science – radio astronomy. (Bell Labs.)

sphere. The noise was relatively strong and displayed the interesting property of starting 4 minutes earlier each day.

Karl Jansky himself correctly theorized that the noise must be originating from extraterrestrial sources in the galaxy.

During the next two years the Bell Labs engineer continued to study this extraterrestrial hiss. It was discovered by Jansky that the signal level was highest in the direction of the center of our own galaxy. He published his findings in professional journals during the years 1932 to 1935.

After 1935 the Bell Telephone Labs transferred Jansky to another research project not connected with radio noise from space.

Grote Reber (W9GFZ). Jansky did not follow up on radio astronomy after making his initial discoveries. His interests lay principally with radio communications and not with astronomy.

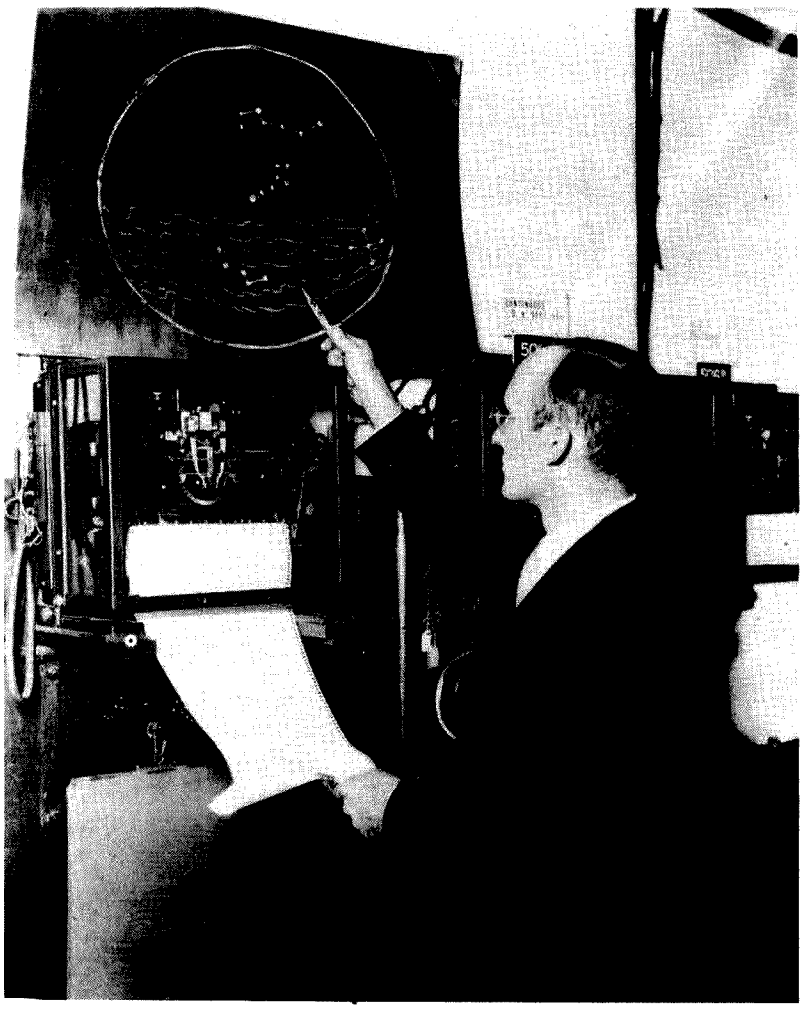
Grote Reber, a professional electrical engineer and avid amateur radio operator had read all of Karl Jansky's papers on extraterrestrial noise. As an amateur radio operator he had contacted other "hams" on all continents and in every state using equipment he built himself.

Reber, all on his own and in his own back yard, constructed a 31 ft parabolic dish antenna, and a receiver capable of receiving signals at 3300 MHz.

In 1937, this in itself was quite an amazing accomplishment. The frequency picked was twenty times higher than any frequency being used during the mid-1930s. It must be remembered that this was years before radar or microwave communications came into use. Dish antennas and microwave receivers were very rare indeed.

The equipment worked but no noise was received, so Reber decided to come down to a frequency of 910 MHz. Again no astronomical noise was received so Reber again decided to come down to a still lower frequency of 160 MHz.

By 1939 the diligent amateur had succeeded in receiving radio noise from several sources; however, astronomers of 1939–40 were reluctant to give complete support to



some of Reber's findings because radio wave radiation did not always correspond to optical astronomy findings.

In 1944 Reber published the first radio sky map; a map of excellent professional quality considering it was made by one enterprising amateur using all home built equipment.

An interesting method was used in making this radio sky map. Because of economy, Reber's telescope was not built to be steerable in azimuth but only in declination. For this reason Reber would position the antenna at one point of declination. The next night the antenna would be plunged a few more degrees. The next night the dish would be plunged several more degrees, and so on each night for the complete travel of the antenna in declination. Each night the sky would sweep past the antenna for each position of declination, thus after several nights the entire sky could be effectively mapped.

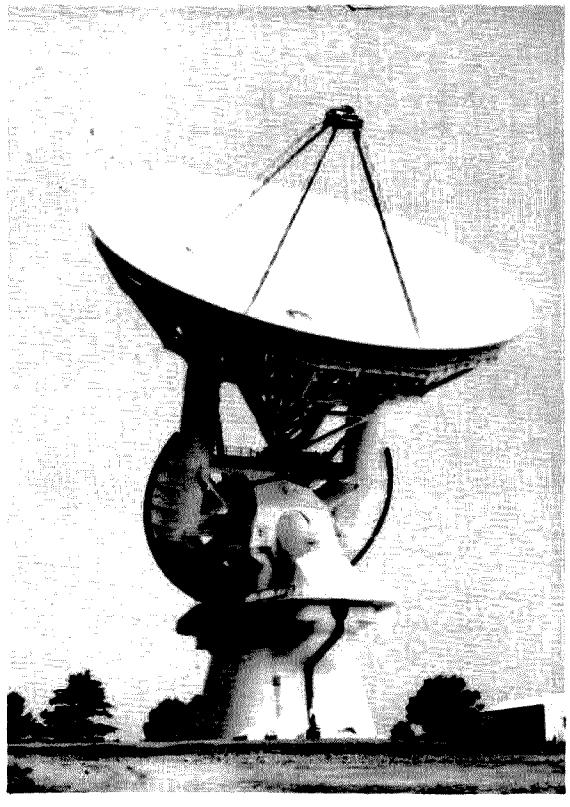
From the mid-1930s until after WWII there was only one radio astronomer – Grote Reber. Reber is still working as a scientist for the ESSA department of the U.S. Government; his major interest is with radio wave propagation.

World War II brought about many advances in the state of radio communications and radar. The most important advances were in highly sensitive high frequency and microwave receivers and in highly directional antennas. After the war, these advances in radio technology were put to use in the building of radio telescopes.

The late Karl Jansky of Bell Telephone Laboratories is shown pointing to the position on a chart where radio noises from space were first heard. While attempting to pinpoint the source of noise interfering with radiotelephone service, Jansky detected a peculiar hissing sound coming from the area of the Milky Way. Later this hissing was identified as radio signals generated by the natural processes in stars and galaxies. His work resulted in the new science of radio astronomy, in which the heavens are studied by listening to radio waves rather than looking through an optical telescope. (Bell Labs.)

One famous astronomer who decided to concentrate his efforts in the field of radio astronomy was an Englishman named Sir Bernard Lovell. Lovell is the director of the Jodrell Band Experimental Station. At Jodrell Band the first really large, fully

steerable radio telescope was assembled. The dish antenna was a monster of some 250 ft in diameter, but it could be aimed at almost any point in the sky with great precision! For some time the reflector was the largest radio telescope in the world.



NRAO. By the early 1950s it became obvious that if serious work was to be accomplished using radio telescopes very large and very expensive instruments would have to be built. Such undertakings would require federal financial support because of the enormous cost of the equipment.

By the middle 1950s scientists interested in radio astronomical research had requested the National Science Foundation to construct a national radio astronomy observatory.

Green Bank, West Virginia, was chosen because of its remote location far from man-made electrical interference; the mountains surrounding the location acted as a shield; and a large expanse of available well-suited land became the choice for the national radio observatory.

Grote Reber (W9GFZ) the world's only radio astronomer from the late 1930s until after World War II. During the 1930s Reber constructed, on his own, a highly sensitive receiver operating in the microwave and UHF regions and utilizing a 31 ft dish antenna. He both constructed and designed his equipment and interpreted its findings. Without question, this man will be considered one of the giants in amateur radio circles in years to come. (National Radio Astronomy Observatory.)

The largest equatorially mounted telescope in the world (optical or radio) is the 140 ft dish operated by the NRAO at Green Bank, West Virginia. A single bearing supports the entire 2500-ton structure. This bearing is polished to a tolerance of 3 mils and floated in a 5-mil layer of oil. Such precision allows the great instrument to be pointed at any direction of the sky with extreme accuracy. The receiver is normally used at wavelengths shorter than 2 cm, or 15,000 MHz. The telescope took seven years to design and build and cost $14 million. (National Radio Astronomy Observatory.)

The complex of telescopes erected in the West Virginia mountains near Green Bank makes it the world's most versatile radio observatory.

The instruments include a 300 ft telescope which is the world's largest movable telescope; a 140 ft telescope with a very precise reflecting surface; and three 85 ft telescopes used in conjunction with each other. This array allows the three telescopes to in effect act as one telescope 5000 ft long. A portable 42 ft telescope rounds out the collection of instruments. The portable telescope allows the astronomer to extend the base line of the three permanent 85 ft telescopes, thus making a telescope which in effect is even longer than 5000 ft.

The engineers and scientists at Green Bank are already at work on an even more ambitious project. This new telescope would actually be an array of many separate antennas spread over a 26-mile area and feeding a single receiver. This would in effect make for an antenna that would be 26 miles in diameter. This 26-mile telescope has been aptly called the VLA (for "very large array").

University of Florida. The astronomy and physics department of the University of Florida at Gainsville, Florida, for many years has been doing research on radio waves arriving from noise sources within the solar system. The frequency used for listening is far below the frequencies usually employed in radio astronomy work. As a matter of fact the frequency is very close to that used by Karl Jansky in his original work.

Jansky, however, never received radio radiation from individual planets. If he did receive noise from planets he was not aware of it because of the poor resolution of his antenna system.

Much original knowledge about planetary astronomy has come from the University of Florida; of particular interest has been the planet Jupiter's relatively strong radiation.

Professors Alex G. Smith and Thomas D. Carr of the University of Florida have been particularly active in high frequency planetary radio astronomy.

Arecibo. No history of radio astronomy would be complete without including the giant telescope at Arecibo, Puerto Rico.

This huge telescope was the brainchild of Professor William E. Gorden of Cornell University.

The dimensions are truly staggering: 1000 ft in diameter; 500 ft deep; and a 500-ton feedhorn that is 200 ft long.

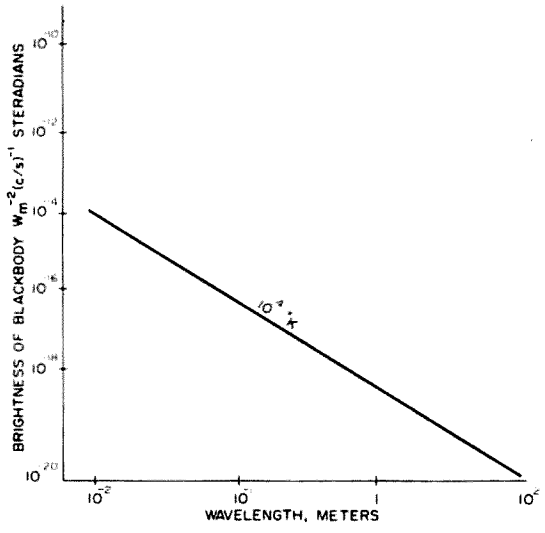

Fig. 2. Blackbody radiation, rf spectrum.

The large dish has been used for both active and passive radio astronomy (active radio astronomy being another name for radar astronomy).

As an active instrument it has allowed radar signals to be bounced off of the moon with great accuracy. Venus has also been a target for Arecibo's energy.

As a passive instrument it lays claim to being the world's largest telescope, optical or radio.

The $9 million project was built by Cornell University through funds made available by the Department of Defense's Advanced Research Projects Agency and the Air Force's Cambridge Research Labs.

Cornell University continued to operate the telescope after construction was completed.

Owens Valley Radio Observatory. The observatory which has located and identified more radio sources than any other observatory is the Owens Valley Radio Observatory of the California Institute of Technology at Big Pine, California.

Two 90 ft dish antennas make up the heart of the observatory. These are especially fine instruments built to close tolerances.

Financial support for the Caltech observatory was granted by the Office of Naval Research. The original construction cost amounted to $1,500,000. The telescopes were placed in operation in December 1958.

Australia. Much of the research in radio astronomy is presently going on in Australia.

B. Y. Mills is probably the most distinguished radio astronomer from the Island continent. He is the inventor of the "Mills Cross" which is an array of telescopes arranged for maximum gain. Mills is also responsible for most of the mapping of the sky in the southern hemisphere.

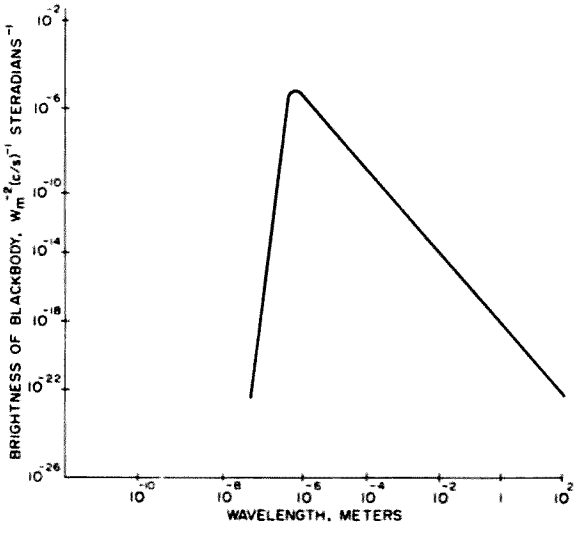

Fig. 3. Blackbody radiation curve for frequencies beyond rf portion of spectrum.

Radio Noise Sources

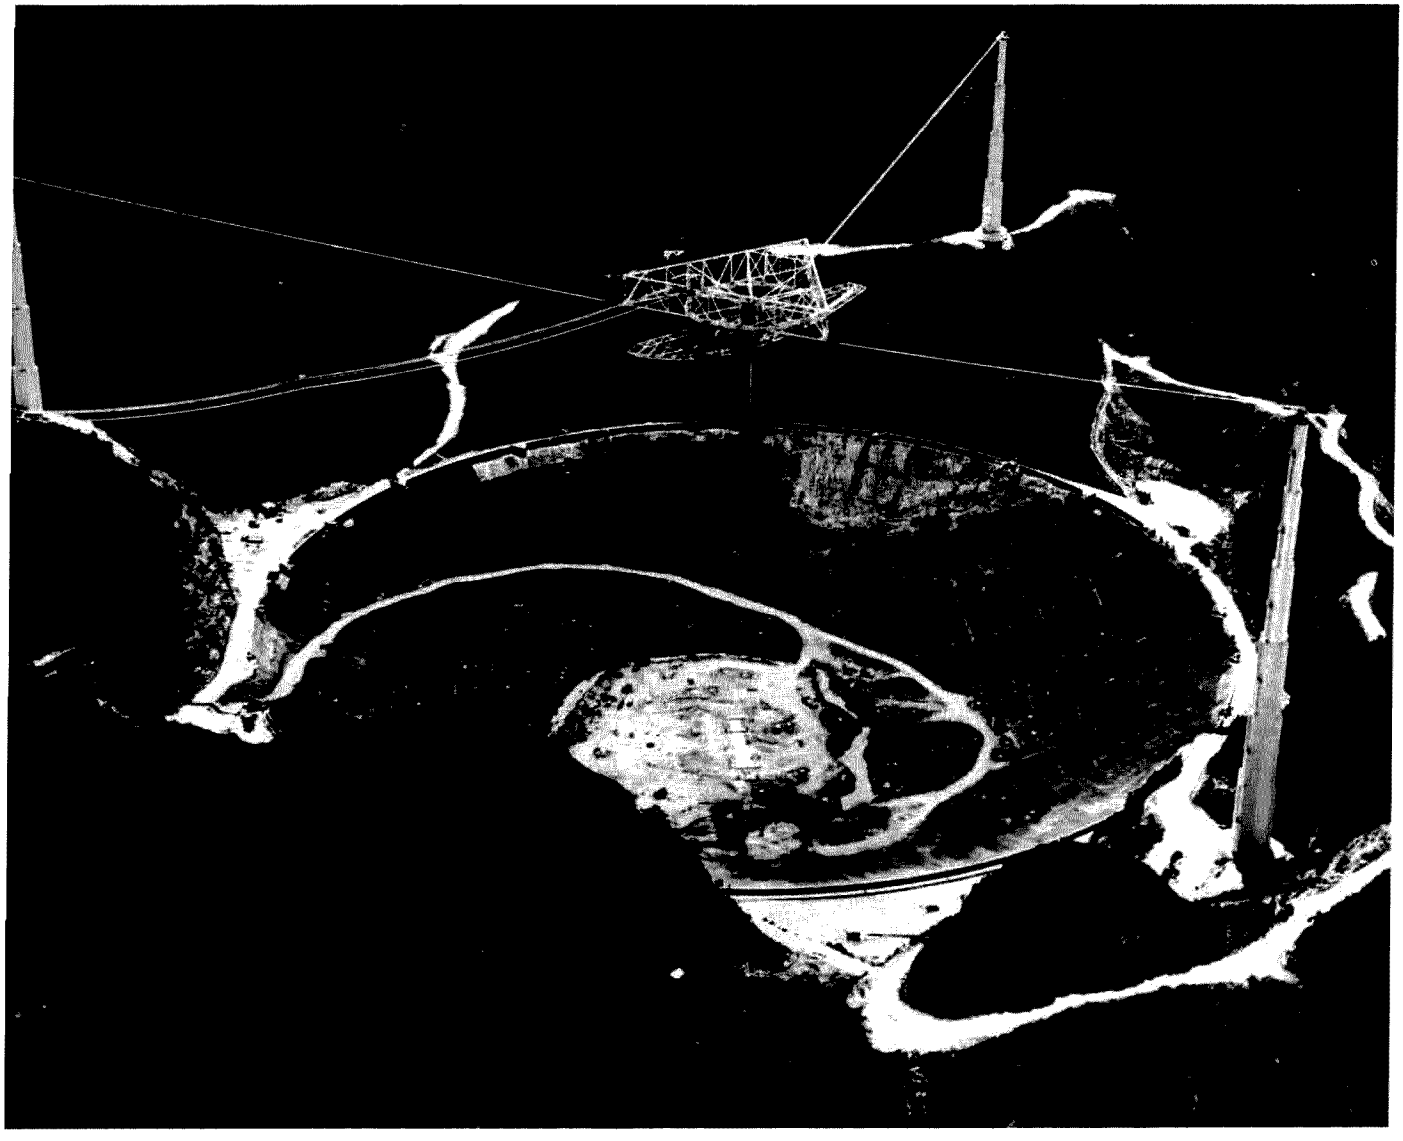
Radio waves make up a portion of what is known as the electromagnetic spectrum. The relative positions of the various forms of energy that make up the electromagnetic spectrum can be seen in Fig. 1.

The only difference between the various forms of energy is the wavelength and the energy they possess. In reality there is no sharp dividing line between the various forms but one form slowly takes on the identity of the next.

All objects above an absolute zero temperature radiate electromagnetic radiation into space with the energy being directly proportional to the frequency and inversely proportional to the wavelength. This is known as Planck's law and was formulated in 1901 by Albert Einstein.

A perfect radiator (and absorber) is called a blackbody source. A perfect black-

body is never found in nature, so the objects in space radiating electromagnetic energy fall somewhat short of the blackbody formula for brightness.



It should be obvious that brightness of a light wave is the same as signal level or intensity of a radio wave at a specific radio frequency.

When plotted on a logarithmic scale, the blackbody radiation looks something like the plots on Fig. 2. If the chart were extended past the radio frequency portion, the chart would look like that of Fig. 3.

Temperatures generated within the telescope itself often limit the ability to detect weak signals. The heat generated by transformers, vacuum tube filaments, sunlight heating the antenna, sunlight heating the transmission line, and heat from other electronic components must be taken into account.

The minimum temperature which the telescope will be able to detect can be found by a formula that involves such parameters as minimum detectable temperature, system noise temperature, rms system noise, antenna noise temperature, etc.

The above discussion has been concerned with what is known as thermal

The giant of all radio telescopes spans some 1000 ft in diameter and 500 ft from the feedhorn to the base. The feedhorn weighs 500 tons and measures 200 ft on each side. Arecibo has been used as both a radio telescope and a radar telescope. The 500-ton feedhorn is supported only by cables. Several contacts via EME with hams in the United States and around the world have been made on the ham bands with the big dish. (Cornell Univ., Arecibo Observatory, Puerto Rico.)

blackbody radiation; however, other methods of electromagnetic wave generation are known:

Thermal emission from ionized gas: As an ionized gas the electrons are free from the nucleus and thus are in no specific energy level; however, the electrons are accelerated as they come in the vicinity of other charged particles. These accelerations of electrons cause electromagnetic radiations.

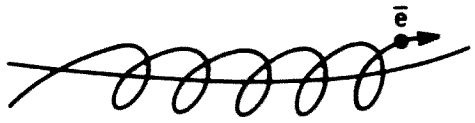

Fig. 4. Synchrotron emission: Free electrons in the arms of a galaxy moving at high speed in a gravity field.

Synchrotron radiation: The first emission which is nonthermal in nature is the synchrotron radiation (Fig. 4). In fact most nonthermal radiation in the universe is produced by this method.

Synchrotron radiation occurs whenever high velocity (high energy) electrons are accelerated to near the speed of light by a powerful magnetic field. The energy released by synchrotron mechanism is more intense than that released by thermal emission from ionized gas. As a consequence, this type of radiation is responsible for some of the most powerful sources yet detected.

Spectral lines: As electrons jump from lower to higher or from higher to lower energy levels within the atom, energy is either radiated or absorbed. This energy shows up as spectral lines throughout the electromagnetic spectrum.

Many of the spectral lines fall within the visual portion of the spectrum; however, some elements such as hydrogen are capable of producing spectral lines a considerable distance from visible light.

The most famous spectral line within the radio spectrum is the 1420.3 MHz hydrogen line. This is the spectral line produced by neutral hydrogen.

Evidence of this line is found throughout the universe; it occurs in open space between stars and between galaxies and at various temperature levels.

The above is only a brief survey of the mechanics of electromagnetic wave generation simplified from the book *Radio Astronomy* by John D. Kraus. Every serious student of the subject should consult Dr. Kraus' book for a more detailed discussion.

This portion of the text of this two-part article series has served to acquaint you with some of the individuals who pioneered radio astronomy as well as some of the technical disciplines involved in the field. Part II of the series will cover details about the radio spectrum of interest and describe basic radio telescope systems.

WHAT'S PAST IS PROLOGUE

Delivered by
A. Prose Walker
Chief, Amateur and Citizens Division
Federal Communications Commission

There are more VIPs here tonight than at a National Convention . . . W3RE.

Introduction by Nelson M. Griggs W3UCT

Photos by Paul Segal

Photo of Mr. Walker courtesy of Auto-Call.

Gaithersburg, Md., Mar. 11 – A. Prose Walker, W4BW, the new Chief, Amateur and Citizens Radio Division of the FCC, proposed tonight that a "professional" amateur satellite be launched in synchronous orbit, possibly at the direction of the President of the United States. Walker was the featured speaker at the 16th annual dinner of the Washington Chapter, QCWA, meeting at the Washingtonian Country Club. He further suggested that the new bird fly in 1976 in celebration of our nation's second centennial.

The glittering audience of 376 paying guests included, in addition to QCWA chapter and national officials, the Board of Directors, the Executive Committee, the Secretary and General Manager and other staff members of the ARRL.

Walker was introduced by Harry Dannals W2TUK, newly elected League president, following the presentation of Golden Anniversary awards to four local chapter QCWA members: Charles Lewis, W3AXW; Elizabeth Zandonini, W3CDQ; Charles Stay, W4HE; and Edward Clammer, W3UN. Dannals also took the opportunity to present ARRL life memberships to those eligible applicants (including Walker) who happened to be present.

Prior to the main event speculation had been rife as to what the new chief might say that had not been already widely publicized. In this, the fifth in a series of talks given before amateur groups around the country, Walker chose the questionable future as his subject.

The text of Mr. Walker's speech follows:

The selection of a subject for tonight was somewhat difficult. There were three categories which seemed to fit the occasion. First I thought of talking about "The Good Old Days," but there are many of you here who know much more than I about that era . . . who can better recall the virtues of spark, the pungent smell of ozone, the blinking of the "Slop Jar" rectifiers, MHz-wide amateur bands without much QRM. So I gave up on that one.

The next possibility seemed to be "The Troublesome Present." That is a subject that I probably know something about. But I have *been* talking about such matters recently, at Las Vegas, Dallas and Miami, and most of you know what I think about many subjects which concern amateurs today. Furthermore, your speaker on this occasion last year, Mr. Burch, talked about one of the most troublesome aspects of current problems, the interpretation of section 97.39 of the Rules, commonly known as the "eye bank docket." But neither that subject nor a lot of others are yet resolved. Probably it seems to you that it will take some kind of a miracle to conclude most of the pending matters. Well, I think that miracle has happened, for we now have John Johnston with us in our division, as chief of the rules and legal branch, responsible for the resolution of pending matters.

So rather than try to further elucidate any of those, I decided to discuss the only subject left, "The Questionable Future."

According to an old Chinese proverb, *"It is extremely difficult to prophesy, especially with respect to the future."*

But there are signs and events, if properly interpreted, which may give us the jump on the natural evolution of things in amateur radio, or perhaps even guide them to a more proper conclusion. At least it might provide the opportunity for a head start. Whether we take advantage of it is up to us.

In respect to the "questionable future" turn your minds, if you will, to the potential of satellite communication for amateur radio, as has already been demonstrated commercially. I know that you thrilled a couple of weeks ago to the sight and sound of our President and the events surrounding his trip to China. Last summer in Geneva, the ITU established the Amateur Satellite Service . . . A.S.S. . . . one of our well known pundits who is often in error but never in doubt, says that if we sit on it we are sure to lose it . . . which is generally the history of spectrum allocations . . . as it should be.

Recently, I had the opportunity of hearing some ideas on a *"professional"* amateur satellite from Bill Eitel, W6UH, well known to all of you as one of the founders of EIMAC, and a leader in the communications industry. We didn't have much time to work out the details, but Bill's idea stimulated some additional thinking about the kind of satellite he perhaps had in mind. During the next few minutes, let's think about that satellite . . . what it might be . . . what it could do . . . the limitations that probably will be imposed on it . . . and the best way to use it, not only for amateurs but for the benefit of mankind.

I say mankind, because we shall think about something that could be beyond the normal concept of the 'public interest, convenience and necessity."

All of the five OSCARs launched to date have been short-lived, low-altitude, non-synchronous orbiting satellites. Those that did contain repeaters /transponders or whatever you wish to call them, were available to only a small number of amateurs throughout the world . . . amateurs who had unusual competence to track the satellites and top-notch equipment for receiving and transmitting. The people who were instrumental in building and launching them deserve a tremendous

amount of credit for their pioneering achievements. Without their work, it is most unlikely that the ITU would have established the Amateur Satellite Service . . . it wasn't easy even with their achievements . . . and we didn't get everything we wanted, but at least we got our foot one inch further in the door. Let's speculate briefly about the major technical characteristics of one version of this "professional" amateur satellite (with apologies to Bill Eitel if this isn't quite what he had in mind).

One of the major objectives is that it be available over a long period of time: Not just a month or 6 weeks, but a period of several years.

Predicted life of satellites today is in the order of five years. Whether we could obtain that is debatable perhaps, but it should be operable for at least a couple of years. This requirement is synonymous with a solar cell power supply, backed up by batteries.

Secondly, for the satellite to be generally available, its orbit must be such that complicated orbit prediction is not required nor complex tracking equipment necessary. Third, and this is almost a part of Point 2, availability to all amateurs of the world at one time or another, points to a near-geostationary satellite; one which slowly drifts around the world remaining available for periods of weeks or even months to amateurs in any particular hemisphere. This is the kind of satellite I would like to discuss . . . not a toy, but a "professional" amateur communication satellite, the limitations of which are only those imposed by cost considerations and the decision to put it into orbit.

Perhaps you are skeptical at this point. Instead of thinking about it in terms of resources, turn your thoughts around 180°. For centuries it has been true that the availability of the resource produced the decision to accomplish the objective. Within the past decade that has changed, and now it is *the decision to accomplish the task which brings about the resource* necessary for the job. Throughout the relatively short period of our engagement in space exploration, the decision was first made to do the job . . . then we set about providing the resource which resulted in the technology and hardware to probe the outer limits of the earth's atmosphere and beyond. This list of man's accomplishments in space is long; Explorer, Vanguard, Topside Sounders, Earth Resources Satellites, Orbiting Astronomical Observatory, Solar Observatory, Geodetic Observatory, Weather Satellites, not overlooking the series of manned flights starting with Mercury, Gemini, Apollo, and now Skylab and Shuttle.

Without denying the "fall-out" benefits from this gigantic effort, none of these endeavors have really been for the direct benefit of the common man. This may well be the shining opportunity to bring the benefits of satellite technology down to at least a segment of the population of the world through a "professional" amateur satellite. If the decision to put this kind of satellite in orbit were made by the Director of the OTP or the President of the United States, how many of you doubt that it would go up? Why not have it ready for the Bicentennial celebration of our country in 1976? I hope and believe that this will come about, somehow, somewhere, in some way. I know that Bill Eitel is thinking seriously about the prospects. The technology is here . . . are the amateurs ready?

What kind of satellite is this? It must be reasonably small and lightweight, but this depends on economics. It must have enough rf power output and bandwidth to permit its simultaneous use by a number of amateurs. Without going "overboard" and just for discussion, let's assume that it has 20 watts output. The operating frequencies probably should be as high as possible without ruling out general participation by amateurs. Let's choose a satellite with an up-link frequency in the 435–438 MHz band and the down-link in the 144–145 MHz band. The choice of these frequencies is probably rather good because on 435–438 MHz, remember, the ITU has told us that we must have the capability of eliminating potential interference to other shared services in that band. Obviously, it is easier to prevent interference from the ground than on a satellite. On the ground we can realize substantial antenna gain at that frequency. This *could* be done on the satellite but there are other aspects to consider. As an aside, one of the currently planned satellite experiments in conjunction with ATS-G will be using a 30 ft dish in space, having a gain of 18 DBI (Syncart).

To the uninitiated, some of the terms used in space work are confusing. We don't speak of field strength in microvolts per meter, but of power flux density, DBW/M^2. The origin for this and other terms came from the field of micro-wave communication where they speak of signal levels in terms of quantities of energy (flux) per unit area. The term DBW/M^2 simply means a number of decibels above or below 1 watt of energy or power (flux) per unit area of 1 square meter, and is spoken of as power flux density. In order to relate pfd to something all hams are familiar with, keep in mind that 1μV/M of field strength is about equivalent to −147 DBW/M^2. So this gives us an understandable relationship between power flux density in DBW/M^2 and electric potential between two points in space, measured in μV/M. The rest of our discussion is mainly simple arithmetic concerning what we can do with our satellite.

Suppose that amateur "A" wants to have a QSO with amateur "B." The former has a 100 watt transmitter with an emission bandwidth of about 20 kHz, and a dish or a phased array having a gain of 15 dB. Therefore, his effective radiated power relative to an isotropic antenna (E.I.R.P.) is +35 dB or about 3 KW. At 435 MHz the attenuation of the signal (commonly called path loss) from amateur "A" to the satellite, a distance of about 22,000 miles, is 156 dB, a negative quantity. So the +35 dB of power has shrunk to a −121 DBW/M^2 by the time the signal gets to the satellite. If we assume the satellite receiving antenna gain is +15 dB, then the signal at the satellite receiver input will be about −106 DBW, about 40 dB above our reference, −147 DBW/M^2, or roughly 100 μVM (we'll leave off the M^2 for it is assumed). So now we have the signal into the satellite receiver.

Let's assume that the satellite receiver we have in mind has a bandwidth of 200 kHz (which will accommodate about 10 FM signals simultaneously) and has a noise figure in the order of 10 dB, which is about what a real good TV receiver has. Therefore the total receiver noise power in the 200 kHz bandwidth will be about −141 DBW, and amateur "A's" signal is about 35 dB above the noise at the input of the receiver.

If you want 10 or more simultaneous QSO's and we have only 20 watts output from the satellite transmitter, then any one signal should "appropriate" only 1/n times the available power output, n being the number of QSO's. Skipping a little arithmetic related to the satellite characteristics we find that Mr. A's signal of −106 DBW has now become 0 DBW or 1 watt, taking into account the overall gain of the satellite transmitter, transponder or repeater as you will. On the down-link frequency of 144 MHz, the signal path loss en route back to earth is nearly 147 dB. When we boost the 1 watt output by the satellite antenna gain of 10 dB, and then lose the 147 dB, we reach Mr. B's antenna at a signal level (remember we now call it power flux density, PFD) of −136 DBW. Add to this the receive antenna gain of say 10 dB, plus a receiver with a noise figure of less than 6 dB and the result is a signal-to-noise ratio of about 28 dB.

GREAT . . . only in practice it won't be quite that good because of inter-modulation among the 10 or 20 signals passing through the satellite, which will reduce the output sig-

nal-to-noise ratio to a value somewhat below that for one signal . . . say about 20 dB. This is the reason why the receiver noise figure should be as good as possible, in order not to appreciably add to the noise already present on the incoming signal. If we use FM, the output S/N will be equal to the input carrier-noise ratio plus the FM advantage. We now have a satellite about the equivalent in physical size to the original "Early Bird."

One of the greatest problems that amateurs will have to face and overcome (and this is *self-regulation*), is the necessary discipline to maximize use of the satellite. Our postulated satellite can handle about 20 QSO's simultaneously, depending on exact values of bandwidth and power output. But this capability will be realized only if all participants observe self discipline concerning their E.I.R.P. If some amateurs appropriate more than their fair share of the available power through the satellite, it will leave less for others trying to use the system. Another important aspect of discipline will be listening on the down-link frequency to make sure that the proposed channel is clear in both directions. If this discipline breaks down, the result will be not only *QRM in the ordinary sense*, but also *cross-modulation* among *signals of unequal power* in the satellite receiver and thus lower the S/N ratio for everyone using the satellite.

By now you probably have concluded that all is not as simple as picking up your telephone. Depending on economics, amateur satellites may be power-limited. Therefore we should maximime the watt-per-dollar product by choosing up-link and down-link frequencies so that we may obtain as much gain on the earth end of the circuit as possible. All the satellite does is take the up-link signal, boost it by the overall satellite gain, and retransmit it on the down-link frequency. Also these frequencies must be carefully chosen with due regard for electromagnetic compatability on board the satellite, which is a fancy way of saying that we must avoid things like the 3rd harmonic of the down-link transmitter jamming the up-link receiver. Without going into details, the choice of 10 simultaneous QSO's is probably a fairly good figure, even though you are probably thinking "that ain't much." But bandwidth is directly related to total noise power, and if we theorized on 100 QSO's instead of 10 everyone would have to raise his E.I.R.P. 10 dB or the quality of transmission would be reduced.

Probably this is as good a place as any to remark that we seem to always have with us the question of the best way to utilize bandwidth, whether we are concerned with phone and CW on the HF bands – or satellite communication. In the case of our satellite, if we consider the use of CW, it would be possible to hold simultaneously 200 QSO's on the basis of 1 kHz required bandwidth per signal. If you could accept a lower minimum bandwidth of say, 200 cycles per signal for CW (which is probably impracticable), we could accommodate 1000 QSO's . . . always keeping in mind the disciplines we mentioned earlier plus a few I haven't touched on. Probably the best and most acceptable solution, as in HF, is neither all phone or CW, but a reasonable mix of both. But in the satellite case, there has to be world-wide adherence to the disciplines built into the system, or the satellite will not function to greatest advantage.

Up to now we have covered the satellite itself, what it could do and the limitations that may be imposed. But to what purpose do we put it? If we are able to convince others that such a satellite is worth the investment, surely there must be some useful purpose. I would not suggest that we should never use it for some or all of the purposes that have been mentioned such as a *"Satellite DXCC"* a *"Satellite WAS,"* an *"All OSCAR BPL"* or perhaps even for just rag chewing. But I have a feeling that these things by themselves will not justify such a satellite. It seems to me that one of the greatest uses of such a satellite *can and probably should be for educational purposes* not only to train our own young people in the techniques of satellite communication, but also others around the world . . . using the satellite for the exchange of information, advice and actual experience in satellite communication. The so-called "new and developing" countries of the world have not yet reached an acceptance of amateur radio as a worthwhile utilization of the radio spectrum. Perhaps if they see a benefit such as this, it would impress them with the tremendous promise that amateur radio can have for them in the development of trained people in telecommunication. In the plenaries of the ITU, I can assure you, we need their support.

There is another purpose of such a satellite that should be thoroughly explored. Perhaps it is significant that *none* of the currently utilized or contemplated commercial satellite systems are specifically designed for use in the event of a natural disaster, epidemics, famines, floods, earthquakes, tidal waves and similar things which afflict mankind. The need for such a system of communication has already been recognized by the ITU. However, no existing space communication system makes provision for specific channels for emergency communication. Will the amateur satellite service be competent to meet the challenge in extending our charter of 97.1 (A)?

> *"Recognition and enhancement of the value of the amateur service to the public as a voluntary, non-commercial communication service, particularly with respect to providing emergency communications"*

Or are we "just little boys playing in our basements" as we have often been referred to in the assemblies of the ITU? If we *are* up to the challenge and have what it takes, we could create a lasting impression of competence and worthiness in the eyes of world leaders, not just in the plenaries of the ITU

Perhaps it is too large a bite to swallow in one piece, but if we don't seek a larger goal than we have before us at present, what is the future of amateur radio? Are we content to become fragmented among ourselves, arguing like spoiled children about who should occupy what portions of our HF bands, or even VHF, now that we have finally started to earnestly occupy them? Are we fundamentally just a bunch of hobbyists who would idly chatter incessantly over our transmitters which occupy precious spectrum space? How many of you have read recently the basis and purpose of amateur radio contained in Section. 97.1 of the Rules?

What is our responsibility to future generations who will inhabit "our bands" some day when you and I are "silent keys?" Are we leaving them a legacy for the future based on sound judgment and planning? The growth curve of amateur radio in the United States has been more or less static for a number of years. Not so in certain other countries! Novices have constituted about 8½% of our total; Technicians 19%; Conditionals 11½%; General Class 34% and Advanced and Extra Class 26%. Are we attracting a fair percentage of young people to amateur radio? Granted that competition is greater now than it was 50 years ago, but information and learning aids are also more available than they were when you learned the art of wireless communication.

We hear a lot about revolution today in our society. The only apparent impact on amateur radio that I can detect is the increase in illegal operation, the upsurge of foul language to be heard almost any night you turn on your receiver . . . (especially on 75 meter phone) and the apparent desire to lower the qualifications for an amateur license. This is not the kind of revolution we need in amateur radio. If we have the

imagination to confront and reshape it, we might expect that this revolutionary attitude could be of help to us rather than a hindrance, in planning for the future. But if it *is* to be a help, we must present a challenging view of what the young generation can accomplish, not just what they can get out of it in terms of enjoyment because that's not enough. Young people are keyed to a rapidly changing, complex society . . . almost impossible for an older generation to comprehend. Dr. Robert Hilliard explains it with the statement,

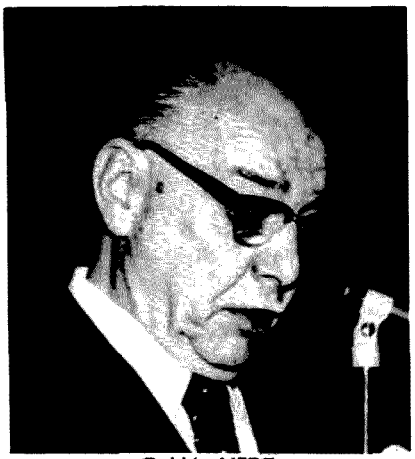
"At the rate at which knowledge is growing, by the time the child born today graduates from college, the amount of knowledge in the world will be four times as great. By the time that child is 50 years old, it will be 32 times as great, and 97% of everything known in the world will have been learned since the time he was born."

Today's youngster generally, is not thrilled by the same things that sent you and me into orbit 40 or 50 years ago. He takes for granted what still gives us goose-flesh in our hind-sight perspective of the development of telecommunication. The frontier of amateur radio is in the field of satellites. I fully appreciate the difficulties of trying to keep abreast of things here on earth. Nevertheless, I urge those who have the responsibility for plotting the future course of amateur radio to look far ahead, lest the immediate problems within and outside our ranks occupy too much of our energies to the long-term detriment of amateur radio.

Over the next few years, I hope the Commission can erect a few new road signs and perhaps replace some old ones, to assist in the development of amateur radio, and keep it going down the right road. Whatever we do, I know you will evaluate it judiciously in the context of our common goal.

In Shakespeare's play *"The Tempest,"* Antonio summed up what seems to me is our position today when he said,

". . . What's past is prologue; what to come, in yours and my discharge."



It is probably significant that the new FCC chief of ham radio was introduced by the newly elected president of the ARRL inasmuch as the powerful coterie of League wheels by no means came to Washington just to hear Walker speak. A highly placed league official, who declined to be quoted by name, told this reporter during the pre-dinner festivities that the group spent Thursday evening with OSCAR and AMSAT officials, and as a result drafted an agreement that would have lasting impact on ham radio in months and years to come. "Really tremendous," was all he would say, "without exaggeration." He refused to divulge any further details, but the impression was left that the ARRL, under the leadership of their new president, would take over OSCAR and AMSAT activities and merge them into the new "professional" satellite program.

Dannals, according to the dinner announcement, was also scheduled to speak, and many looked forward to a major League policy pronouncement. They were disappointed, however, when he confined his remarks to the distribution of some 7 or 8 life memberships and the introduction of Walker.

Another featured speaker was to have been the new president of the national QCWA, Barry Goldwater, W7UGA/K3UIG. He too was anticipated with eagerness, not only because of his U.S. Senate position (R. Ariz.), but also because of his considerable influence in amateur affairs. But Barry bowed out by telegram at the last minute.

Thus Walker had the stage almost to himself, except of course for the venerable Robbie, perennial toastmaster for these affairs. Mr. Harold H. Robinson, W3RE, is a perceptive and progressive thinker, and, despite his advancing years, is younger in mind and in heart than most of his younger contemporaries. Robbie and Mac Williams, K3AC, are wholly responsible for the success of these affairs over the past years.

The League has its dissident members here in the Washington area, however. One such, a ham of long standing and a loyal life member of the League, deplored the often untrue statements in the pages of QST concerning League activities. Also declining to be named, this Washington ham cited the minutes of the Directors' meeting and the editorial (p. 9, March) in QST concerning the outgoing president. "'. . . announced he would not be a candidate' indeed!" this ham said. "It is common knowledge that WØDX expected reelection as a matter of course, and was very upset when he was told two days before the election that he didn't have a chance. When Dannals was elected unanimously . . . " and here words failed him. When asked how he felt about the future under the new leadership, he replied, "U.S. amateur membership in the ARRL, its alleged representative society, is now only about 30% while in other countries ham membership in counterpart societies is between 80 and 90%. The outgoing president was a figurehead, a lousy director. This new man is a doer, full of pep, and capable. I think we are now in good shape. That's why I bought a life membership."

Robbie, W3RE.

200 years of hamming. Gus Gironda, W3JE, president of the Quarter Century Wireless Association, awards 50-year certificates to Charles Stay, W4HE, Edward Clammer, W3UN, Elizabeth Zandonini, W3CDQ, and Charles Lewis, W3AXW. All four recipients of the award have been active continuously throughout the half-century.

One highlight of the evening occurred when, just as Walker was getting warmed up, a shirt-sleeved attendant approached the lectern with a note and asked Walker to announce it to the audience. Walker took the note and read, "Cadillac sedan – several years old – 151713 – what about it?" The attendant announced, for all to hear, "The motor's running." Walker said, "Honey, that's your car." and Mrs. Walker left the room to remedy the situation.

Earlier, Walker had told the following story: "The other day I was discussing ham radio with a good Catholic priest neighbor of mine, name of Father O'Malley, and in the discussion I mentioned the name of Bob Booth (W3PS, ARRL General Counsel), and he wanted to know who Bob Booth was, and I said, 'Why, do you know him?' and he said, 'No, but his name comes up frequently while I hear confesssions.' " When asked later what Walker had meant, Booth, red-faced, replied, "I don't know, but I'm damned sure it wasn t complimentary."

All in the spirit of good, clean fun.

The basics of how noise in various forms limits the performance of receiving antennas and systems is explored. The subject of ultra-miniature antennas is also covered.

NOISE AND RECEIVING ANTENNAS

One of the topics that the newcomer (and some oldtimers) find confusing is the relationship of noise in its various forms to the performance of receiving systems. Or, thought of in a different way, the subject of how sensitive a receiving system should be and what the ultimate degree of usable sensitivity is for a receiving system. This article discusses these topics in a general and nonmathematical manner. The mathematics of receiving systems with terms such as signal-to-noise ratios, noise factors, dBm sensitivity levels, etc. is not extremely complicated once one has developed the necessary conceptual background. However, for many amateur purposes, the mathematics of receiving systems need not be indulged in simply to experiment with the improvement of a receiving system. The main requirement to perform meaningful experimentation that is directed in a useful direction is simply to understand the interrelationship of the various elements in a receiving system and how changes in the characteristics of one element affects the overall receiving system.

Basic Reception Criteria

For the purpose of understanding a transmitted signal, the signal as it appears at the output of a receiver must be a certain level above the background noise. This criterion is true for CW and voice reception where an operator is the final "processing" device in the receiving system. Such a criterion may not be true for the transmission of signals which are completely electronically processed. The amount by which the intelligence signal must be above the background noise for an operator to be able to understand the intelligence depends upon several factors. For a highly experienced CW operator, a CW signal may only have to be a few decibels above the noise level to allow solid copy. For "voice," some words may be heard when the signal is only a few decibels above the noise level, but complete understanding may require the signal to be 10–20 dB above the noise level.

These considerations are further complicated by the fact that if the receiving operator has some foreknowledge of what is being transmitted, he will automatically start to fill in missing portions of a transmission.

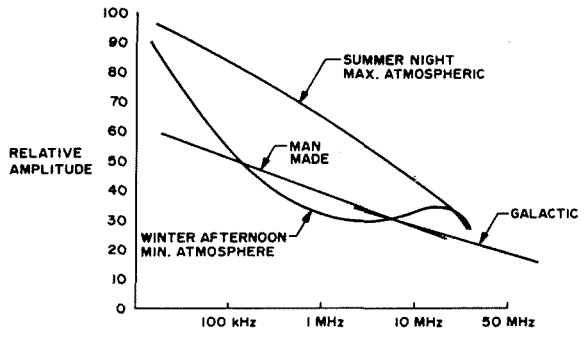

Fig. 1. The main sources of noise that influence reception. The exact amplitudes depend upon location. The relative amplitudes shown are those typical of the Middle Atlantic Coast.

CW4-C.W. FILTER
Now, regardless of the price of your receiver or transceiver, you can copy C.W. with en el most QRN and QRM free signal. Simply add our CW4 transistorized active audio filter and cut the received signal bandpass from several thousand hertz down to approximately 400 hertz. This filter is inserted between your receiver output and speaker or phones. The only thing you add is a 9 V transistor radio battery and the filter is ready for operation. The filter is available in two models to best fit your requirements, deluxe with case, and basic, without, for mounting in your equipment. CW4D (Deluxe with case) (Post Paid) $19.95 CW4B (Basic without case) (Post Paid) $16.95

This sort of situation occurs quite often – for instance, when a contact has been established and the usual "RST, QTH, and name" information is sent. Many QSOs fall apart after such information is sent because the receiving operator no longer knows what to expect (this assumes that the code speed proficiency of the receiving operator is always adequate.) So, there is a basic human characteristic involved in any type of CW or voice reception and the only overall definitive statement that can be made is that the human operator for aural reception requires the received signal to be some level above the noise level to extract intelligence from it.

Noise in a Receiving System

Starting back at the transmitter, and assuming the noise output of the transmitter is insignificant, the signal radiated in the immediate area of the transmitter is many times stronger than the electrical noise level. As the signal is propagated, its intensity decreases. At the reception point, the signal level will have some level as compared to the noise level at the receiving site. The noise level at the receiving site can be a combination of many things – atmospheric, man-made, and cosmic noise. Some of these noises are shown in Fig. 1. along with their variation with frequency. As can be seen, atmospheric noise can vary with time of year as well as with frequency. It also varies considerably with location. The type of noise which predominates depends upon a particular location. Man-made noise is a particularly unknown factor in any location. The other noise sources lend themselves to prediction and calculation, and many charts, maps, etc. can be obtained relating to them. The very simple but still important consideration at this point, however, is that a desired signal (Fig. 2) arrives at a reception point with a definite level as compared to the noise at that point. Aside from the possibility of eliminating man-made noise, there is nothing that the receiving operator can do about this ratio of signal-to-noise level.

The next step in the receiving process (or perhaps the first step, depending upon how the process is defined) is the coupling provided by an antenna. The idea of an antenna as a coupling device is convenient for remembering that it couples both the signal and external noise to the rest of the receiving system. Unfortunately, this coup-

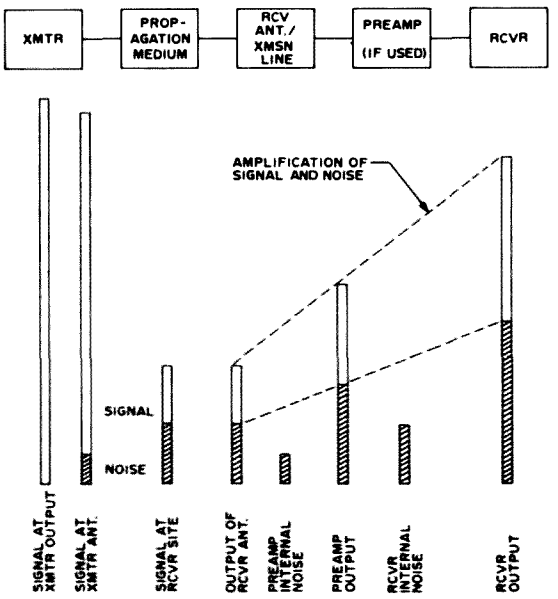

Fig. 2. The effect of noise and amplification at various steps in the transmitter output to receiver output chain.

ling process requires some kind of current flow and any kind of current flow is going to produce more noise. The noise produced is directly related to the losses in the system. These losses (attenuation) reduce the amplitude of the coupled signal and noise, but also introduce new noise. The fact that the amplitude of the signal and noise take on a new ratio is what makes the receiving system suffer – not the simple attenuation of the desired signal alone. For the moment, let us assume that the signal-to-noise amplitude ratio does not suffer during the antenna coupling process.

The next noise source encountered is that provided by a preamplifier, if such a device is used. As shown in Fig. 2, this noise source is shown to have a level less than that of the noise portion of the signal and other noise coupled into it. The amplifying device amplifies both the signal and the noise coupled into it. The output, then, is an amplified signal, amplified noise, and noise generated by the amplifying device. If the amplifying device is good, the signal-to-noise level ratio at its output will almost be the same as that at its input. But it can never be better.

If a signal-and-noise input is coupled directly to a receiver where the noise input is less than that of the receiver noise, the latter will "mask" part of the signal and a poorer signal-to-noise level ratio will occur at the receiver output than was coupled into it.

On the other hand, if the receiver-generated noise level is so low that it is always exceeded by the noise portion of the signal and noise input to it, a preamplifer has no value. The use of a preamplifer in such a case will make things sound louder, but it cannot improve the signal-to-noise level at the output of the receiver over what that ratio would have been if the input signal has been directly processed by the receiver. In fact, if a poor preamplifer is used which has an internal noise level greater than that of the receiver itself, the use of such a preamplifier will actually degrade receiver performance.

It should be noted that in all the signal transfer, processing, etc. which takes place, the objective is to *preserve* as much as possible of the original signal-to-noise level of the input until it can be amplified to the point where it is capable of being used to drive an audio transducer. If one remembers this simple idea, it will be obvious why losses have to be avoided as soon as possible in the receiving process, why preamplifiers should be placed as early as possible in the receiving process, and why a preamplifier, to be useful, has to be a very low-noise device.

The Receiving Antenna

From the foregoing, it would seem that the minimum requirement for a receiving antenna is that it just be large enough to pick up enough external noise to exceed the noise generated internally in the receiving system. Any signal could be received,then, since any signal to be useful anyway must have a level which exceeds the external noise level. This idea is basically correct. What, then, is the value of beams and other very directive antennas for *receiving* purposes?

A beam may have a transmitting gain of several decibels or more but it is still a passive device and, as such, cannot amplify any signal. It cannot produce a gain for receiving purposes in the sense that it amplifies a received signal. What a beam or other directive antenna can do is illustrated in Fig. 3. The omnidirectional antenna picks up both noise and signals from all directions. The directive antenna picks up signals from one direction but, more importantly, also only noise from one direction. The signal-to-noise ratio at the antenna terminals is enhanced in the sense that the total noise pickup of the antennas has been reduced.

It should be noted that the terms "gain" and "directivity" are related but have dif-

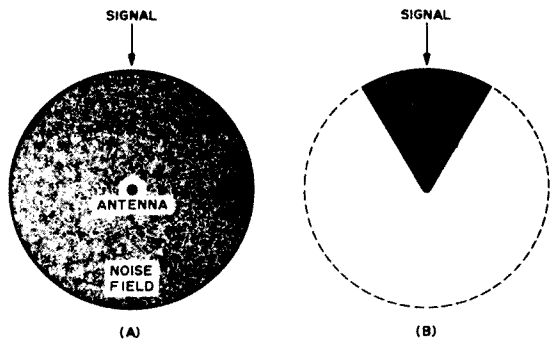

Fig. 3. The value of antenna directivity (B) for receiving purposes over an omnidirectional response (A) is that noise coming from directions other than that where a desired signal originates is discriminated against.

ferent definitions. Both can be expressed in terms of decibels and for some antennas, their value is the same. A large beam has gain for transmitting purposes and also exhibits usually an equal amount of directivity for receiving purposes. A very small antenna can still have directivity (a loop, for instance) but absolutely no gain.

If a very small antenna can exhibit the same directivity for receiving purposes as a large antenna, the question naturally arises as to why a small antenna should not be used instead for receiving purposes. Then, if one could only erect a modest type of transmitting antenna, it still would be possible to have a very effective receiving antenna. The situation becomes even more intriguing when one considers that, theoretically at least, a very small physical antenna provides the same amount of signal pickup as a large antenna. The amount of signal pickup of an antenna itself is not a direct function of its physical size. The advantage of a full-size antenna is that its terminal impedance is such that it matches to a transmission line or some sort of simple coupling circuit and, therefore, an efficient transfer of power from the antenna can take place.

The recent work which has been done on miniature or ultraminiature antennas has been directed toward finding an efficient method to transfer power from the physically small antenna. Transistor stages have been used as a coupling device instead of tuned circuits to match the highly reactive terminal impedance of an antenna very short in terms of wavelengths. Another approach has simply been to use an antenna length just long enough which would theoretically pick up enough atmospheric noise to be greater than the internal noise level in a receiving system. Such an antenna need only be a few inches long, for instance, at almost any frequency above the medium-wave band. The antenna is fed into a preamplifier stage with an extremely high input impedance so that the antenna is not "loaded down." Whatever approach is used, however, the factor of noise still enters into the picture because of the transistor stage used as part of the antenna (whether the stage is called a matching stage or a preamplifier). Active antennas do work, but the question of whether it is worthwhile to very carefully construct the active antenna using very low noise components, or simply to try to make a conventional antenna form electrically larger (perhaps by loading techniques) is a moot one. After all, there are very few situations where one cannot put up some sort of antenna that is more than a few inches long.

Noise Tests

Even with just *some* understanding of the role that noise plays in a receiving system, one can make some subjective analysis of what effect various components have upon a system. For instance, if the terminals of a receiver are resistor-load terminated, the antenna peaking control should produce a distinct increase in noise level at some point. With a terminated transmission line added to the receiver, the same peaking action should occur and the noise level output should be the same or slightly greater than before. If a preamplifier is used and its input terminated, the noise level should not increase if the receiver gain is adjusted to compensate for the gain of the preamplifier.

The best way, of course, to check the effectiveness of a preamplifier, or any similar device added ahead of a receiver which is supposed to improve its performance, is an actual reception test. If the preamplifer is switched in and out and a very weak signal can be heard with the preamplifer that could not be heard without it, you can be sure that the preamplifier has value. Note, however, that if a signal that can be received without the preamplifier simply sounds louder with the preamplifier being used, this does not signify anything about the preamplifier except that it produces some gain. Antennas can be checked against each other by being careful to keep the gains in a receiving system constant and noting which antenna, or what modifications to one antenna produce the best signal-to-noise level at the output of a receiver regardless of how "loud" a signal may sound. If the signal-to-noise ratio is the best possible, "loudness" can be provided at any point in the receiving system by means of additional gain.

The Sewerpipe Antenna

The perhaps unfortunate name for this otherwise superb antenna derives from the fact that the chromium-plated brass tubing used as a matching section (normally obtained along with some funny looks from your friendly local plumbing supply house) was originally manufactured for quite another purpose.

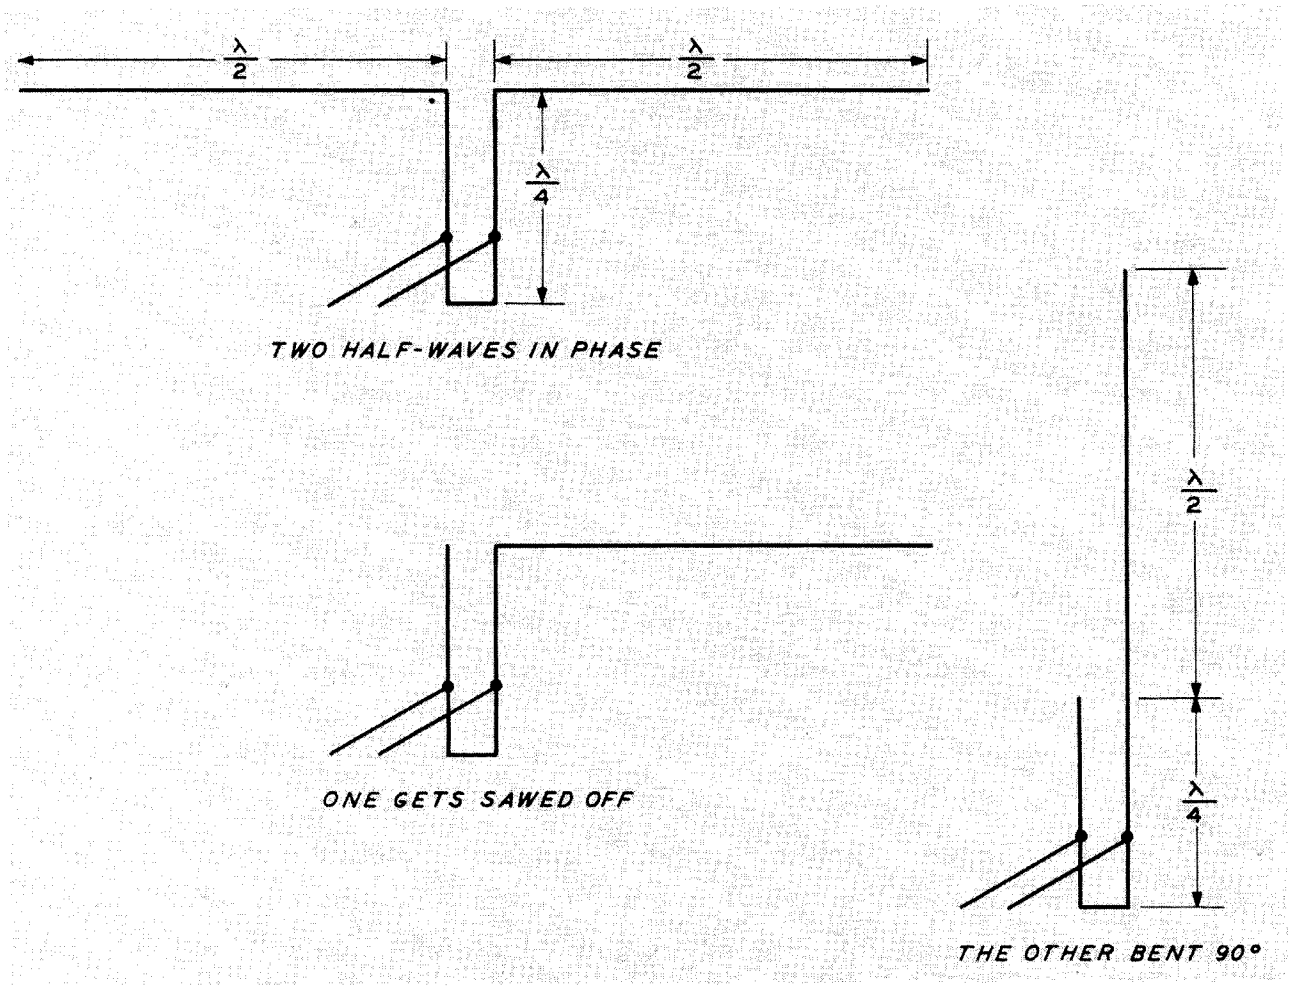

Fig. 1. Evolution of the J antenna.

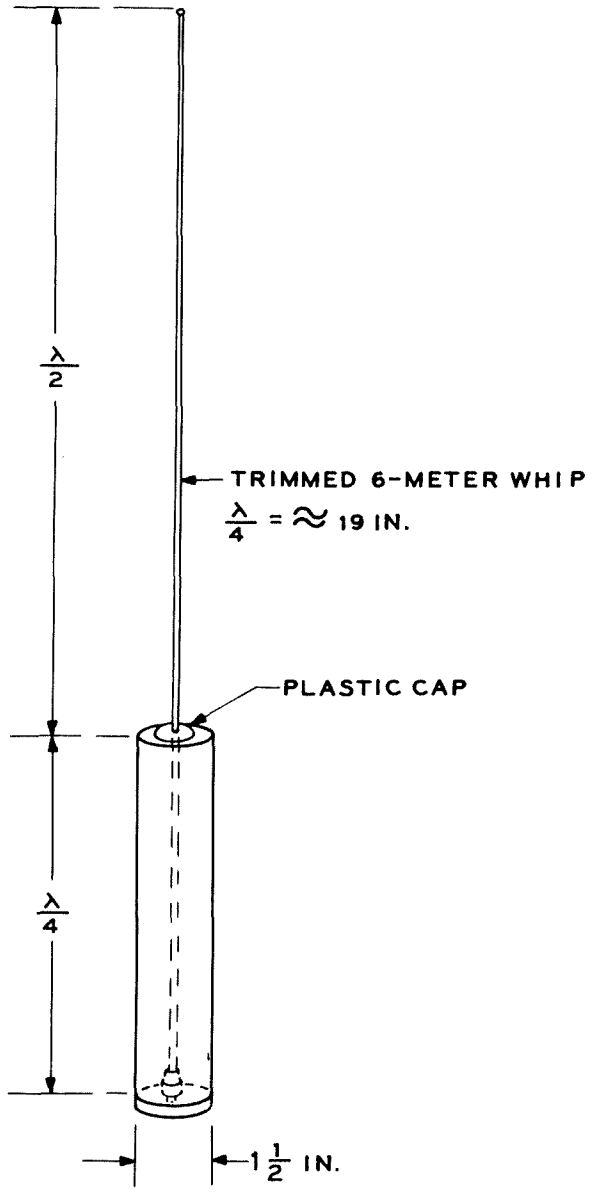
It all starts with the J antenna, the evaluation of which is illustrated in Fig. 1. The J consists of a balanced quarter-wave matching stub feeding an unbalanced load as shown in Fig. 1 (C). But since balanced stubs work best with balanced loads as in Fig. 1 (A), some means of compensation must be provided to make the J workable.

Because of the unbalanced load on the matching section of a J antenna, the currents in the matching section are no longer equal and opposite, so the matching section radiates also. The resulting imbalance also couples rf currents to the supporting structure and the feedline, distorting the radiation pattern and making the antenna diffiuclt to match.

The step from the J to the *sewerpipe* arrangement is simple. Use an unbalanced coaxial matching section for the unbalanced half-wave load. Adjusting the antenna's impedance to 50Ω is easily accomplished as shown in Fig. 2.

Chrome-plated brass pipe of 1½ in. diameter is recommended for the matching section. If ordinary brass tubing is used, then a brass plug for the bottom can be turned to fit the tubing. Mechanical details are dependent upon the materials available, and will be left to the ingenuity of the builder. Dimensions are not critical, but things should fit together tightly. The inside depth of the matching section should be about 19 inches. Keep the plastic cap (Fig. 2 (A)) thin and use low-loss dielectric material, as this is a high voltage point. The internal feed assembly is physically similar to the gamma match used for unbalanced feed of a yagi antenna (omitting the series capacitor, of course). A clamp (Fig. 2 (B)) comples the connection from the off-center coax to the center conductor. The height of this clamp and the center-to-center spacing of the off-center member is varied to obtain a perfect match to 50Ω.

An interesting variation on the original sewerpipe antenna was developed by Prof. D. K. Reynolds (K7DBA) of the University of Washington. A different feed technique is employed, as illustrated in Fig. 3; the result is an ideal antenna for base station use. Antennas of this type are in use at Byrd



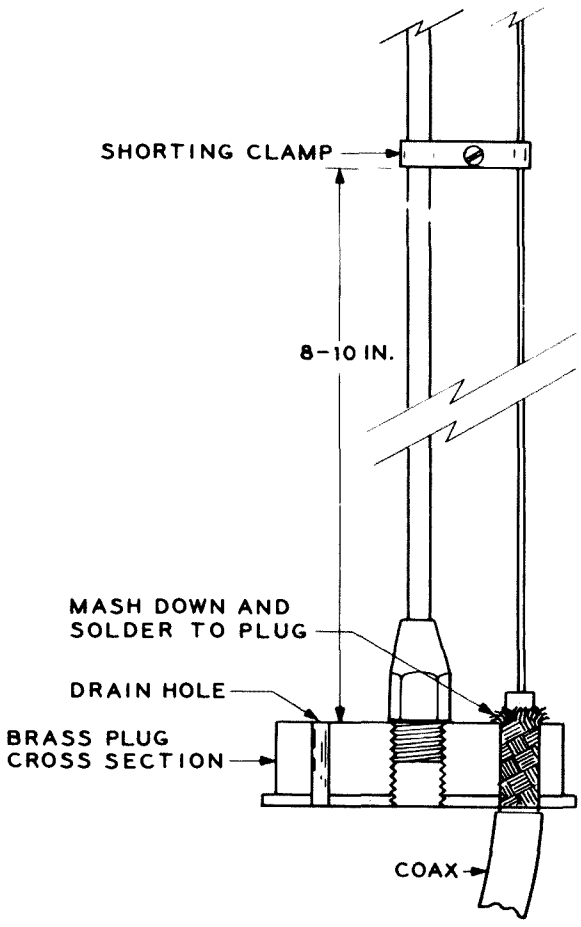


Fig. 2. The sewerpipe antenna.

VLF Substation, Longwire, Antarctica, home of the 21-mile dipole. There they use 146.76 MHz VHF/FM for both on-site and station-to-station communications.

Semigrid coax is used, and the 60Ω section is made by removing alternate half-inch sections of the dielectric inside the coax for about 16 inches. This raises the characteristic impedance from 50 to about 60Ω. The original version is more suitable for mobile use, however, because of its greater rigidity and mechanical strength.

Patterns taken at the University's antenna range show an almost perfect free-space dipole pattern. The measured gain over an isotropic antenna was 1.62 dB as compared

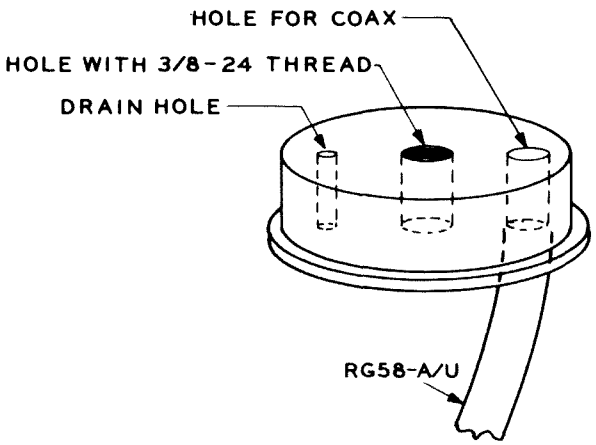

Fig. 3. Plug details.

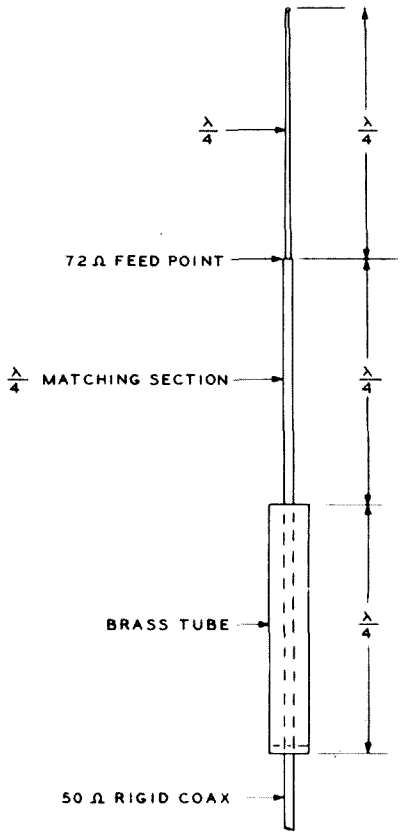
with the theoretical value of 1.64 dB for an ideal dipole antenna. These antennas are unbelievably well decoupled from their supporting structure and are therefore a breeze to match. The only significant current is on the antenna itself.



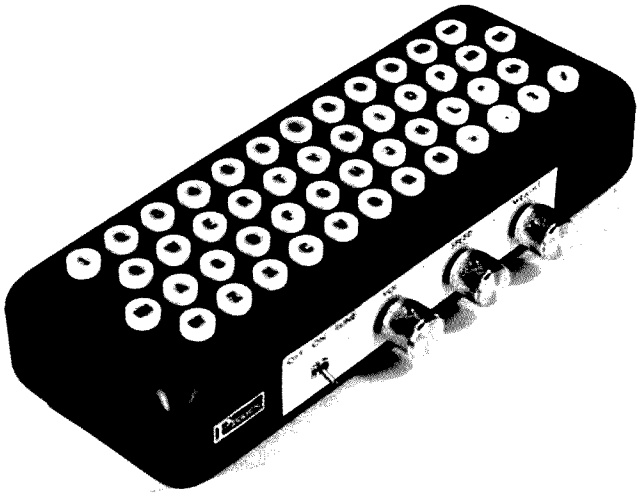


Fig. 4. Reynolds modified sewerpipe antenna.

Since no claim is made for extra gain, then where is the claimed improvement over other antennas? Basically, it is in the reduced angle of radiation. Practically speaking, most mobile antennas at two meters -- whether ¼ or 5/8 wavelength – have about the same gain toward the horizon; moreover, they all suffer to some extent *finite groundplane* effects, which act to lift the angle of maximum radiation intensity above the horizion. Thus the secret of the sewerpipe antenna's performance is its straight-out angle of radiation.

If you live in an area well covered by an accessible repeater and don't stray much, the quarter-wave whip may be just right for you. But if you need long-range capability for your mobile, give the sewerpipe a try. They have been widely used in the Pacific Northwest since 1961. The sewerpipe is ignored by all CB'ers (unlike a 5/8-wave whip), but seems to disturb the 75-meter mobile operators for some reason. Could be they think it's a new chrome-plated loading coil.

PICKERING KEYBOARD KEYER

I had the Pickering Keyboard Keyer on my operating desk when an RTTY friend came in. "Don't you have to push FIGS to get numbers and punctuation and then LTRS to unshift?" he asked, forgetting that I didn't even own a printing unit. "No," I said, "this is for CW." "Then how do you send the dits and dahs?"

The Pickering Keyer is a fascinating unit that eliminates the mental gymnastics of translating letters into Morse code sounds. Lightly touching any of the glare-free buttons, even for an instant, will produce the Morse representation of the character. All letters, numbers, punctuation, and ham procedure signs ($\overline{AR}$, $\overline{BT}$, $\overline{SK}$ . . .) are self-completing once they have begun. For example, to send CQ, just touch C and then Q. Unfortunately, there is no memory for letters as there is for a dit or dah in conventional keyers. While the C is playing, the Q should be held down. This Keyer will complete the C, insert the correct between-letters space, and then it will send the Q. Longer words can be sent by touching the first letter and while it is being sent, hold the second. Once the second has begun, move your finger to the third and hold until it begins, and so on. Letter spacing is automatic; word spacing is up to the sender.

Obviously it is necessary to be familiar with a typewriter keyboard and a knowledge of touch typing is an asset. Knowledge of CW is still necessary to know when to move fingers from letter to letter. Since some letters are shorter than others, at higher speeds you have to be quick. The speed is adjustable by a front panel control from about twelve to seventy words per minute. Slower speeds are possible by increasing letter and word spacing. The dit length can be varied by the weight control. Some keyers are pre-adjusted for weight, but being able to adjust it is an advantage because copying ability can change with dit length, depending upon the rate at which CW is being sent. The letters will be sent in perfect form.

How easy is it to use? Very. First, plug the unit in and hook up a loudspeaker or headphones to the appropriate jacks on the rear panel. Turn the KB-1 on and press a few buttons to get the feel. Very little pressure is required to activate the IC logic systems to send letters. The keys have a barely perceptible movement and this makes rapid finger placement possible. The monitor produces a low pitch tone that is easy to hear above background noises without blotting them out. The volume level is an adjustment on the front panel. After practicing for several hours it becomes second nature to push a

Name_____ Call _____

Address _____

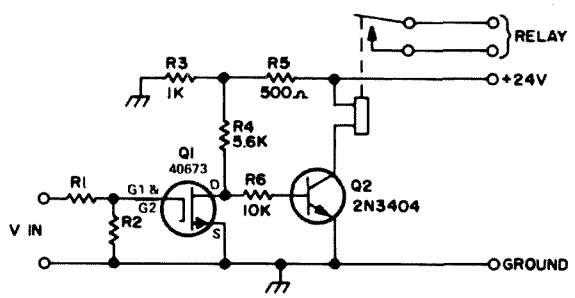
City/State/Zip_____

button and to hear the correct letter emerge from the monitor. Finger placement, even for a hunt-and-peck typist, becomes easy and rhythmic. Adjustment of the keyer speed to a comfortable rate coupled with a relaxed typing speed still allows the hunt-and-pecker to send perfect CW at speeds up to twenty words per minute. The Pickering is heavily weighted and it will not slide across the operating desk. You could even use it sitting upon your lap if you wished to use CW while mobile.

After becoming accustomed to hearing a complete letter in Morse when moving one finger a fraction of an inch, I tried the unit on the air. I told my contacts what kind of keyer I was using and comments included, "That's cheating" . . . "Sounds clean" . . . "Pretty good." Sending became effortless. The hand rhythm developed quickly and smoothly and the letters flowed out as I thought of them. It was a BPLer's dream.

The unit is ideal for code practice sessions, as we use it here at 73. It is easy to pick the unit up and carry it to classes, and even a beginner can send perfect code without even knowing it. This new dimension to learning also allows the sender to learn characters and spacing. The speed can be adjusted to a moderately high rate and long spaces can be inserted to give the impression of slower speed. This, incidentally, is the newly approved method of teaching CW: fast letters with long space. It allows the listener to adjust to the concept of shorter letter timing, just like he will get in actual copy off the air.

To hook it up to your rig requires looking at the transmitter's schematic. You must determine the voltage across the key, positive or negative, in order to connect the cable to the correct keyed output. This protection is necessary to protect the integrated circuits that make up the circuitry. If you make a mistake, no damage occurs.



For the ham who takes Morse code seriously or for the professional code practice instructor, the Pickering KB-1 Keyboard Keyer is an indispensable tool for perfect CW. True perfection costs only $265 from the *Pickering Radio Company, P.O. Box 29, Portsmouth RI 02871.*

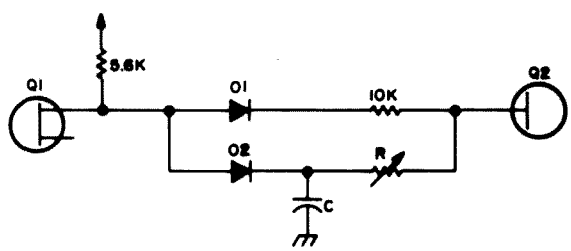
SOLID STATE CARRIER OPERATED RELAY

There is a very versatile carrier operated relay which is adaptable to many supply voltages and can be used with either tube or solid state receivers. The circuit as shown operates on the standard 24V control voltage.



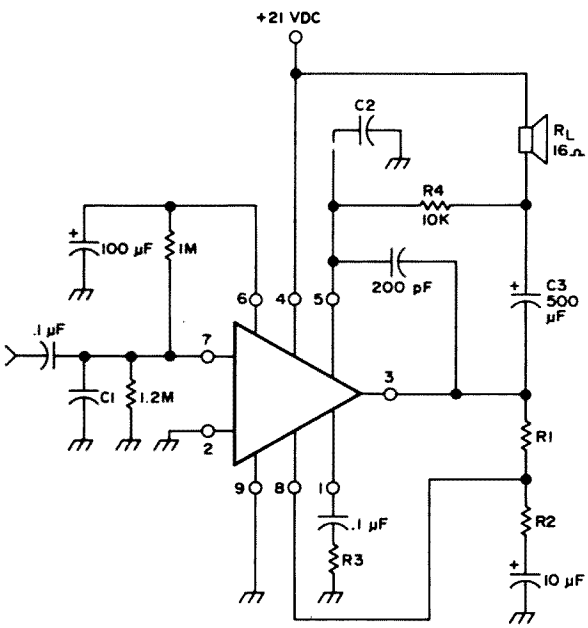
The first transistor stage utilizes a MOSFET with an extremely high input impedance. This feature allows connection to nearly any receiver with a minimum of loading. A negative going voltage of more than −3V is required to activate the COR. This voltage can normally be obtained from within the receiver squelch circuitry. With no received signal V_{in} should be approximately 0V.

R_1 and R_2 are chosen so that the gate to source voltage (V_{gs}) is at least −3V with a received signal. But not more than −6V. For V_{in} in the range −3 to −6V R_2 may be eliminated. Typical values are in the range 1−10 MΩ. Q_1 is conducting sufficiently during no-signal conditions to prevent sufficient base current from turning Q_2 on. When a signal is received Q_1 is cut off driving the drain potential up and the base of Q_2 receives adequate current to saturate, causing the relay to be activated. Q_2 is a standard NPN bipolar transistor with a high h_{FE} (dc beta). R_3 and R_5 are used to limit V_{DS} to +15V.

For 12V operation, R_3 and R_5 are eliminated, R_6 is reduced to 5.6K and a 12V relay is used.

With the addition of only 4 components the COR can be given a variable release (hold timer) function. Shown schematically below the relay can be set to provide up to 30 seconds or more of hold time after the carrier has disappeared.

D_1 and D_2 are 50 PIV 100AM diodes. The hold time is determined by the RC product. Typically, the C of 200 μF and R of 5K the hold time was 10 seconds. Values will differ from transistor to transistor and should be determined experimentally.



This solid state COR should provide you with a low power (.4W max) yet flexible device for your repeater or other carrier signaling functions.

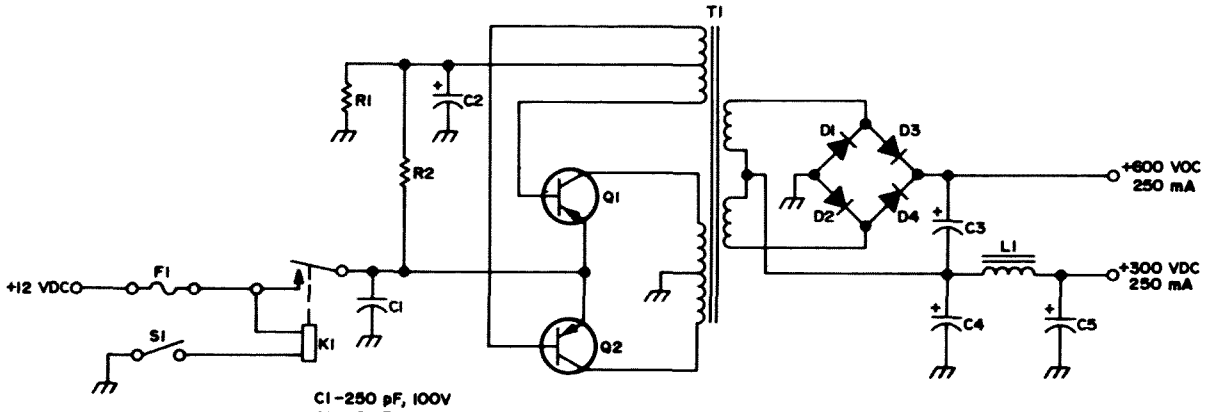
Typical application and test circuit (10-watt amplifier) using a Motorola MCF8020 class B audio driver silicon monolithic functional circuit. The MFC is designed as a preamplifier and driver circuit for complementary output transistors and will drive up to 15 watts output (4 ohm load). Application circuit courtesy of Motorola Functional Circuits Handbook.

Low frequency preamp 1 Hz to 50 kHz, voltage gain 400, extremely low noise, all capacitances in μF, all resistors ½W, transistors 2N5486. Circuit thanks to WA3EEC.



Q1 – VHF PNP (GE-9, ES19, etc)
* – MAY BE NEEDED IF TRIMMER WILL NOT ZERO-BEAT. ADD IN 50 pF STEPS.

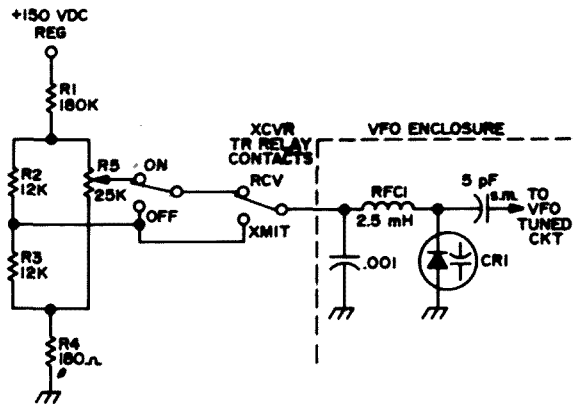
One-transistor radio. Works on local broadcast stations. Amuse the Jr. op. Circuit courtesy Calectro Handbook. L1 is a ferrite variable antenna coil (Calectro D1-841). D1 is and signal diode (Calectro K4-550).

Two meter crystal oscillator. The transmitter crystal is used, the netting capacitor is adjusted so that the crystal is zero-beat with someone who is considered as being on frequency. Then the oscillator may be used to align a receiver. Since the output is so high (measured 18 volts peak to peak across the choke), it must be loose coupled to the receiver. This is done by winding two turns around the choke. One end of the winding is connected to the connector; the other end is connected to a 51 ohm resistor, which is then connected to ground. This circuit is very active and will handle crystals from 2 MHz to 30 MHz. (Thanks to VE7AZH.)

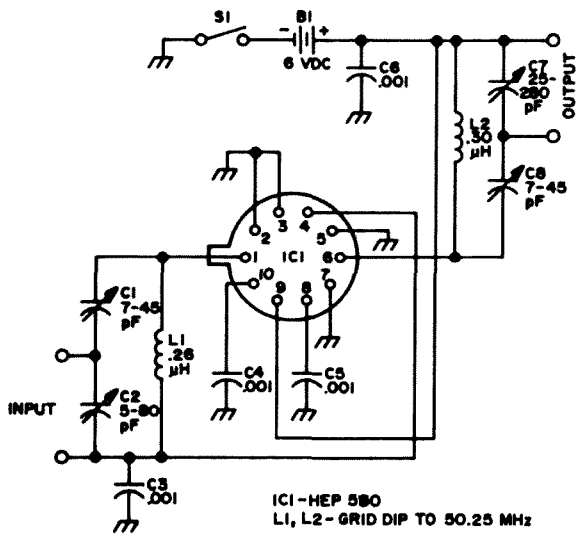
Mobile transceiver power supply (from The Keyer *Ventura County ARC). 12V in, 600V @ 250 mA and 300V @ 250 mA out. Mount transistors on heatsinks.*

INDEPENDENT RECEIVER TUNING FOR TRANSCEIVER

Did you ever wish you could tune the receiver section of your transceiver without changing the transmitter frequency? Sure would be nice on CW for setting the tone of the station you are working, or for SSB roundtables where everyone never seems to be on the same frequency. It is extremely simple to do if you have an extra set of contacts on your TR relay in the transceiver, or room for another relay. Stability is not affected; however, the vfo must be recalibrated. Such a device has been in use here for about three years, and I would be lost without it.



Referring to the drawing, CR1 is a Varicap Diode Motorola MV1642 or Hughes 1M954. It changes capacity as the voltage to it is varied (working like a variable capacitor). When transmitting, the diode is given a steady voltage from the voltage divider R1, R2, R3, R4. When in receive, the potentiometer R5 is supplying the voltage to the varicap. With R5 in the center of its range, the control voltage is about the same as in transmit, so there will be no offset. Moving R5 above or below center will tune the receiver plus or minus from the transmitter frequency. Switch S1 bypasses the offset control and allows normal transceiver operation.



C1, C2, RFC1, and CR1 should be mounted inside the vfo enclosure. The other components can be anywhere, including a separate box outside the transceiver. Recalibrate the vfo with the switch in the off position. As shown, the offset is about 2 kHz. If you want more offset control change C2 to 10 pF.

I hope receiver offset will increase your operating enjoyment as much as it has mine. Cost is $6 or $7 if all parts are new.

. . .W2FBF

Circuit courtesy WCRA SCOPE.

Six meter pre-amp with 30 dB of signal gain and 600 kHz bandwidth. The input and output impedances are matched. AGC may be added to pin 5. For FM use dip the coils to 52.5 MHz. SIGNAL REPORTING -A RECAP

Like all of man's methods of measurements, our RST (readability, signal strength, and tone) system for giving signal reports have come down to us through a long and painful evolution. The fact that it has been used, unchanged, for more than a quarter century, indicates that the end product has been pretty successful.

There were lengthy times of mild confusion when, in transitional periods, more than one code was in general use before blending into another. It also took a long time for the idea to emerge that readability and signal strength had to be treated as separate entities.

Any ham with enough whiskers to join the Old, Old Timers Club (I.E., licensed 40 years ago), will recall the original R scale (for readability), also known as the Eccles code:

R1 Faint signals, just audible
R2 Weak signals, barely audible
R3 Weak signals, copyable in the absence of any difficulty
R4 Fair signals; readable
R5 Moderately strong signals
R6 Strong signals
R7 Good signals, such as copyable through interference
R8 Very strong signals, can be heard several feet from phones.
R9 Extremely strong signals

There may have been older reporting systems in ham radio, but this one was proclaimed official by *QST* in 1925 and must date back at least to World War 1. Its long-term impact on the art may be shown by the fact that it wasn't until the end of World War 2 that our receivers' carrier strength indicators were called S meters rather than R meters! But as the state of the art grew more refined, dissatisfaction also grew because, although the Eccles code was supposed to indicate readability, the definitions were much more concerned with signal strength. It was also pointed out, in later years, that on a receiver with a number of audio amplifier stages, almost any old signal could be made to conform to the R8 requirements by simply cranking up the audio gain.

Along about 1926, RCA originated a system known as the Traffic Frame Code, primarily intended for use by commercial cw stations. The word "Frame" indicated the order in which the five section report was to be given, that is, Frequency, Relative Strength, Amplitude Modulation, Musicality of note, and Estimated readability. Since each of the five sections contained nine graduations, it's just as well that this one was speedily forgotten. But the Frame code was indeed an important part of the family tree because the M for Musicality of note section was lifted in toto to become the T for "Tone" part of our R-S-T code. Witness the original nine parts with the frequent references to musicality:

1 Extremely rough, hissing note
2 Very rough ac note, no trace of musicality
3 Rough, low-pitched ac note, slightly musical
4 Rather rough, ac note, moderately musical
5 Musically modulated note
6 Modulated note – slight trace of whistle
7 Near dc note, smooth ripple
8 Good dc note, just trace of ripple
9 Purest dc note

It's most interesting to note that these nine definitions of a cw note have served us for 40 years without a single word having been changed!

Another early system of signal reporting, intended for use by the then relatively few phone stations, was the Q for Quality code of five divisions:

Q1 Good quality, no hum or distortion
Q2 Good quality, but noticeable hum
Q3 Fair quality because of distortion
Q4 Poor quality because of bad hum
Q5 Poor quality because of bad distortion

From this it may be inferred that hum and distortion were a common part of radiotelephony in those days, which is indeed true (as those of us who were there will attest). If it had been possible to do so, microphones and filter capacitors would have literally been cheaper if fabricated from gold rather than carbon granules and tinfoil.

Meanwhile there evolved a five point reporting system based on the international code signal QSA, "The strength of your signals is . . . " Its final form as adopted by the 1932 Madrid Conference was:

QSA1 Hardly receptible – unreadable
QSA2 Weak, readable now and then
QSA3 Fairly good, readable with difficulty
QSA4 Good, readable
QSA5 Very good, perfectly readable

Even though, here again, readability and strength were somewhat interwoven, these five steps are easily recognizable as the direct ancestor of the R for "Readability" part of our R-S-T system.

Although at the time of its inception, the QSA code was intended to supplant the older nine point R system, hamdom was unaccountably cool to the idea and blithely proceeded to use them both at the same time. During that period, as old-timers will recall, a moderately good phone signal might have been reported as QSA 4 R7 – good signals, such as copyable through interference.

CW stations used the same procedure except the report was preceded by a simple abbreviation to indicate tone, i.e., RAC for rectified ac (or raw ac), NDC for near dc, DC for a nearly pure whistle, and, best of all, PDC for pure, direct current. If the piercing quality of crystal control was evident in those days of mostly self-excited rigs, an X was tacked on ahead of the appropriate group. Thus, a pretty good report in any CW man's log was "Ur XPDC sigs QSA 5 R7 hr, OM."

And so the stage was set for the final (almost) attempt to set up a workable signal reporting system with readability, signal strength and tone in three entirely separate categories.

The first description of the R-S-T code, together with the announcement of its adoption by the ARRL, appeared in *QST* for October, 1934. The readability and tone sections of the new code as then set forth were exactly as they are today – remarkable when one considers the technical changes which ham radio has undergone during the intervening years. As proposed in 1934 the S for strength portion contained only 5 steps:

1 Faint – signals barely perceptible
2 Weak signals
3 Fairly good signals
4 Good signals
5 Very strong signals

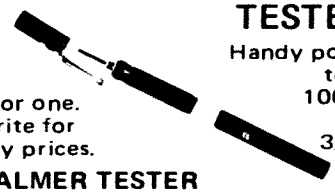
Long accustomed to the multiple possibilities offered by the old R1 through 9 code, the fraternity voiced immediate dissatisfaction over this new, apparently oversimplified version. Also "R" meters were just becoming available on superhet receivers and the gaps between S points looked very wide indeed.

Consequently, only one year later[1] in October, 1935, four additional steps were interspersed to bring the total up to the magical nine total. The added steps: very weak signals, fair signals, moderately strong signals and strong signals. As an afterthought, S9 was changed to "extremely strong signals."

During the years since then, there has been no end to the argument over what constitutes an extremely strong signal. Perhaps our new friends, the Citizens Banders, have the answer – they've simply added an "S10!"

. . .WØHKF

[1] Curiously, although the arrangement was officially in use for only a year, it gave rise to the abbreviated report, still heard occasionally, "Read you 5 by 5" or "5 square."



Lazy Lechers

As was mentioned in the article of W2DXH in *73*, July '66, Lecher wire systems are of questionable value. To the average ham this no doubt is a true and irrefutable statement, and of little value to the vhf or uhf experimenter. However, going into the first stages of second hamhood, the author tried out a pair of Lecher wires last winter.

Since some may ask, "What are Lecher Wires?" and, indeed, some have, a brief description might be in order. Please don't try your secretary's dictionary. Nasty-minded insinuations are all you will find. Just take a double man-sized hank of bare shiny wire, bend it back on itself, stretch tight, and apply a shorting bar of some kind. That is a Lecher wire. Simplicity should not be confused with lack of accuracy. For calibration, measure the distance between nulls or peaks, and convert to meters or frequency. This procedure was plenty good on 5 and 2½ meters in isolated spots where the primary need was to insure you were in the band. For more accurate measurements, a sneaky deal was to use the harmonics of the oscillator of a short-wave receiver to calibrate things. Merely add and subtract 455 and multiply. Meanwhile, back to Lecher wires.

An expensive source of workable wire is aluminum clothesline. Plastic clips cost about 10 cents a dozen with mounting screws. A 1 x 2 piece of wood, a few feet long, is the only requirement. For long term stability, a coat or two of shellac or varnish may help. As for the accuracy and calibration, these are really up to the individual. For an example, the sound and video on channel 7 can be very easily separated. 4.5 MHz at this frequency represents quite good resolution for such a simple instrument. Maintenance costs are extremely low. None!

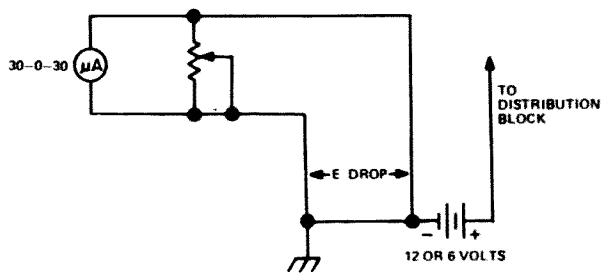
EASY AMPS



Simple ammeter for your car.

Most amateurs belabor the fact that many of the present day American cars come equipped with those questionably functional "idiot lights." The average amateur, not qualifying as an idiot, finds them extremely difficult to read in determining how much current his rig and other accessories are drawing from an already overloaded battery.

The generally accepted method for monitoring current in a vehicle so equipped is to mount an ammeter somewhere in or on the dashboard, break the dc line at an appropriate place, run a pair of heavy leads through the firewall and connect them to the meter.

This has many disadvantages. The last time I tried this using No. 10 insulated copper wire a voltage drop of approximately 0.7V under a load of 18 to 20 amps was noted, not to mention the job of knocking a large size feed-through hole in the firewall. When installing the old rig in a new car, I decided to take a lazy-type approach to this problem of remotely reading current.

This was accomplished by the simple expedient of inserting a zero center 30-0-30 microammeter from the negative battery terminal to any point on the body of the vehicle where a good ground can be obtained. This has the effect of reading the voltage drop across the negative battery cable which is directly proportional to the current flow. In my case, I found that the meter reading was slightly higher than the actual current. This was proved by inserting a standard 0-30 ampere meter in the dc line and observing the current when the lights or

other accessories were turned on. An ancient wire wound, open type potentiometer was "scrounged" from the junkbox and placed across the microammeter terminals. This was adjusted until both meters read the same. The ammeter was then removed and the dc line closed.

A 10 foot piece of No. 18 insulated wire was then connected to the negative battery terminal. This was guided through the cable hangers and through a convenient small hole in the firewall where it was connected to one terminal of the microammeter, the other terminal going to ground. The pre-set pot was soldered across the terminals. The meter was then mounted in a small panel designed to attach to the steering post.

I now have a device with which I can read current charge and discharge with a fair degree of accuracy.

Remember that this scheme involves wiring that is virtually at the same potential as the vehicle body, therefore the danger of short circuits is non-existent. The main advantages of this simple installation are: elimination of voltage loss at the load; and ease of installation.

NEW IC TIMER (NE 555)

FEATURES

- TIMING FROM MICROSECONDS THROUGH 1 Hr.
- CAN EITHER FREE RUN OR LATCH
- ADJUSTABLE DUTY CYCLE
- TIME DELAYS CAN BE RESET
- TEMPERATURE STABILITY 0.005% PER °C
- OPERATES FROM 4 to 15 VOLTS FOR 1% CHANGE IN TIMING
- TIMING CAN BE CHANGED 10:1 WITH CONTROL
- VOLTAGE
- OUTPUT CAN SOURCE OR SINK 100mA

$1.50 Each

UNIVERSAL DECADE COUNTING UNITS

1. Easy to read single plane LED or Filament-type Readout with wide angle viewing.
2. BCD Outputs available
3. Readout Lamp Test
4. Selectable Ripple Blanking
5. Selectable Decimal Point
6. Counter Reset
7. Plug-in Module
8. Molex Sockets for all IC's & Readout
9. Tin-Plated G-10, 2-oz Copper, Glass Epoxy Board
10. Your choice of 1 to 6 decades on one P.C. board.
11. Grouping of 2 or more readouts on the same card, for custom designed appearance.
12. 5-Volt TTL compatable single supply.
13. First in a series of universal plug-in modules to be introduced soon; for frequency counting, time measurements, event counting, DVM, magnitude comparison, etc.
14. Well documented application note with step-by-step assembly and hook-up instructions.

Price (Per Decade):

Basic Unit consisting of 7490, 7447, Filament-type 7-segment Readout....$8.00

Options:
For LED Readouts instead of Filament-type add $2.00
For 7475 Latch add...$1.25
For 74176 instead of 7490 add.....$0.50
For 74192 instead of 7490 add.....$1.00
For 74196 instead of 7490 add.....$0.75
For Fully assembled and tested unit add.....$2.50

We have had many calls asking us if the components we sell are rejects? We would like to announce here that EVERY item sold by us is manufacturer's FIRST-RUN, fully tested and in perfect BRAND NEW condition. These parts are purchased through huge blanket orders mainly for our manufacturing requirements, and we are happy to pass on the savings to you. All parts are GURANTEED to be brand new, NOT EVEN SURPLUS NEW; but first-runs, manufactured within the last 9 months.

Manufacturers, schools, universities, hobbyists; we can save you hundreds of dollars on your requirements, while offering a permanent source you can depend on indefinitely, not until one's surplus stock is exhausted.

DELIVERY PROBLEMS? Every item advertised here will be shipped within 24 hours after receipt of your order (3 days for orders paid for by personal checks), or we will allow you a 10% discount on back-ordered items. For SUPER-FAST service give us a call and we will ship COD the same day.

Incandescent Type of 7-segment display. With right-hand decimal point. Rated 8mA per segment at TTL supply of 5V. Design life of 50,000 hours. Needs a 7447 as a driver. In DIP Package. Each $3.25

MOLEX IC SOCKET PINS: Use these economical pins instead of soldering your IC's to PC boards. Sold in continuous strips in multiples of 100 pins only.

100 for $1.00; 200 for $1.80; 300 for $2.60
400 for $3.40; 500 for $4.20; 600 for $5.00
700 for $5.80; 800 for $6.60; 900 for $7.40
1000 for $8.20. Each additional 1000 $7.50

VOLTAGE REGULATORS. Internally-set, overload and short-circuit proof regulators need no external components to set. With data sheet and application notes. TO-3 Package.
LM-335, 5V, 600mA.....$2.85
LM-336, 12V, 500mA.....$3.85
LM-337, 15V, 450mA.....$4.05
20 Watt PC-Board Type HEAT SINK.....$1.20

Amateur Radio

JUNE MCMLXXII Monthly Han

HAMS HELP IN TORNADO CRISIS

Louis R. Huber W7UU

A classic demonstration of a monitoring service's capability in an emergency occurred April 5, 1972, when a tornado struck Vancouver, Washington. Six people were killed outright, with hundreds suffering injuries. $6.2 million dollars damage was done by demolition of a school, a supermarket, a bowling alley and portions of other buildings.

The tornado struck at 12:49 P.M., PST. NAMS (Northwest Amateur Monitoring Service) received the first news of the disaster when K7SUX mobile checked in with Monitor Control (W7DFL Tacoma) as 2:18 P.M. "I'm on my way to Red Cross headquarters," he said. That is also the meeting place for the Clark County Amateur Radio Club. K7SUX contemplated putting the club station on the air; however, it was out of order and he continued to do what he could as a mobile. Later the club station (W7AIA) did get on the air with a transceiver brought down by WA7MQC.

With the first raw news of the disaster from K7SUX, NAMS' cogwheels jumped a bit – wonderment at first, than casting about as to what best to do. WA7NVF and W7ZF in Portland, Oregon (across the Columbia River from Vancouver) were well aware of the vicious wind because of torn-off shingles and other debris flying about. They were on the air along with W7UU, Seattle, and Monitor Control W7DFL.

A local control station was set up on 3960 kHz, with NAMS keeping on as usual on 3970.

About this time WA7KKC, Vancouver, was driving in the tornado-struck area. He had to detour around the devastated area to reach his home and so he knew almost precisely the limits of the devastation. "I'll take it and go down to 3960," said WA7KKC, as soon as he got on the air. This was at 2:40 P.M., less than two hours after the "killer wind" struck. Bill Tuominen WA7KKC, has been a licensed amateur only a little over two years. His performance in this instance, and for the next three days, leaves no doubt as to his proficiency – it was tops!

WA7KCC's son, Monty, was home on vacation from college. He spread out a map of the city and circled the devastated area. "Give us addresses," said WA7KKC, for health and welfare inquiries were already coming in, "and we'll see if they're in the disaster area. That's the best we can do right now."

Bill estimates that somewhere around 1,000 inquiries were handled that same day over his station and others in Vancouver. Something less than that during the next day, plus a few stragglers on the third and fourth days after the disaster. There were probably 2,000 or more such calls. Telephone service was destroyed in the devastated area and remained out locally until mid-afternoon Friday, although some telephones got into operation slightly before then. Incoming long-distance calls were met by a recorded announcement during this period so amateur radio was the only way relatives had for finding out how their kin had fared.

WA7KKC was on the air continuously until 6:30 P.M., a stretch of four jampacked hours. He then drove over to the Red Cross headquarters. By this time W7AIA, the Clark County Amateur Radio Club station, was on the air by means of WA7MQC's transceiver. Bill manned the city map at the club station, checking out addresses one by one as they came in.

Mid-evening brought some phone-patch activity through other Vancouver ham stations; W7EEA, who is totally blind, handled a number of them with great efficiency on 3950 kHz. WA7OAS, Sally, an XYL, with other Vancouver hams had two-meter gear in operation for Vancouver area operation – especially with mobiles. The latter included K7SUX, W7SNY, K7SUQ and others.

The mobiles were used for various chores, checking out details and providing communication where needed by the Red Cross crews.

Although NAMS ceases operation at 5:45 P.M. daily, the 3960 kHz NAMS emergency operation kept right on throughout the night and into the next morning until about 2:00 A.M. Two nets, Columbia Basin and Northwest Eyebank, which normally use 3960 kHz, graciously moved to other frequencies so NAMS could continue its work uninterrupted.

From other points in the Pacific Northwest and West, health and welfare inquiries originated through a large number of ham stations who got in touch with their local Red Cross offices, where such inquiries are placed.

The cooperation of all NAMS members and non-members proves the reliability of this kind of service and the efficiency with which hams can mobilize to perform emergency communications.

HAM OPERATORS AID TANKER

Two ham radio operators who established communications with the Military Sealift Command's *USNS Cossatot* after the ship's system failed have been commended by Marine Transport Lines, Inc., operators of the tanker. John Previtera WB2BAR, Bronx, N.Y., and William Taylor WA3HRO Thorton, Pa., answered *Cossatot* Captain Finn Bjorney's call for assistance, and established a connection with the company's home office in New York City. The tanker was directed to Trinidad for repairs. *Reprinted from the Military Sealift Command Newsletter.*

BY NOAA

$1K RADIOTELESCOPE

Scientists of the Commerce Department's National Oceanic and Atmospheric Administration have developed a radio telescope array which observes radio stars and upper atmosphere discontinuities simultaneously.

Moreover, the instrument is so economical, with a hardware cost of approximately $1000, that it should bring important new radio astronomical and ionospheric studies within the reach of universities and private researchers, large and small.

The present NOAA array consists of 16 small zigzag antennas with a signal-combiner. Conceived for the purpose of studying small-scale irregularities of the ionosphere, it was designed and developed by Dr. Clifford L. Rufenach, Dr. Willard M. Cronyn and Kerry Neal, of NOAA's Space Environmental Laboratory, Boulder, Colorado.

"Radio astronomical observations at frequencies less than 100 MHz normally require huge antenna arrays," Rufenach said. "The prototype telescope array which we built allows us to examine the ionosphere at many different radio frequencies simultaneously."

The new NOAA radio telescope design represents an advance in observational flexibility. Each element is triangular in shape with a wire zigzagging from the narrow top to the broad base. A radio wave coming down over the triangle is picked up by an appropriate length of the zigzag wire whose active portion is about one-third of the radio wavelength. Different wavelengths may be picked up by different lengths of wire simultaneously. The present array can receive radio wavelengths between 3 and 12 meters.

Absorbed radio energy travels up the zigzag wire of the element into a line that carries it along with the signals from the other 15 elements, into a central signal combiner that amplifies the output of the array.

Large-scale disturbances occurring in the ionosphere have long been interesting to scientists because they affect the quality and, at times, the feasibility of radio communications on earth. Such ionospheric disturbances can cause short-wave fadeout and signal distortions. A fairly regular fluctuation in the ionosphere's electron density results from atmospheric tides produced by the sun and the moon. Erratic ionospheric disturbances can be caused by meteors, solar flares, and magnetic storms.

Small-scale ionospheric irregularites are often related to the larger-scale upheavals, but the exact relationship is not always clear. These small-scale fluctuations in electron density affect trans-ionospheric radio communications from satellites to earth. This is particularly significant in the equatorial and polar regions where scintillation at super-high frequencies (1.5 to 6 GHz) are sometimes harmful to communication channels.

Defining "small-scale" as any irregularity less than about 2 kilometers in size, Rufenach says: "We wanted to look simultaneously at the various dimensions involved in small-scale irregularities. We first set out to design a small scale prototype radio telescope. Our initial observations with this 16-element array have been very promising."

The prototype radio telescope is located in the mountains behind the front range of the Colorado Rockies to avoid radio and television interference.

The broad-band multi-frequency radio telescope also offers a technique that should find future applications in solar radio astronomy and interplanetary scintillation studies.

73 HILTON?

Lee Wilkinson WA4QXC, was the first guest at the new motel in Tennessee. Each room has independent beam antennas, a full kilowatt on each band, and long-term guests can use FM hand held units while visiting. Stop by for a visit but keep your cameras ready; we move fast.

RED CROSS TEST

The Elkhart Red Cross ARC held an emergency test of its communication facilities on March 26. Making use of the K9HDH club repeater, several mobiles were directed to special assignments while base stations were on handy call via 94 direct to relay messages to hf nets. The emergency center was a specially prepared trailer that the club set up for Field Day, 1971. W9FJA and WA9WYY coordinated the projects. Participants were mobiles K9SRI, K9ADF, WB9BFU, WA8CEN, K9FUP; bases WA9RNT, K9FAP; headquarters K9IXB.

WA9WYY in communications trailer during emergency test.

W9FJA keeping track of mobile's location during emergency test.

GOOD NEIGHBOR HAMS

Here are the hams who founded the SIRA (Sociedad Internacional de Radio Aficionados) on Dec. 4, 1971, in Miami, Florida. They also elected a provisional Board in order to elaborate the Articles and By-laws. Seated left to right are: WN4VQH Orlando Martin, Treasurer; HK3CJD German Ordonez, Delegate; HK3CAB Hernan Melo, Secretary; WA4ZZG Rafael M. Estevez, President; WB4TED Tony Urbizu, Delegate; and HC2IP Hector Patino, Delegate. Standing left to right: CO2AB Genaro Rguez., WN4PXA Marta Estevez, CO2VE Publio Maldonado, WB4SNC Alberto Coya, SWL Edgar Bueno, YN1AEO Adrian Espinosa, CO5TM Tomas Munoz, WB4JSS Mike Caruncho, CO3JR Raul Fdez., WN4VSX Eduardo Glez., WN4UIL Jorge Quintero, K4CAG Carlos Hdez. and TG9MP Rene Alvarez. Picture taken by HP1FH Fernando Henrique. The SIRA welcomes any radio amateur who wishes to join their Society. Mailing address is SIRA, P.O. Box 71, Miami International Airport, Miami FL 33148.

Here is a partial group of Latin and American hams who attended the Annual Luncheon. They usually meet and lunch the last Sunday of the year since 1968. There were 64 persons at the last one. Hams from VE3, CO2-3, 8, YV5, HI8, HC2, HK3, TI2, W3, W4, KP4, YN1, LU3 and TG9 were at the luncheon. Picture was taken by WB4SNC. Release by Rafael M. Estevez WA4ZZG, P.O. Box 2442, Hialeah FL 33012.

STANDARD COMMUNICATIONS IS OKAY!

The instruction booklet that comes with the new SR-C146 transceivers is the first that we have seen which recommends the use of 146.52 for simplex operation . . . hooray! It did not cool our enthusiasm to see 73 and several 73 books given as prime refer ences on using FM.

73 AGAIN

Readers will no doubt be whelmed to hear that a "quiet" snowmobile engine has been announced by the Outboard Marine Corp. This dandy has a sound output of "only" 73 dB at 50 feet distance when running full throttle. Isn't that somewhere in the range of sound that can cause permanent damage to the ear? *(Thanks to K9MGX)*

WARNING!

Word comes in, certain unscrupulous antique dealers are pawning off fake radios to the public.

The new wave of interest in old battery sets generated by erroneous publicity in various publications has prompted these characters to doctor up old junkers with anything handy: rheostats replacing holes where once was mounted a variable condenser, dials and hardware from other brands, modern tube sockets for UV, unseasoned wooden breadboards and cabinets, steamed off stickers re-glued, replaced nameplates and other amateurish attempts to sell a "rare" old battery set!

Reprinted from the Old Timer's Bulletin.

TVI ESCALATION

Reprinted from the Pack Rat's Cheese Bits

The following is extracted from a complaint filed in Common Pleas Court of Philadelphia against one of our club members.

For a period in excess of three years, defendants have systematically harassed and persecuted plaintiffs without reasonable cause or justification as follows:

Since 1966 defendant has operated a wireless radio set at his residence which interfered with the picture and voice on plaintiff's television set. Plaintiff's complaints over this interference with their quiet enjoyment of the television set in their home has caused defendants to engage in a course of conduct, vilification and harassment, intended to cause plaintiffs to move from their residence.

Since 1966 defendant has engaged in the unlicensed and unauthorized sale and repair of wireless radio receivers and television sets at his residence, thereby causing the common driveway to be filled with automobiles so that plaintiffs were denied the right of entrance and departure.

In the summer of 1966, attempted to enter plaintiff's residence and claims to have authority under F.C.C. regulations to search their residence to remove the thermostat from plaintiff's refrigerator and air conditio ner because they interfered with the reception of his wireless radio sets.

Defendant often takes pictures of plaintiffs with a camera to confuse, intimidate and harass them. Since this time defendants have cursed plaintiffs on many occasions and addressed loud and abusive language and threats at them.

Since 1966, defendants have constantly and repeatedly banged on the party wall of their home, slammed the door, as well as banged on piano keys, thereby interfering with plaintiff's quiet enjoyment of their home.

Since 1968, defendants have called plaintiffs foul and vile names on many occasions.

In the fall of 1966, defendant attempted to strike plaintiff Josephine with a motor vehicle on several occasions. Defendant attempted to push a baby coach into a collision with a motor vehicle being operated by plaintiff John

Every summer since 1966, defendants repeatedly and constantly hosed the common pavement from the front doors to the street with great and excessive amounts of water causing plaintiffs to get their shoes wet in order to leave or return to their home.

Since 1966, whenever defendants dumped the water from their portable swimming pool, they would cause the water to flood plaintiff's lawn.

Defendants teased and harassed plaintiff's father (now deceased) whenever he was outside tending to the lawn or shrubbery by siccing their dog on him and by calling him names.

Since 1966, defendants constantly honk the horn of their car to harass plaintiffs. They operate their car at great speed and screech to a halt in front of plaintiff's home and blow the horn loudly and repeatedly. They follow plaintiffs in their auto whenever plaintiffs leave their home.

On Sunday, July 6, 1969, defendants had a lawn party wherein defendants and their guests amused themselves by throwing firecrackers at and against plaintiff's residence, thereby interfering with plaintiff's quiet enjoyment of their home and causing them to become fearful and apprehensive. On this occasion, the defendants said "I wish this was a bomb." One of the defendant's guests said "I wish they would come out. I could take care of them and make it look like an accident."

Defendants have often expressed their intention and desire to frame plaintiffs and have them arrested. In July 1969 defendants falsely accused plaintiffs of having stolen their cat and caused a policeman to search their home and garage for the cat.

Defendants operate an electric gasoline generator in their garage which emits noxious fumes which seep into plaintiff's home.

All of the above specified actions of the defendants have caused plaintiffs to become nervous, upset and ill, to lose sleep and peace of mind, to spend substantial sums of money for counsel fees, all without reasonable and probable cause.

Wherefore, plaintiffs bring this action in the nature of a Bill of Peace and pray the Court to:

a. Enjoin defendants from further harassment or persecution of the plaintiffs, from trespassing upon or damaging plaintiff's property and from threatening or assaulting plaintiffs.

b. Direct that defendants pay the costs of this suit.

c. Grant such other relief as may appear proper to the Court under the circumstances.

You see what a TVI complaint can lead to. After you finish laughing about the charges, consider several things:

1. An attorney will have to be retained to defend the suit (approximately $1500).

2. It could have been you.

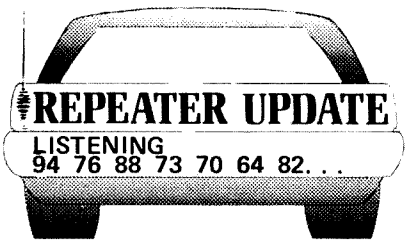
K3JJZ

TECHNICAL AID GROUP

The Technical Aid Group is a band of volunteers who offer their services to those who are befuddled with troubles. When making a request, please use an SASE. For more members with their speciality areas and information on joining the TAG, see March '72 *73.

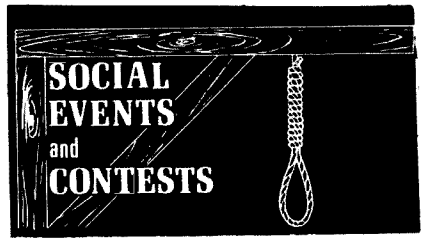
Allen Hochstetler, WA4HNX, 1524 Valencia St., Clearwater FL 33516. Allen is able to help anyone with HF transmitter and receiver problems, solid state matters, and ICs. Allen is also able to locate needed parts.

Please do not forget to include an SASE when writing to TAG members, as they are strictly volunteers and it is not fair to make them spend lots of postage money when they answer lots of questions.



In Memorium — James R. Lightfoot, WA1KRN

Word was received on ECARS March 20th of the sudden passing of one of the founders of ECARS, Jim Lightfoot. Jim had a massive coronary attack at the age of 35. He will be missed greatly by all his friends. Jim, along with the late K1LTO and WA3GAL, was one of the original triumvirate that got ECARS started one wintry day a few years back.



The press of his job as general manager of WBZ in Boston became too great to continue editing and publishing the ECARS Monitor as well as maintaining all the ECARS membership records. He did continue printing and mailing the Monitor. It was only when WA1KRN became President of Firestone Communications and moved to the New York City area that he had to sever fully his working connections with the service, but he continued to be as active as possible on the air and to support the service in every way possible.

Jim just recently moved to San Diego to take over a broadcast station there, and it was in California that he passed away.

FM WEST, the First Annual Western Amateur FM Conference, will be held in conjunction with the California Amateur Relay Council meeting on June 2–3. Friday night's champagne party and the Saturday technical talks and exhibits guarantee an excellent program. Saturday's banquet, a scrumptious affair, will be followed by door prize announcements and individual repeater movies and talks. The conference will be held at the Tropicana Lodge, 4061 N. Blackstone, Fresno. Motel reservations must be made before May 20, and specify you are attending FM West. Contact WB6OSH for more information.

CALIFORNIA FM SCENE

Bob Greenberg WB6INR/6

The FM scene in Los Angeles has gained a certain degree of infamy, due to the rapid, unorganized growth of FM in the last few years. It is well known that the Southern California area has had numerous problems with desensitization, simultaneous frequency use by different modes, intermodulation, etc.

According to a survey done in November, 1971, by Jack WA6JXG, there are at present the following repeaters in L.A.: 4 open FM, 3 closed FM, 2 AM, 1 RTTY, plus an additional 8 others proposed (plus innumerable remote base stations). There are also 10 open FM repeaters and 3 proposed within a 150 mile radius of L.A.

Of the 20 operating repeaters in Southern California, only two are on standard 600 kHz spacing and standard channels. All the others are on channel pairs that most likely are unique to this area.

There are rumors of a Repeater Owner's Council of some sort being formed, but at present, no such organization exists. It should be pointed out that if we don't organize soon, there will be at least eleven other repeaters to consider in the near future.

Interesting activities have been occurring on WB6ZDI, the Palisades Amateur Radio Club's Repeater. The PARC Repeater operates on 146.61 in, 147.33 out, and has approximately 300 hams populating it. Apparently this concentration of hams attracted the FCC to monitor ZDI since in the past few weeks there have been several citations handed out for improper identification (not signing the call, area, i.e. 76) and out of band operation. The latter was the secondary violation in both cases so far, with Technician class licensees being repeated out of their band segment. At present, the FCC has not replied to the cited amateurs' letters. Each one simply stated they were only transmitting in their assigned band, on 146.61 MHz. Has anything similar happened in other parts of the country? More on this next time.

Information about the rest of the West Coast has been non-existent so far, and contributions would be welcomed. Please mail them to Bob Greenberg, 16705 Dalton Ave., Gardena, CA 90247.

Circle June 10th and 11th on your calendar. The Atlanta Amateur Radio Club will hold its annual hamfest on the Mall at the Lenox Square Shopping Center. A banquet will be held Saturday night, June 10th. Main prizes include your choice of a Drake TR-4 transceiver with AC Supply or a RCA Home Stereo Center. A Regency HR-2A will also be given along with other fine prizes. Experts on Teletype, FM, DX and many other subjects will be present. For further information contact W4JM, James Gundry, 2498 Echo Drive, N.E., Atlanta, Georgia, 30345.

* * *

The Tri-State Amateur Radio Association will have its 10th annual hamfest at Camden Park, Huntington, West Virginia, June 4, 1972 from 11 A.M. to 4 P.M. Activities: CW Contest, QSL bulletin board, flea market, prizes for the oldest ham, the youngest ham, and the "fartherest-away" ham. Drawings for the major prizes will be at 4 P.M. featuring Drake TR4 and Drake TR22. You do not have to be present to win major prizes. Tickets are $1.25 each or 5 for $5.00, available from Tri-State Amateur Radio Association, P.O. Box 1295, Huntington, West Virginia 25715.

* * *

The 1972 Jackson Amateur Radio Club hamfest will be held July 29 and 30, 1972. All events will be held inside the Heidelburg Hotel in downtown Jackson MS. The banquet begins at 7:30 P.M. on Sunday, July 29. The price will be $6 per person. The hamfest begins at 8:30 A.M. Sunday, July 30, in the Victory Room. A TEMPO I with ac supply is the first prize. Write to Charles Rogers WA6FII, P.O. Box 8371, Jackson MS 39204 for more information.

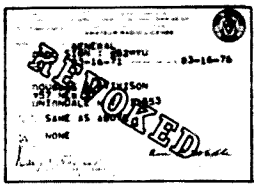
MASSACHUSETTS AMATEUR RADIO WEEK

Operating times are from 0001 GMT June 11 to 2400 GMT on June 17. Massachusetts amateurs must work 16 other Mass. amateurs. The rest of New England State amateurs must work 8 Mass. amateurs. All other amateurs in the U.S. must work 5 Mass. amateurs. DX, including KL & KH must work 2 Mass. amateurs. Any band and mode may be used. All stations participating will exchange signal report, County, and State. Logs must show date, time, and frequency of contact. Applicants must include a No. 10 size (business size) self-addressed stamped envelope (DX enclose one IRC) with application which must be received no later than July 31, 1972. Submit applications to William Holliday, WA1EZA, 22 Trudy Terrace, Canton MA 02021.

The Music City Hamfest will be presented by the Nashville (TN) ARC June 18 (Father's Day) at Lock Two Park, two miles north of Opryland USA. Flea market, refreshments and more. Prize drawing will be held at 1:30 P.M. Talk-in call is K4CPO on 75m and FM 146.94. For more information write Music City Hamfest, P.O. Box 8085, Nashville TN 37207.

* * *

The Ninth Annual Penn - Central Hamfest will be held by the Milton and Williamsport clubs on Sunday, June 4th, starting at 12:00 noon at the Union Township Volunteer Fire Grounds on Route 15 in Winfield PA. Bring your own lunch or use the snack bar. There are indoor and outdoor facilities for auction, contest, and swapping. Gate registration is $2.50 (XYL and children free) and parking is free. Talk-in frequencies: 3940, 50.4, 146.940 2 meter FM. For more information, write to Paul Mitch W3LXN, RD 2, Milton PA 17847.



* * *

AKRON, OHIO – The Goodyear Amateur Radio Club will hold its 5th Annual Hamfest Picnic on June 18 at Goodyear Wingfoot Lake Park east of Akron, 1 mile west of Suffield, Ohio on County Rd 87 near Ohio Rte 43 Entertainment, swap-and-shop, prize awards, and good fellowship. Refreshments, displays, huge flea market. Hours: 10 A.M. to 6 P.M. Family admission $2 prepaid, $2.50 at gate. For details, tickets and map write Eugene J. Cooke K8ORL, 3079 Rosebay Blvd., Norton OH 44203.

* * *

The Kansas Nebraska Radio Club will hold its annual hamfest on August 6 at the Moose Club at Concordia, Kansas. Registration will start at 0900. All amateurs are welcome.

WITH THE FCC

The following FCC Bulletin appeared in Florida Skip.

Federal Communications Commission
Field Engineering Bureau
Bulletin

"Manufacturers of audio devices for home use do not design such equipment to operate in the presence of strong radio signals from nearby radio or shortwave stations. Strong radio signals which cause interference to audio devices require that special treatment be given to the audio device receiving the interference. The Commission cannot give any protection to audio devices from interfering signals. The only 'cure' is by treatment of the audio device receiving the interference.

"You should, therefore, contact the dealer or manufacturer of your audio device (or telephone company for telephone interference) for assistance. The state of the electronics art is such that it is possible to manufacture 'custom built' audio devices; that is, to install in the complete shielding and special circuits to reject nearly all types of unwanted signals. Cost of such special design and circuitry would necessitate an increase in the price of the devices.

"Perhaps less than one percent of the total number audio devices in operation todaywill ever be located near enough to any kind of radio station so that the device would respond to undesired radio signals, which it is not designed to receive when in the strong field of a nearby station. If it does, it needs additional filtering or shielding, or both. Manufacturers believe it unfair to burden an entire population with the additional cost of special circuits and design inasmuch as the number of devices affected is small. Therefore, in the less than one percent of the instances where interference is caused by insufficient rejection of strong unwanted signals by the devices, many manufacturers, dealers and servicemen have worked out procedures and processes for interference elimination in such specific cases. The statement of a salesman or dealer that he sells a good quality device, is not enough. Persons receiving interference must fully recognize the situation involved. The audio device may be an excellent one in performing the task it was designed to do. Regardless of the quality of the device, special treatment of it for rejection of strong unwanted signals is essential in some localities.

"RF interference to transistorized audio amplifiers can be eliminated in most cases by connecting capacitors or both capacitors and RF chokes directly from base to ground of the input transistor. If the audio amplifier is part of a stereo system, then this has to be done on both channels. In interference cases of this nature the volume control is in the input circuit, consequently, it has no effect on the RF interference."

ERRATUM

Mr. A Prose Walker has advised us that several of the figures in his speech (reported last month on pages 85 through 89) were incorrect. On page 86, the path losses should have been approximately 176 dB at 435 MHz and 166 dB at 146 MHz. Thus the system in the example would have less capacity and/or signal to noise ratio than indicated. However, various combinations of ground to satellite equipment characteristics can be assumed, each giving different capabilities for an overall system design. Needless to say, the example used was not intended to be used in a hardware proposal for a system.

EDITORIAL BY WAYNE GREEN

DAYTON!

The Hamvention is hands down the biggest ham event of the year. The only real criticism I can make of it is that it should run for two or three days instead of one single day. There is just too much to do.

If you have any interest in building or buying equipment then you can't pass up the flea market. I would estimate that there were a couple of hundred "booths" set up in the parking lot with enormous piles of ham gear . . . from the most sophisticated slow scan and FM gear right on back to World War I military surplus. Tons upon tons of parts . . . equipment . . . stuff. They had more there than the Allied catalog. I spent an hour browsing through the place and wished I had several more hours and a pickup truck . . . plus unlimited cash.

The manufacturers' exhibits were lavish. There was no way to see them in less than a couple of hours . . . and to do that you would have to skip a lot of interesting things. Many new items were being shown there for the first time. Tom Litty K6RAD had a TPL Communications booth and showed his new 220 MHz transceiver which should be out in July in quantity, selling for about $220. He also had his superb line of solid state amplifiers for 146 MHz, 220 MHz and 450 MHz. These items are being merchandised by Henry Radio under the name of Tempo and are built in California.

Ed Clegg was there with his new 220 transceiver, also due out in July in production runs. FMers also looked longingly at the 27A Clegg unit on display. Drake surprised everyone with their new 220 transceiver, made by the same folks who make the Marker Luxury 2m rig.

There were so many new things that there is no way to remember all of them. J&R Electronics were showing their new slow scan monitor . . . should be a winner. Robot was wowing them with their slow scan gear and showing what can be done. Slow scan was really big at Dayton . . . it looked like about 500 active slow scanners at the forum to me . . . and the orders for our upcoming slow scan book poured in.

The forums ran all day long and I wanted to see and hear every one of them . . . but had to miss virtually all since I had to stop by the 73 booth now and then . . . see the other exhibits . . . try and sell a few ads (almost impossible in the hubbub) . . . and put in a few words for several of the forums when I managed to get to them at an appropriate time. I tried to make the Midcars forum, but got there early and late . . . I wanted to try and let them know that I intended to convince repeater groups to set up a down link to 7255 kHz for emergencies so the two meter repeaters could work 7255 simplex when wider area emergency coverage is needed. I just got one of the little Justin sideband transceivers and hope to have a chance to set it up with our repeater (WA1KGO) for this service, operated by a 2300 Hz tone burst to make the down link tie in.

I had my slides of Jordan along, but didn't see myself on the program so I wasn't sure when to drop in on the DX forum . . . they seemed busy when I went by . . . and I missed showing them. Oh well, I'll have a new set of slides of Jordan in a few weeks My others are two years old now. Time flies.

Some of the companies that didn't turn up as exhibitors were interesting for their absence. There has been some mystery about whether Rpt magazine was still in business or not. The last issue I've seen or heard about was February. They didn't show at Dayton . . . but a good friend of mine did show there sporting a disk jockey magazine just being started by the erstwhile publisher of Rpt . . . and he said that Rpt was on ice. I think I mentioned that special interest ham magazines have a way of never making it.

There was no Dycomm exhibit either! When you consider that this was the biggest FM event in the country this seems very significant. Incidentally, 73 will no longer accept advertising from Dycomm.

Judging from the number of Motorola HT-220's I saw at Dayton, the Motorola company must have added at least one more assembly line. It looked like thousands of the little beasties, though it probably wasn't any more than 500 or so. They were in pockets and hanging from belts everywhere. The Standard 146 is beginning to show now too . . . I did see dozens of them. They're just getting started. Oh, by the way, watch out for the Standard 145 . . . this is the Japanese model and is startlingly different from the 146 . . . different transmitter in particular. It uses 12 MHz crystals, in case anyone tries to fool you. The 146 uses 8 MHz crystals, like the 826. We had a 145 here at 73 for a few days and were unable to tweak it on channel because the rig had so many outputs that the counter couldn't decide which was the one to count. I don't see any way that unit can meet FCC specifications. I guess they don't care about spurious output that is almost as strong as the intended output in Japan. We care. Beware.

MIDWEST FM SYMPOSIUM

On the evening before the Dayton Hamvention a special FM Symposium was held at the Imperial Motel. Though there was little time to pass the word about the meeting, representatives of 46 midwestern repeaters were present, along with about 300 FMers.

The main topic for the evening was the plans for organizing a serious effort to save the 220 MHz band from the EIA and a handful of greedy manufacturers. The main approach to holding the band is to use it . . . "USE IT OR LOSE IT."

This Symposium was a follow-up on the one in Shrewbury (Mass.) in February where representatives of over 50 eastern repeater associations agreed to set up 220 MHz repeaters as soon as practically possible. Within days of that meeting the first 220 repeaters were set up and operating, coordinated by F2BO/W1, K4GGI/1 and WA1KEC the committee for eastern U.S. coordination.

The repeater representatives at Dayton also agreed 100% to get on 220 as soon as possible. This leaves only the southwestern and western parts of the country still not committed to going 220 immediately. Hopefully the repeater groups in these areas will get together at Fresno in June and put their repeaters on the line to back the project to save 220. California needs 220 more than any other part of the country, so perhaps this will be an added inducement.

Considerable equipment is coming along for 220. Ed Clegg showed his new 220 transceiver at the Symposium. This unit has a great many interesting features and should be in production by July and sell for under $300.

Bob Booth W3PS, counsel for the ARRL, was present and spoke about the need for cooperation between all groups if the band is to be saved. Both ARRL and 73 are working for the

same goals and working in the same directions . . . now if only CQ and Ham Radio would lend a hand!

The Midwestern Symposium was certainly fun . . . and a success.

73 PROTECTS YOU

Some of the FM units that we have checked out have not been written up in 73 . . . and this is no accident. They just don't pass muster. When we run into rigs that are not up to snuff we not only refuse to run articles on them, but we generally refuse to accept ads for them, unless the problems are marginal. You may be sure that when we do write about a rig that we have checked it and we like it.

A reader recently wrote in regarding one of the transceivers that 73 has NOT advertised. *"Have had much trouble. The receiver desensed 100% by nearby low power transmitter. Factory installed trap cured that problem. Intermod tremendous. Local taxi and sheriff's repeater cause full scale deflection of signal strength meter, local 2m repeater desenses receiver. Sensitivity changes with vibration. Squelch much too touchy; meter impossible to read at night in the car; insufficient audio for mobile operation; channel numbers difficult to read; cover screws strip easily; etc."* This chap has a Sonar 2301 that he likes and a Standard 146 he thinks is "great." From all those desensing problems you might expect this chap to be in New York City . . . he is in Nevada.

WHOM TO WRITE

If you are uptight over the idea of turning our desperately needed 220 MHz band into a screaming mess of CBers . . . if I may put the case to you factually and unemotionally . . . then why not drop a line giving your thoughts to one or two of the members of the Electronics Industries Association Executive Commitee?

You might write to the Chairman of the Executive Committee, Richard Horner, E. F. Johnson Company, Waseca MN 56093. Or you might get in touch with Andy Andros, the president of Hy-Gain Electronics. Lincoln NB68501. If they can't stop the drive to take away this band, at least they can pull their company out of the EIA and stop furnishing the money which is being used to lobby for it in Washington.

CONTROVERSIAL FM'ER

The other day Carl Lindeman W1MLM, NBC's VP of sports, was flying across the country, TR-22 in hand, talking through various repeaters. With him was controversial sportswriter Howard Cosell. Howard's interest in the proceedings quickly rose to where he spent most of the trip arguing heatedly with amateur radio sports fans as they passed over them.

I can just see a dozen or so amateurs across the country rushing into the kitchen and telling their wives . . . "Hey, I just talked with Howard Cosell!" And I know what the wives said, too. "Who's he?" Fellows, I know just how it feels. A few weeks ago King Hussein called me on 20m and we talked for a while. After I signed I was busting to tell someone about it and at that particular time the baby sitter arrived so I casually mentioned to her that I had just finished talking with King Hussein. She had never heard of him . . . or Jordan. I'm not sure she has ever heard of Israel.

K2ORS NOMINATED!

Jean Sheperd K2ORS, frequently heard through the repeaters around New York . . . particularly WA2SUR . . . via his Tempo FMP transceiver, and heard nightly through WOR, has been nominated for an Emmy award this year. Jean Shepherd and Jane Fonda were the nominees for the Most Interesting New Performer on television for 1971. If you have any friends whose vote counts toward the Emmy, nudge them re Shep.

Shep was the feature speaker at the FM Symposium in Shrewsbury in February. The array of walkie talkies there got to him, and he has been an active FMer ever since, usually talking from his office high up in the WOR building on Broadway.

MORE TWO METER FM CHANNELS

The FCC does not have any intention of giving us the green light for repeating Techs above 147 MHz. Though their rules are quite explicit and it would be exceedingly difficult to interpret them as prohibiting a repeater from retransmitting Techs above 147, it is obviously easier to avoid a fight than to go after one . . . so most repeaters have been avoiding the 147 MHz range.

The 146–147 segment is FULL in many parts of the country and the pressure is mounting for more FM repeater channels. Where to go? Once gear is available in quantity for 220 MHz that is the obvious band for further repeater expansion . . . but it will be quite a while before the manufacturers are able to supply us with enough 220 gear to make that band really useful for everyone. In the meantime we must have more FM channels . . . and they must be on two meters. The answer is obvious . . . they will have to come out of the 145–146 MHz segment.

But won't we get into a big fight with the AM ops down there? We started in above 146 MHz because the AMers didn't use that part of the band. If we start moving down aren't we liable to get a big war started? I doubt it.

I've been tuning the lower two MHz of the band for some months now and I have so far heard exactly one (1) AM station on the 2m band from up around the New Hampshire area. One weekend I tuned the band in New York and all I heard there was one (1) AM station all weekend! Either I managed to listen at all the wrong times and missed hearing all the AM activity or else all those chaps have moved up into the FM band. I suspect the latter. Who would stick with AM on 2m when FM is so very much better?

If my survey is correct, then we do have some channels available for FM which will not inconvenience any other ops. I suggest that instead of using those confounded splinter channels in the 146 range that we start using standard channels in the 145 segment.

If we start easily, opening up about six FM repeater channels, there should be a minimum of bloodshed. I suggest that the repeater input be high and the output low, with the following channels used.

145.71 - 145.11	145.80 - 145.20
145.74 - 145.14	145.83 - 145.23
145.77 - 145.17	145.86 - 145.26

This system will leave the bottom 100 kHz of the band open for AM operation . . . sideband, whatever. It will also leave the surplus crystal channel of 145.35 open . . . as well as the 145.9 146.0 for satellite input.

I realize that this is probably impractical in Los Angeles, but perhaps it will work elsewhere. Any comments? Any takers?

600 kHz Uber Alles

The universal change in the eastern part of the country to 600 kHz repeater spacing was not accomplished without some difficulties. The wonder of it was that the battles were so few and far between.

Some of the skirmishes have recently been settled. For instance there was the little matter of WA1KFX on Mt. Snow on 31–91. This repeater, operated by Gordon Pugh W2GHR, had been on 31–88 for some years and then suddenly appeared on 31–91 early this spring . . . not long after the Mt. Greylock repeater shifted from 04–91 to 31–91. Thus there were two closely spaced and far-reaching repeaters both on 31–91. The result was an incredible mess and the hardest of hard feelings.

Many repeater people have been severely critical of Pugh for jamming

(continued on page 10)

W2NSD/1 *continued*

the Greylock repeater and have been openly hostile to the attempts of Pugh to form a repeater organization in view of his lack of cooperation on 31–91. Pugh was the instigator of the North East Repeater Association and became its first president.

Apparently the pressures grew to where something had to give . . . and Pugh gave. WA1KFX would go off 31–91 and would move to some other open channel, possibly 01–61, since that seemed open for that area.

It should be pointed out that WA1KFX, though it has been on the air for several years, is remotely enough located in Vermont so it has seen little use. It has been off the air entirely for the last few months, so the sudden appearance on 31–91 was quite a shock to the K1FFK groups, which number close to 200.

KFX is reachable in April only on skis and the first reports are that Pugh did follow through with his agreement to turn off the repeater, but that he broke a leg on his way back down the mountain. The Greylock group wishes him a speedy recovery.

Another hassle was over 146.76 around the Long Island–Connecticut area, with WA2UZE on 16–76 and Bridgeport WA1KGK on 22–76. Power and feelings had escalated about evenly and the grievances were many and strong . . . UZE was there first by about ten years . . . KGK had more users and a wider range . . . and so it went. The solution came when the two principles finally sat down at the bargaining table and worked it out. UZE would stay on 76 . . . KGK would move to 10–70 . . . the UZE crew would guarantee to move heaven and earth to get the RTTY ops on Long Island to change from 70 to 146.55 as an RTTY simplex channel . . . and this is not simple because it means coming up against Byron Kretzman W2JTP and occupying his "private" channel. The Staten Island group agreed to move WA2YZZ off 70 RTTY to make room for KGK . . . and so it went. K1ABR in Rhode Island will probably move from 10–70 to 01–61, thus giving KGK more elbow room.

One other sore point was solved too, with the WA3BKO Philadelphia group agreeing to get the higher powered base stations to stop using 28 and use the 16–76 Philly machine, thus permitting WA2YYQ on Staten Island to move from 25–88 to 28–88.

Things are really falling into place for universal eastern 600 kHz spacing.

. . . *Wayne*

Military Affiliate Radio System

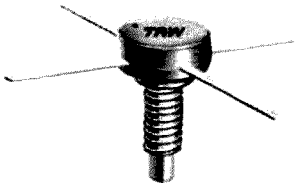
New Chief MARS Army, A3ZLH, is off from the starting gate faster than a speeding bullet! Innovations already announced are plans for updating the weekly WAR Broadcasts, a new SIG 439-2 Communications Manual and new carpets for the office! Chee! Southern New England has a new RATT net on 4035 kHz at 1901Z Sundays. A3NFS won the First Army Commander's Annual MARS Trophy. A1VFB is new Maine Army Mars Director. MARS Director. A very well-attended Spring meeting was held at Natick, Mass. As most such meetings, it included a "happy hour." Fifth Army MARS called it by a different name at their four-state convention in Fort Leavenworth, Kansas – "Attitude Adjustment Hour!"

Delaware MARS held their semi-annual meeting in Dover, complete with Crab Imperial, Crepes Suzette and a Swap-Shop. Their first two meter repeater should be in operation soon (in 148.01, out 143.99– as are most MARS Army installations). A *"did you know"* item: Office of Civil Defense has hired Systems Development Corp. to make a study of RACES. Wonder whom they will ask for opinions? Armed Forces Day cross-band operation was greater than ever, with NSS, NPG, AIR and WAR reporting hundreds of contacts with hams throughout the world. Your QSL cards and certificates will be mailed soon.

Air Force MARS is undergoing a geographical reorganization. Details have not been officially announced, but a reliable source informs us that there will be three major divisions, each being divided into several smaller groups of states. The new Air Force MARS manual is being distributed and one important change is noted: AF stations are now allowed to cross state lines with VHF repeaters as long as operation is within the same region.

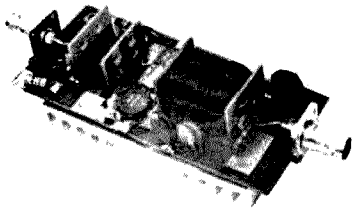
Third Army's Fifteenth Annual MARS Conference was attended by more than 700 members and guests! They too had an "Attitude Adjustment Hour," a portion of the activities which can only increase in popularity as time progresses. Congratulations to Director Hal Mulkey for the finest conference ever. Assistant Chief MARS Army Joe Ziglinski was a welcome guest. Congratulations to AD4DQQ, honored at the Conference as Third Army's Operator of the month. In passing, Third Army's oldest VHF repeater, on Brasstown Bald is now in its *13th year!* This repeater was utilized to bring immediate help during a recent tragic occurrence. A camper-trailer went through a guard rail into Lake Hartwell in South Carolina. A4AZT, witnessing the accident, called through the repeater into Atlanta reaching AA4YBT, who alerted the South Carolina Highway Patrol. Although help arrived within a matter of minutes, it was too late.

Fifth Army Director Roland Belk has been on the road for months attending State meetings throughout the area. One of the largest was the Texas meeting at San Antonio. Still upcoming: Iowa, 3–4 June, Minnesota 8–9 July and Illinois on 31 July–1 August. ADØNIC was named Fifth Army Operator of the month, and AA5WHN is new Training Officer of Fifth Army. New Manual REG. 105-4, is being distributed to members.



The Texas RATT Net has gone to 170 Hz shift – a growing national trend. If you have been using WBR/70, Miami WX, to adjust your printer, etc., don't be surprised when they go to 100 wpm on 1 July. Louisiana has a new VHF emergency communication plan, under which the 2 and 6 meter MARS repeaters are tied together to cover a large part of their area. Meetings in that state were held in Shreveport and Alexandria. Missouri State MARS meeting is being held in Lebanon, with VHF repeaters high on the agenda. A new Missouri repeater is in operation in the Cape Giradeau area – your editor accesses it often, but perhaps they don't answer AR's.

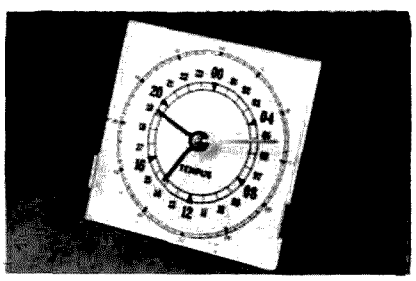
AA6TOV has been appointed Director of Research & Development, Southern California Army MARS. That group's very fine Monthly Signal, edited by AA6GJY, has just finished a fine series on the Apollo program, and is now featuring a first-person account of the sinking of the USS Milwaukee in 1917, a story told by AA6LJ. In addition to the usual 148.01–143.99 repeaters, the Southern California group has repeaters on 143.415 in, 148.650 out. Also, while we are fooling around with those 2 meter frequencies, they already have nets going on 432 and 1296 MHz! The Arizona MARS meeting will be held in Tucson in conjunction with the Old Pueblo Radio Club Hamfest.



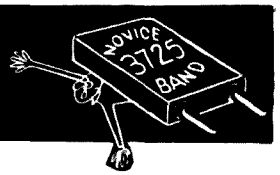
This column is designed to keep you informed of matters MARS. If you have information that should be included, or if you would like to become a member of one of the three MARS programs, contact Harry Simpson, A4SCF, P.O. Box 27015, Memphis TN 38127. ZKJ – which is MARS-ese for QRT.

NEW PRODUCTS

NEW LINEAR TRANSISTOR

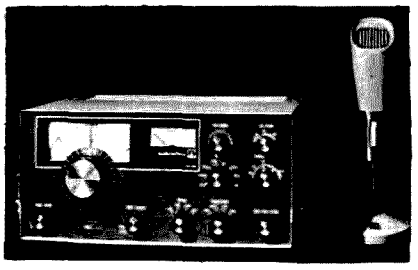


TRW Semiconductors has developed a new transistor that will have wide-reaching effect upon us all. Their PT5740 series can be driven with less than a watt for outputs of over twenty watts at twelve volts. This is significant for transistor power amplifiers that can be used in your car with flea power drivers. Four of them can be driven to over 100 watts output which is perfect for driving most tube kilowatt amplifiers currently on the market. QRPPers can easily go QRP or QRO with a single transistor.



There are simple circuits that can be duplicated to make broadband power amplifiers that will amplify a one watt signal to over a hundred watts output at 14 MHz, all from a 12.5V dc source, not 28 volts as is required on several other similar circuits. As the amplifier is broadband, no tuning is necessary from 80 through 10 meters with a 50Ω load. TRW has the transistors available, and their application notes give all the information needed to make the power amplifiers. Write to *TRW Semiconductors, 14520 Aviation Blvd., Lawndale CA 90260* and ask for CT-122-71 and CT-113-71.

CORDLESS 24 HOUR CLOCK



Traffic men and DXers who need to watch the time in two time zones will want to buy this 24 hour clock with a second hour hand for keeping time in local time, Greenwich time, EST, EDT, or any other time. The beauty of this clock is that it will run for almost two years on a standard C-size flashlight battery. This handsome clock will look beautiful in your shack and it will help you meet your nets and skeds. It is only $29.50 from *Tempus Instruments, Villa Italia Center Suite 594, 7200 W. Alameda Ave., Denver CO 80226.*

NOVICE

Alaska is a rare state for most people, not just Novices. In fact there are only about 1,200 hams in Alaska, which is about 0.4% of the total number of hams in the entire U.S. Although it looks hopeless for the Novice to find an Alaskan ham, much less an Alaskan Novice ham, there is a way. On most week nights at about 0700 GMT, there is a Novice Net that is based in Alaska on 21.225 MHz. Active stations in the net include WL7HH), WL7HET, and WL7HJR. Although it may seem unlikely that you might get in to Alaska at that hour, keep listening. This is the kind of activity for which many top DXers look. Tune the frequency at the time that the station is normally on, and keep doing this until the moment comes that you work the rare one. He may be booming in due to freak conditions or he may be very weak in the noise. But keep trying. He's in there waiting for you.

NEW SSB/CW XCVR

Hallicrafters has a new sideband transceiver that deserves investigation if you're looking for a new or second rig. The FPM-300 features all solid-state construction with only two tubes and modular construction throughout. The rig runs a cool 250 watts PEP or 180 watts CW. You will sound much stronger on sideband, however, because there is an IC speech compressor for emphasizing audio punch. Full coverage of all bands and built-in ac and dc power supplies complement the rig for a great fixed or mobile signal. *Hallicrafters Co., 600 Hicks Rd., Rolling Meadows IL 60008.*

AMSAT ACTIVITIES

Mike Frye WB8LBP
640 Dauville Dr.
Dayton OH 45429

The Radio Amateur Satellite Corporation (AMSAT) was formed in 1969 to provide amateur satellites and space experiments for the amateur service. Membership currently numbers 460, including over 40 member societies, and is worldwide with amateurs from some thirty countries represented.

AMSAT is currently active in preparing for the launch of AMSAT-OSCAR-C (A-O-C), scheduled to go up in July, 1972. A-O-C will feature a 24 channel Morse code telemetry system developed by W5CAY; the 432–146 MHz ten watt linear translator developed by DJ4ZC and DJ5KQ in Marburg, Germany; the two-ten meter linear translator built by W4RUD, WA4DGU, and K3JTE, the 35 function command system provided by WAI-Project Australis, and the instrumentation converter provided by W3GEY, A-O-C project manager. CODESTORE, a Morse message storage unit was developed for storing emergency messages, operational information on the satellite and orbital information for repeated transmission to the ground over the satellite's telemetry systems.

When A-O-C is ready for launching it will ride piggyback on NASA's ITO S-D meteorological satellite into a planned 1500 km polar orbit.

AMSAT has also submitted a proposal to NASA to provide for amateur experiments aboard the ATS-G Applications Technology Satellite scheduled for 1975. The space would be put to good use with a SYNCART (*SYN*Chronous *A*mateur *R*adio *T*ranslator) experiment. AMSAT will provide NASA with a 146–435 MHz 20 watt linear translator for integration into the ATS-G package. The satellite will be placed in a geostationary (synchronous) orbit. It will contain a 30 foot parabolic reflector which is available for the SYNCART experiment. This will enable amateurs for the first time to use a synchronous satellite on a more or less regular basis with modest amateur equipment.

The SYNCART package is designed for emergency communcations, educational training and experiments with small terminal multiple-access communications.

AMSAT members at the NASA Goddard Space flight center and many other manned flight centers have been assisting with these projects. Dr. Owen Garriott, one of the astronauts in training for SKYLAB, has indicated his support. Dr. Garriott happens to be W5LFL and a member of AMSAT.

The 50 MHz Band

As of this writing there has been no further word on the VP5RS DXpedition planned by W4GDS, but knowing Bob's ability to get things done it would be safe to assume that everything will come off as scheduled.

Webster defines a hobby as "a pursuit outside one's regular occupation enjoyed for relaxation." Public service aspects aside, amateur radio is supposed to be fun. It therefore behooves each of us to avoid doing things which deprive others of their pleasure. Do you call a rare or DX station every time he stops transmitting? Do you inquire if the frequency is in use before calling CQ or tuning up? Do you own and USE a dummy load, even on VHF? Do you make transmissions so long the band folds before you complete one schange? Do you call CQ so long the prospective contact gets tired of waiting and looks elsewhere? We have all experienced signals 20, 30 or 40 kHz wide obliterating a goodly segment of the band. A malfunction can happen to anyone, but all too often the cause is Fred talking to Harvey down the block with his Band Burner VI (or the matching linear) cranked into saturation . . . just like the last time the band was open. QRM from other stations in QSO and tuning up, etc., has become as common as on the lower bands. But it need not be so. Rarely, even during the widest openings, does one hear activity above 50.2. With 4 MHz available, doesn't it seem a bit ridiculous to congregate in the first 50 kHz? Would it not be reasonable to assume that all would profit if we were to make better use of the band during openings?

A report has been received to the effect that WA5HNK worked CE4CP on March 25th. This to my knowledge is the first Chilean contact since Urly, CE3QG, was active several years ago. XE1PY remains active with several stations reporting contacts during the past month. Bob WAØTXV, is looking for scatter and/or groundwave contacts on Sunday mornings from 0500 to 0800 CST.

The comment in the March issue relative to the lack of activity in Kentucky really stirred up a hornets' nest. Tony WA4JQS, informs us that he and Ken WB4UQC, are active from Somerset. Both are working on linears with 3–500Zs. This industrious pair will be operating from a fire tower at 1590 ft above sea level during the VHF contest and will be happy to make schedules on 3960 kHz. Also add Hamp WB4SBU and Don WA4VIR of Jeff Town and Fort Campbell to the list of active stations in Kentucky.

SSTV SCENE

Slow scan activity has started to pick up on ten meters with most of the activity centered on 28.680 MHz Saturday mornings and Sunday afternoon. A fair amount of activity from Europe and Africa there also.

A few months ago I noticed Denson Electronics' large ad in 73. So I checked into them and found a real gold mine of fast and slow scan TV goodies. Zoom lens, turrents, projection TV systems and much more. The video tape recorders really caught my eye. Some were under $400! What possibilities! Video tape those ATV QSO's, or make up programs to feed when you're not using the camera. Coupled with an on-off timer and TV, you could work up a system to tape favorite TV programs for later viewing. Our day of dreams is rapidly approaching.

Those suffering TVI would do well to try the bandpass filter design by WA5SWD/6 described in the January 1970 issue of 73. Several of these are in use in this area and are doing a good job of reducing TVI on the local channel 2, the callsign of which is a very appropriate KTVI.

Doc WA7FLB, reports a very quiet winter, which is probably just as well. Doc has had antenna difficulties but promises to be back in full operation shortly. K9SDF is recovering from double hip surgery and expects to be out of the hospital and on hand for all of the spring openings. Very good planning, Gabe! Larry Phant WØRVF, works the nightshift on 6 meters, seldom getting on before midnight. You late night types would do well to turn your beams in the general direction of St. Louis in the early morning hours.

It seems that not many 6 meter hams are aware that many TV manufacturers will supply high pass filters at no charge or for a small handling charge. I would be pleased to send a copy of a list of manufacturers' addresses collected over a period of years to anyone sending an SASE to my home address. This list is not complete in that many "house" and imported brands are not included, but it does cover a good cross-section of the more popular brands. Perhaps I am leaving myself open for more than I can handle, but I will also offer assistance to anyone who needs help in getting on the air, curing TVI, or any other problem, as long as it pertains to 50 MHz operation. I can't guarantee anything other than a sincere effort. See you on 6.

Bill Turner WAØABI
5 Chestnut Court
St. Peters MO 63376

I have a very interesting picture for the column this month. This was recorded by W7ABW, and photographed (and described to me) by WB8BQT about two years ago. Notice first the skewed lines running from the bottom left to the top right of the picture. Here the playback recorder was running slightly faster than the recording tape recorder, thus the lines "lean" toward the right. If the playback recorder had been slower than the recording recorder, the lines would be skewed from the top right to the bottom left. If the two tape recorders were running at the same speed the lines would be vertical, and not noticeable, except for four very slight "humps" at the very top of the picture. It is those four "humps" (60 cycles divided by four) that makes the skewed lines. The picture starts erratically on the right top. A perfect SSTV picture starts the first line two thirds of the way across the top. (The blank period is the vertical re-trace.) Notice the texture of the hair, and the white of the collar this is evidence of a high quality gray scale. There is a slight light reflection in the center of the left eye, showing the definition a 120 line slow scan picture is capable of producing. Now remember, a certain amount of quality is lost each time a picture is reproduce i, thus the original image on the screen was better than the photo and the photo better than the magazine picture. So the magazine picture is third rate to the original viewed on the screen.

Robot Research is busy these days. Their SSTV directory is in the works and should be available very soon. If you haven't sent them a post card yet telling of your SSTV activity better do so right away or you may get left out. They are also publishing a short SSTV newsletter which is usually available from authorized distributors. It is refreshing to see a company interested in just more than selling their product, and Robot is as gung-ho on slow scan as we are.

That fellow with the high country total on SSTV is Gene W8YEK, who has 44 countries confirmed. Close behind him is Eddie W4MS, with 40, and WAC/SSTV. W8UUS and a couple

Microwaves

Those amateurs working at the higher microwave frequencies will be glad to know that the National Bureau of Standards (Boulder CO) can now measure frequencies on the order of 85 terahertz (or 85,000 GHz) to an accuracy of about ±10 parts per billion. The apparatus used as a mixer for these measurements uses a microscopic version of the cat-whisker diode. Shades of 1923!

AT&T has proposed that the land mobile telephone service be moved from 50, 150 and 450 MHz to 850 MHz so that more channels may be accommodated. The FCC has responded by opening a new band from 806 to 881 MHz, to be used exclusively for mobile communications. If this plan is implemented, there is going to be quite a haul of VHF surplus FM gear on the market from people evacuating to the new band. Watch this column for more info, or see March 72 *Microwaves*.

An added note: Motorola objects to the AT&T plan, and instead asked for another band at 900 MHz; no FCC action on this proposal is known of at this time.

New Microwave Products

Microwave Semiconductor Corp. (MSC) has scooped the bipolar industry again by announcing a 5 watt (output power) device at 4.0 GHz. At $400 apiece, I sincerely doubt you or I will put one on the ham bands soon, but don't forget that the 2N3866 was over $100 just ten or so years ago. Base and emitter linewidths of one micron allow minimal parasitic reactance while still providing maximum power gain at 4 GHz for the MSC 4005.

Last month's mention of arsenic transistors has led some amateurs to comment that 15 GHz is a pretty high frequency to be fooling around with transistors. While I must admit that 15 GHz is the state-of-the-art as far as bipolar transistors are concerned, I feel I must mention that there are commercially available FET's that have cutoff frequencies (F_T) of 40 GHz. Now, that's really *moving!*

Jim Weir WB6BHI
P.O. Box 23233
San Diego CA 92123

of others have WAC on SSTV also, and Bill XW8AX has left Laos and returned to the U.S. But alas . . . there are some 4X4's on SSTV hanging around 14.230. . . .

Well, summer is here, and may all your hamfests give Robot gear as prizes.

Dave Ingram K4TWJ

I insist that you print

KIND WORDS

With so much computer talk now interesting hams – and your interest in various usages of "73," have you ever noticed how evenly this comes out as a binary number: 1001001?

Alexander Stewart W1TD
Camden ME

Haven't noticed.

I have been in the ARRL for the last year but QST just doesn't cut it for me. Not enough articles that are really for a beginner like me, so I've had to go out and buy 73 off the stand. Your "General Class License Study" is a help for my next step which I'm sure is going to come out on the passing side. Keep up the good work. Guys like me need a mag like 73.

Earl Bach WNØAVU
Minneapolis MN

You keep up the good work, Earl. Ham radio needs guys like you.

Please accept my congratulations for your consistent production of a publication that contains useful, authoritative articles. These articles are written so they are easily understood without regard to the complexity of their subject matter.

F. W. Harland
Abington PA

I have enjoyed your magazine for some time now. I find it more interesting than QST. I am interested in your IC applications articles. How about a feature article on SSTV which summarizes the developments to date for someone who knows very little about SSTV.

David A. Bollmann
Bethlehem PA

Coming.

. . .AND A RASBERRY!

Cripes! Just shelled out one buck for your April issue! It's a catalogue not a magazine! You lost a long-standing reader!! WHEN you eliminated the jokes, W1YSD, and W2NSD/1 funny comments and went all FM it was Baaaaa!!! But turning 73 into a catalogue, phooey! I can get *free* catalogues and brochures.

No Block + No Manning + No interest = No ME!!!

Cal Emerson

If you want humor, read CQ. Their April Fool survey article was a laugh and a half.

EUROPEAN TOUR

"Three solid weeks with Wayne Green?" All I can say is *YUK*!!!

D. M. Casselman WAØGSY
Conway Springs KS

Three solid weeks with D. M. Casselman? Double YUK!!!

PLATE PLIGHT

There is so much to say about the April issue I'll try to keep myself down to a few choice words so as not to take too much of your time. This issue was so great that a few of us got together just to sit and praise it last evening! You really hit the top with this issue!

Watch for some fire from Nebraska in the next year or so about license plates: seems the legislature here said anyone who wanted special plates could pay a $50 fee and many people did. Then they saw amateurs with call plates and learned that the hams paid only about $2. People got mad and wrote their congressmen. Now we wait! I like Alaska's system for amateur plates if rumors are correct: $1.00 total cost if vehicle has mobile equipment regularly installed in it. This could encourage some growth in the ranks if nothing else will.

G. Wayne Heck WB9HJM/Ø –NØTUB
7401 South 33 St.
Omaha NB 68147

I want to tell you about a bum deal we are about to get from the Michigan legislature. Michigan amateurs were able to get their call letters on their auto plates for $2.00 over the regular cost of plates. This isn't anything new but what is new is that some group has pushed a bill through the Senate (March 16, 1972) boosting the fee to $25. The bill is Substitute Senate Bill 240, I believe. By chance, one ham (W8AQA Saginaw) found it out and the result is angry muttering all over Michigan. If it can happen here it can happen in other states. We know CB'ers have been stumping for their

(continued overleaf)

call letter plates for some time. This may the the state's way of shutting them up and at the same time stopping complaints of favoring certain groups, but I think it still is a bum deal.

R. Dring K8YQC
1100 E. Hill Rd.
Flint MI 48507

It seems like the license plate issue is up again in different parts of the nation. How have other groups worked to repeal this form of discrimination against hams? Please send information to either/or both of the gentlemen above and send a copy to 73.

Amateurs all over the world must have a quiet chuckle to themselves as they watch the goggle-box and anything to do with radio crops up – for the TV-men ALWAYS goof it! Here in England we get all your "Cops and Robbers" films and I was rather idly watching one recently when the strong arm of the law burst open the door of the baddies' hideout. The local police-inspector looked puzzled at what he saw inside the room, but the know-all FBI agent explained rather airly, "Aha, yes, that's a very high powered marine wireless transmitter."

No wonder the inspector looked puzzled, for the camera zoomed in on a typical Novice setup, complete with DX-40.

When will the film producers learn to consult an amateur?

Douglas Byrne G3KPO
Spalding, England

At our FM Symposium in Shrewsbury, Massachusetts, one ham walked around talking into a Minox camera with toothpick antenna.

DYCOMM DISSECTED

After seeing your "Dycomm Demand" story in the April issue,I thought I would share with you an experience I have had with the good folks at Dycomm.

December 21, 1971, I wrote Jim Penny at Dycomm and indicated our CD group was in the process of installing a repeater and I wanted information on the Dycomm repeater. We had been considering a Motorola unit. Two months passed, we had our money in our hands, but no word from Dycomm.

I called Dycomm the latter part of January, talked to the secretary who answered the phone, explained to her the situation, and she said that Penny was in a conference with everybody else and couldn't be disturbed. She acknowledged receipt of my letter and said that she would have him either call me back or get a letter out to me in the next day's mail. Two weeks later, nothing.

A friend who is the owner of a nearby repeater saw me a week later and I told him of my unsuccessful attempt to buy a repeater from Dycomm (he had ordered a Dycomm machine earlier but had not received it) and he said he would be talking to Penny in a few days and would mention my plight, which he did. He told me that Penny was sorry as hell and had misplaced my letter and would I please by so kind as to drop him another letter, which I did. I sent him a Xerox of the first letter to him with a note at the bottom telling him that I had also called him. *To this date I have not heard from Dycomm.* We have since bought a solid state GE repeater ($700).

I thought you would be interested in how one of your advertisers responds to requests for information. Also I guess you are not the only one who has trouble getting them to read their mail.

Name withheld

No further ads will be accepted from Dycomm for the Repeater Bulletin, 73 Magazine, or any other 73 publications.

ANOTHER CHANCE! OH, WOW!

You are probably wondering why I took so long to renew so I'll tell you. I was considering dropping you because I did not like your sideways format and the fine print was too much strain on my farsighted eyes, and also you did not put your yearly index in the Dec. 1971 issue. What I do like is your construction articles and also you keep me posted on what the other mags do wrong. I get them all.

Please push for more activity on 220 MHz even if it is FM repeaters so we don't lose it. I am a 2 meter AM operator and also some 6 meter SSB. I have also operated on 220 but there wasn't much activity so I shelved it temporarily. I decided to give you another chance so don't disappoint me with any more cockeyed formats.

Joe Murphy WA2FEK

CB'ER INTO HAM?

Reading your January issue, there is a letter from Ed Brooks Jr. W3GAB. Well I agree with him him 100% about the EIA proposal to allocate 146–148 MHz to CB hobby operations. Why get another mess started. If you give them another one of our bands, they may at a later date want more. As the saying goes, you give them an inch and they will take a mile. I know several CBers who are running against every regulation the FCC has put forth. I have converted a few of them to amateur radio. I showed them how easy it was to get a Novice ticket. I believe that if everyone who is a ham would get together with the CBers and show them how easy it is to become a ham operator, there wouldn't be a need for the EIA proposal at all.

William D Steen WA6HBM

This is where the local ham club plays a role in building PR. With another few hundred thousand hams our voice would be much louder.

EUROPE REVISITED

Top Tour and Swissair vacation plan as described in CQ for March may indeed appeal to some amateurs and be a good undertaking. But, one should carefully check what one is getting and total *all* the costs involved against other available plans. The Swissair ad in CQ makes reference to "1st Class Hotels." Some of those described under the plan are first class but some are definitely not. For instance, the "hotel" in Germany does not fall under any of the officially established categories of hotels of the first, second, third or fourth class. It is a so-called "Gasthaus" or inn. The hotel in Zweisimmen, Switzerland is officially listed as a hotel of the second to fourth class (depending on the room). The postal authorities in the countries mentioned who control the issuance of amateur licenses, are usually very friendly people, but the idea of obtaining your "own specialized personalized callsign," as the ad states, when native amateurs cannot generally obtain such service is stretching things. Your personalized call sign will usually be your W call followed by the normal country prefix, such as W8XXX/DL. There are other points one could mention such as: what does one see of Europe staying in insolated spots? Ever drive around in Europe during the tourist peak? Those 1–2 hour "theoretical" drives to sights of interest become 6–8 hour grinds. What is so DX'y about signing W8XXX/DL? There will be no pileups waiting to work you.

Name withheld

Visiting Europe during the summer months can be a terrible grind. My own preference is in May or in the fall – September and October, when the hotels have rooms, there are seats in the restaurants, and weather is just a bit cool, but not cold. I like the smaller hotels better than the first class Hilton type sanitized and plastic American type hotels. And who wants to sit in a hotel room watching a German-dubbed rerun of December Bride?

I'm on a 3-month business trip to Key West. Driving across country I worked into many FM repeaters and dutifully used your "FCC Official" log book that I got from the 73 booth at Las Vegas.

On the way down the Florida Keys my car with lots of antennas and the "FCC OFFICIAL" was spotted by a Citizen Bander at a service station. He passed the word down the Keys that the FCC was coming. There was a mad scramble to disconnect linears and lower antennas by the local CB'ers.

This info was passed on to me after I was here a couple of weeks.

Tom ORR W6EIF/4
Key West, Florida

These log books are available from 73 4/$1. They are designed to be used as FM mobile logs. The cover was designed to help keep fuzz off the car, the idea being to casually leave the log book on the dashboard with the "FCC OFFICIAL" facing upwards. The CB reaction is a side benefit, but one certainly worth pursuing.

CHAPIN REBUTTED

I would like to comment on your guest editorial in Jan. 72 issue of 73, which incidentally was a great way to begin the new year. An excellent edition (slim or otherwise!).

Admittedly, Mr. Chapin is well informed on the inner workings of the former IRE and AIEE, now IEEE and his arguments offer much for thought with regard to the ARRL and its obvious problems in the area of finances, membership & P.R., but to structure the ARRL in the manner he suggests is pure folly. I will agree that every organization goes through a cycle, beginning with its embryonic stage to its final plea for recognition, and ironically enough, that is where the similarity in our thin-ing also dies.

Forming a new organization by the act of merging does not guarantee continuity of the old organization, it is merely a way of saving face, in most cases, it is the final plea for recognition as mentioned earlier. Once the merger is complete the old organization is gone forever. I would like to know how Mr. Chapin is able to draw a parallel between the IRE & AIEE vs. ARRL & WHOM? *The ARRL simply has no competition.* How can you draw a parallel between the ARRL & CW & RC & TFC & Non/TFC & DX & etc.? Any rank SWL realizes that the real problem stems from the fact that *ARRL simply has no competition!* I know I repeated it, maybe by now it has sunk in somewhere between the head phones. Show me an organization or company with sole rights and distributorship of a product or service and I will show you an inferior product or service!

You know it, I know it, and Mr. Chapin knows it along with 200,000 other amateurs in the U.S. We live in a country whose economy is based and founded on competition, yet we sit on our tails for 50 years and let ourselves be led around and dictated to by an organization that claims 27% of our lot. C'mon fellows and YL's, wake up, we can do better than this!

For my part, since all the dissension began 3 years ago, and new organizations have cropped up (one of which is doing very well) and I'm proud to be a member of Nu Sigma Alpha, amateur radio has never been more exciting. Let's face it, competition is food for the soul, we all must have it, win or lose, we do the best we can for our colors. I can think of nothing more boring than to boast that I belong to the one and only major ham radio organization in the country. We've had 50 years of this drudgery, and another 5 or 10 years would parallel the Chinese water torture. So let's let ARRL continue the way they wish, let's develop one or two more organizations and with it develop some friendly competition for a change. It may uncover a few dusty old rigs, solidify the present membership of ARRL and bring back some of the competitive spirit into an area where it has been heretofore virtually non-existent.

Bob Linker WA9VIR
Chicago IL

I cannot agree with you more. It is only with competition that products improve and progress is made. Any company or organization that has a monopoly stands only to protect its monopoly and great efforts are often made to crush any smaller organization that threatens to upset the status quo. About a decade ago, a small group organized the Institute of Amateur Radio. This organization promised to make many resounding changes in our hobby; but this proved to be such an earth-shaker that the well established organization took great efforts to stop the competition.

What can be done now? Well, for a start, a new organization is needed to offer services, produce some sort of information disseminating system, and present ideas to its membership. The resultant competition need not be vicious nor cruel, but may be done with a keen eye to the other to see what is being done so that it may improve upon the latest offerings. The consumer has the ability to vote for the system he approves of most, and that vote he casts is in the form of the dollar. Obviously the organization that offers the most will win. That which offers nothing will stagnate.

The following letter was received by Peter Lovelock W6AJZ, for his role in saving two Navy aircraft from disaster.

I wish to thank you for the excellent assistance which you, as an amateur radio operator, gave the United States antarctic program on February 28, 1972. At that time two United States Navy LC-130 aircraft had been forced by headwinds to turn back on a flight from Christchurch, New Zealand, to McMurdo Station. Although the planes had been able to inform McMurdo of their change in plan, due to high latitude communication interruptions neither they nor McMurdo were able at that time to notify New Zealand or to request the needed lighting at the airports there.

By working an amateur circuit with Palmer Station you were perhaps the only person in the United States in radio communication with Antarctica at that time. By relay through Palmer, and thence through you to the Office of Polar Programs, McMurdo Station was able to report this operational emergency. We were then able to telephone New Zealand authorities to verify that the situation was known to them and that the airports were ready to receive the flights. Both planes landed safely.

Your prompt and capable assistance provided a reassuring backup communication capability for which all concerned are grateful.

Joseph O. Fletcher
Head, National Science Foundation

MARKETING MAGIC?

Reference the "thin 73" item at p.10 of the December 1971 issue. Was one of the Massachusetts bandits, by any chance, my favorite anathema, Herb Gordon of Woodchuck Hill? As your files will disclose I wrote you on Oct. 2, 1970, concerning my efforts to induce that individual to either ship merchandise ordered or refund my payment for it.

Ultimately I turned the matter over to my attorney and all normal legal steps of a preliminary nature were taken. Gordon blithely ignored all correspondence (including mine), so we decided it would be ridiculous to spend a couple of hundred dollars in court to recover $99.95, the amount of the check I had sent Gordon. I publicized his performance via a couple of OT organizations to which I belong. I wonder if he is still in business?

In any event, I'm minus the $99.95 – and the wattmeter.

Further concerning material in recent issues. You have indicated an interest in the possibility of introducing things of a new nature which might have departmental aspects. So how would you like to bankrupt the organization via a thing that might be entitled "Marketing Magic?" It would be concerned with the type of reaming I took from Gordon. It would report complaints from amateurs who, in fact or in fancy, have been victimized by suppliers. It would be based upon letters sent to 73 by victims such as W1GAA. It would contain nothing libelous, but would rather constitute a factual and objective record that would, hopefully, differentiate between the suppliers who deal above the table and those who don't.

Allowing for my undoubted bias, I think something of this nature would

LETTERS CONT.

be a real service to all hams. But of course it might take 73 out of the picture – or, like the various consumer's magazines, it might start a boom for you.

I'd be delighted to edit such a column. What do you think?

Al Smith W1GAA/K3ZMS
Temple NH

There are a few cases where a warning to the reader is in order, but a good percentage of the complaints that have been received at 73 have been exaggerated. The 73 policy has been to refuse further advertising to firms which generate legitimate complaints from customers. A good percentage of the 73 advertisers are involved with mail orders so we try to do everything we can to make sure that everything is on the up-and-up. 73 is also suing Mr. Gordon, though not with any remarkable success.

Be The First!

Are you going to let the EIA steal one of our most promising ham bands without a fight? Are you going to sit still while this piracy takes place? Or are you going to fight back? Are you going to get on 220? Are you going to help get a repeater on 220? Are you going to let the manufacturers know that they can't buy our ham band by lavishing dollars in Washington?

To help you get the spirit started with your club 73 is offering these shirts – 220 – USE IT OR LOSE IT – you may be the first in your club and make everyone eat their heart out. Wear these to hamfests and conventions – let's get the word out.

These 220 shirts are $2.50 each postpaid – state size desired – small, medium or large – state color desired as long as it is blue. USA only.

SIX ELEMENTS ON TWENTY METERS

Literally hundreds of articles have been written over the past few years describing antenna arrays ranging from dipole simplicity to full-size 40m quads. Still, it seems that most hams do not have as good an antenna system as they would like to have. There are two major reasons for this: They don't have the room or they don't have the money. Well, here is a high-gain antenna which was built in a 55 x 35 ft back yard at a total expense of about $5 for antenna wire plus some leftover hardware from a 75m dipole.

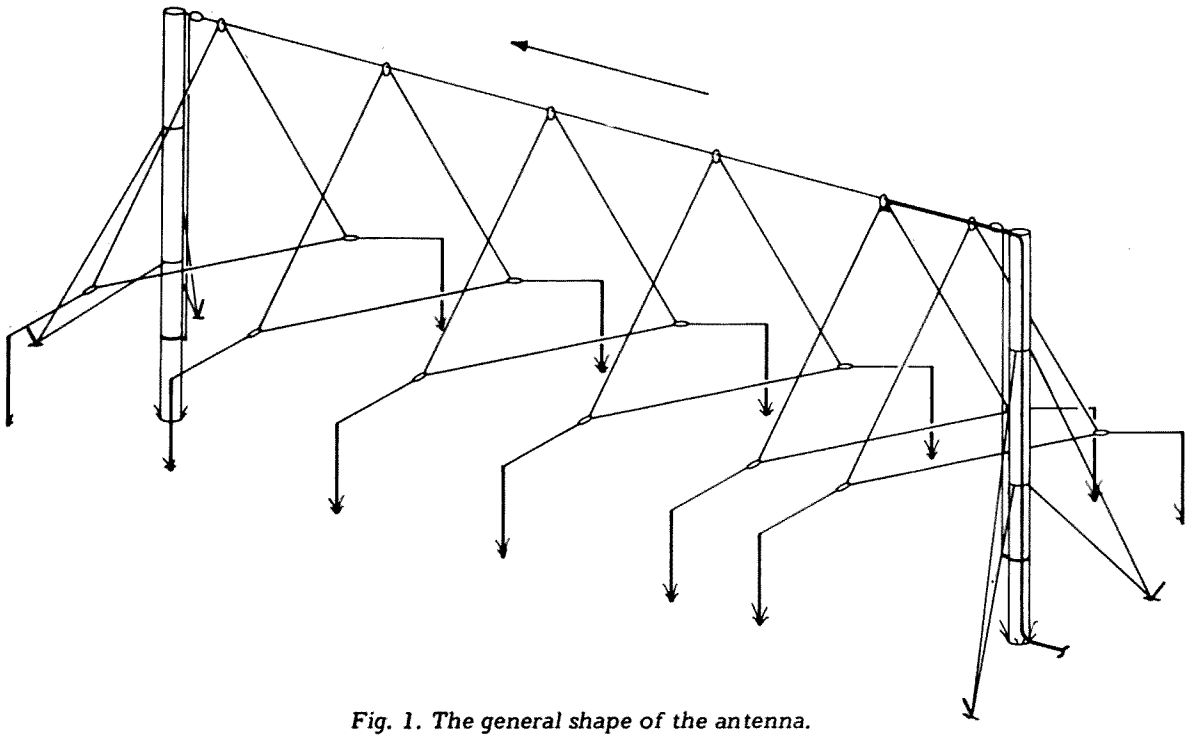

Fig. 1. The general shape of the antenna.

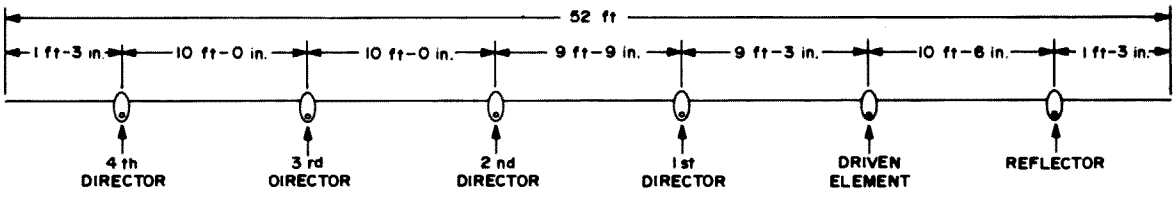

Fig. 2. Spacing of the elements on the support wire.

Checking back over the past two years of 20m operation I discovered that 62% of all contacts were with stations in Europe. The remainder were mostly contacts in Canada, South America, and a small country to the south known as the U.S. Although I was working a fair number of stations, the reports were usually, "You have a good signal here, but there is plenty of QRM on the frequency, 73 and hope to see you when the band is quieter." Of course, the band has not yet quietened down. Since I enjoy ragchewing much more than the quick "report exchange" contact, I decided to take stock of what I had in my junkbox and build the best unidirectional antenna I could devise in the space available.

My search complete, I came up with two 33 ft TV masts, a few hundred feet of guy wire, and a box of egg type strain insulators. After purchasing 450 ft of antenna wire, a roll of nylon clothesline, and two small pulleys, I had all the parts for my superbeam. Several months ago I had the idea of suspending a quad from a wire boom. Closer examination of this idea showed that if the square element configuration was to be used, two booms would be required, if the diamond configuration were to be used it would be difficult to form the square shape necessary and the elements themselves would almost touch the ground.

Suddenly while playing about with different element configurations, I realized that the most compact shape with a 1λ perimeter would be a triangle. So I came up with the antenna shown in Fig. 1. This requires only one supporting wire, and the element shape can be adjusted so that the height above ground is about 7 ft. Although this sounds low, it turns out to be just high enough to mow the lawn, yet low enough to reach easily for pruning. With the guys which hold the elements in shape attached to a fence at the edge of the yard, the forces are directed to the side instead of downwards, thus putting less stress on the supporting wire.

Although I will explain the method of construction in considerable detail here, the mechanical structure is not very critical and is only presented for the use of those who wish to duplicate my antenna exactly.

First, measure off a 52 ft length of guy wire, which will be the supporting cable. Slide six of the strain insulators onto the wire and space them according to the

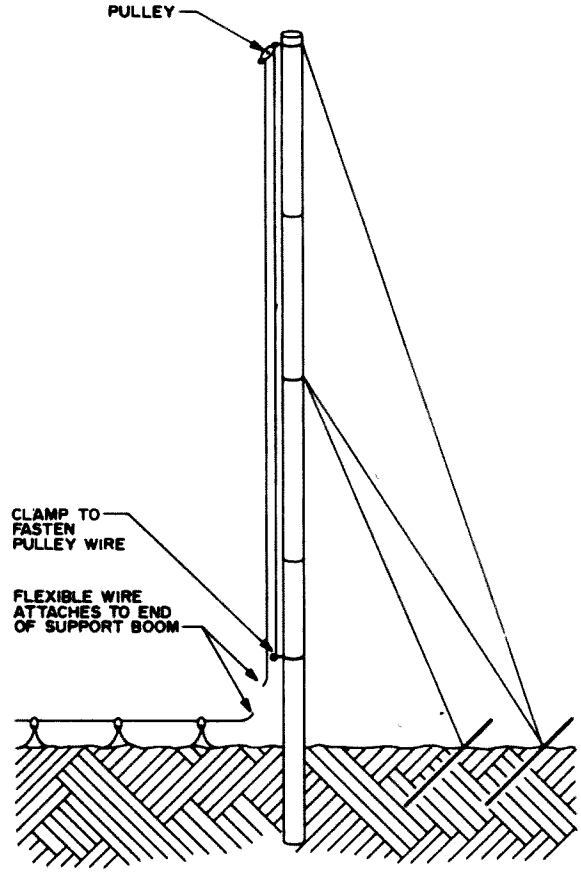

Fig. 3. Details of masts. Do not anchor guys to ground until the mast is vertical. Then tighten guys as tension on the antenna is increased.

spacing shown in Fig. 2. The insulators I used have the two holes drilled perpendicular to each other, which makes them excellent for supporting the elements of this antenna. Electrical tape was used to hold them in position.

Second, set up the masts according to the details of Fig. 3. The poles I used are TV masts made to a length of about 33 ft each by adding three 10 ft sections with swaged ends and a 4 ft scrap of tubing to be buried in the ground. A pulley is attached to the top of the mast and 50 ft of flexible guy wire is pulled through it. This will be used to lift the antenna into position after the masts have been erected and lower it for changes or servicing. Two guys attached adjacent to the pulley are used to balance the tension on the supporting wire. In addition, two more guys are attached halfway up the masts to hold them straight. The entire assembly is light enough to be walked up into the vertical position and dropped into a 3–5 ft hole. The earth can then be filled in around the mast and the guys temporarily anchored.

Next, measure the wire for the elements according to the table in Fig. 4 and insert the wire in the insulators as shown in Fig. 5. Make sure you do not mix up the elements at this point. Add two more insulators to each element and spread the wire out on each side of the boom so that it will not tangle when the antenna is being lifted into place. The feedline should be attached to the driven element and taped along the support wire to the end nearest the shack. Any 50Ω coax will work well (depending on the power you are running). Incidentally, the loss in RG-8 is 0.7 dB/100 ft. The loss in RG-58 is 1.7 dB/100 ft. In watts that means that 100W output from the transmitter at the end of 100 ft of RG-58 is only 68W at the antenna. But with RG-8, 100W at the transmitter means 83W at the antenna.

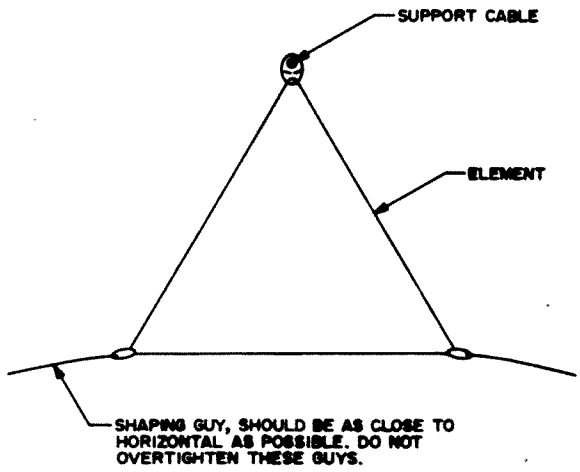

Fig. 5. Details of the element mounting.

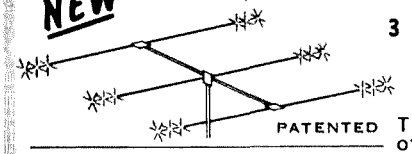
Next, attach the support wire ends to the wire on pulleys of the masts and hoist the antenna into the air. Attach nylon clothesline or heavy string to the insulators and pull the elements into a triangular shape. These guys should be attached as far from the antenna as possible or even better as high from the ground as possible. This is to prevent the strain of the guys from pulling the support wire out of shape.

Now you are ready to prune the elements. This can be done by setting a field strength meter in front of the antenna and trimming the elements for a maximum reading. If this is not possible, a reasonably good approximation can be made by resonating the elements to the frequencies shown in Fig. 4 with a grid dip meter. To be sure that the calibration of the grid



Element	Length of Wire Needed	Resonant Frequency
Reflector	71'9"	13.8 MHz
Driven Element	70'0"	14.17 MHz
First Director	68'3"	14.60 MHz
Second Director	66'6"	14.90 MHz
Third Director	64'9"	15.40 MHz
Fourth Director	63'0"	15.90 MHz

Lengths are given for a resonant frequency of 14.170 MHz. If the frequency is higher, they should be shortened accordingly. IMPORTANT: These lengths are rough estimates and should not be used without pruning with the antenna in the air.

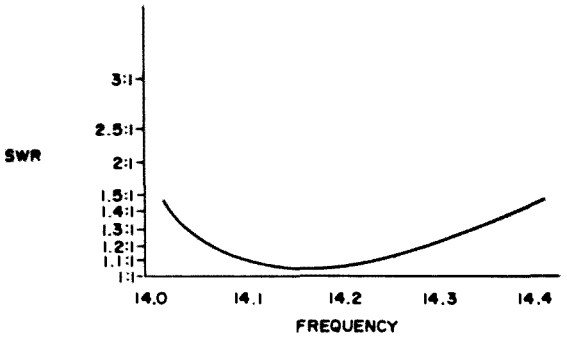

Fig. 6. A plot of swr vs frequency shows that the antenna is quite flat across the entire band. In fact the swr does not exceed 1.5:1 on any frequency.

dipper is not being pulled by the antenna element, a communications receiver can be connected to the antenna which will pick up the signal and assure accurate calibration. Last, trim the driven element for a minimum swr.

The first time I plugged the antenna into the transmitter I thought something had gone wrong with my swr meter. No matter how far I advanced the sensitivity I could not get a reading in the reflected position. The swr was a flat 1:1. The final resonance swr is shown in the graph of Fig. 6.

The first station I worked was OZ7KB, who reported my signals to be S9, and one of the few VEs coming through at that time. Receiving, his signals were also S9. A few more contacts with more S9 reports using 150W PEP confirmed that the antenna was working well.

Comparison reports with a vertical show a consistent 10 to 15 dB gain on both receive and transmit. The antenna has the added bonus of cutting out the QRM I used to get from the South American kilowatts.

Since I am no antenna engineer, I cannot give any rigid theories as to how or why this antenna works. I do not even know what the polarization is. All I can say with certainty is that it works for me and I am quite pleased with its performance. Incidentally, I do not see why the antenna can't be extended to more elements if the room is available. Like, how about a cheap 12-element 20m beam?

SLOW-SCAN TELEVISION

"Slow Scan? What is that, OM?"

Yes, believe it or not, that is the question I am asked time and time again when I have transmitted amateur television Slow Scan pictures on 14230 kHz and announced the fact on SSB, only to find some DL, OK, SM, and even W/K station responding as if I had only transmitted a phone CW call. When I reply that I am ready for Slow Scan transmissions and ask, "Have you that facility?", they appear puzzled:

G5ZT at his station.

"Slow Scan? What is that, OM" When I explain that I have been sending Slow Scan amateur television pictures, they invariably say something like this: "Sorry, OM, I did not know that sound was Slow Scan. I have often heard it but thought it was some commercial RTTY or high speed Morse – I deliberately used the frequency for testing and tuning-up purposes. Television on these DX bands would be most interesting . . . please explain all about it and tell me how I can get equipment going and where I can get the equipment or circuits."

Hence this article to explain in simple terms what SSTV means and what equipment is required. Much has been written about this subject but it seems to me that it has been too technical for many amatuers. They have just given the article a cursory glance and then forgotten all about it.

SSTV is a means whereby amateurs can transmit and receive television pictures world-wide using the normal narrow band wavelengths in the amateur bands of 80, 40, 20, 15 and 10 meters.

All amateurs will understand the principles of commercial broadcast television.

DRAKE TR-22

Versatility plus!...in a 2 Meter FM Transceiver

Over-the-shoulder, mobile, or at home

Completely transistorized, compact, portable. Capacity for 6 channels. Built-in telescoping antenna, and connector for external antenna. Use barefoot or with accessory amplifier. External 12 VDC or internal ni-cad batteries, built-in 120 VAC battery charger.

Complete with: Dynamic Mike, O-T-S Carrying Case, 120 VAC and 12 VDC Cords, Speaker/Headphone Plug and 10 Ni-Cad Batteries.

$199.95 Amateur Net

AA-22 Amplifier $149.95

SSTV DX! Transmitted by W4LAS, the picture is of his niece.

This must be transmitted and received on VHF or UHF because of the wide bandwith – anything from 2 MHz to 6 MHz depending on the country. To use a minimum of 2 MHz bandwidth for amateur televison means that hams have to use the 432 MHz or even higher frequency bands, which they do, but activity is comparatively low and communication is normally only a few miles, seldom out of the amateur's own country.

By using SSTV, television pictures can be transmitted using a bandwidth of no more than 2.5 kHz so that transmission is perfectly possible in the 80 to 10 meter bands where world-wide communication is quite normal. Not only is this possible, but, because of the narrow bandwidth used, it easily complies with international regulations, covering no wider a channel than SSB does and even less than that of AM or FM.

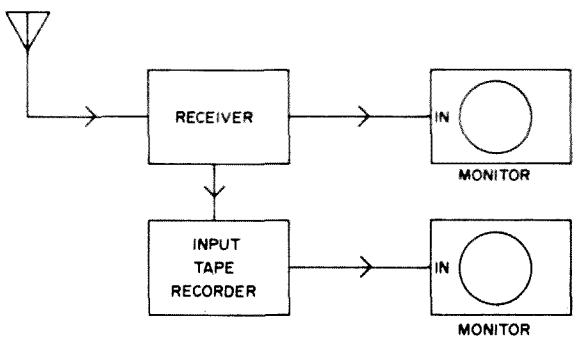

Fig. 1. Block diagram of interconnections for the short-wave viewer and transmitter for television reception.

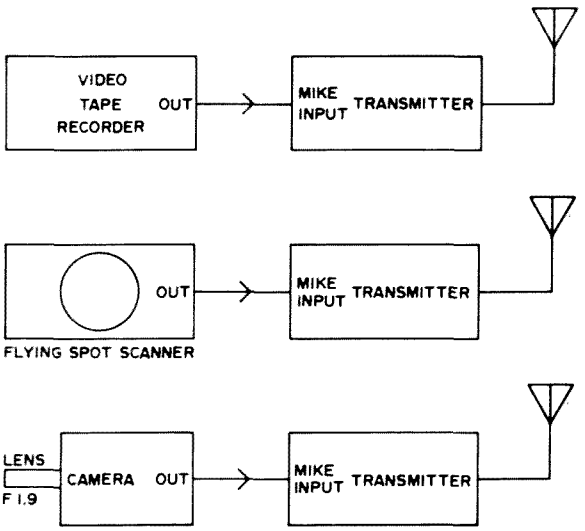

Fig. 2. Block diagram of interconnections for the transmission of pictures.

The difference between amateur television on 432 MHz, where objects can be seen moving, and SSTV, is that the picture must be static. Call signs, photographs of self, yl, xyl, family, shack, cartoons and written messages can be easily transmitted anywhere in the world with surprisingly good definition. But it is fascinating to contact a station 10,000 miles (or even 50 miles) away and exchange a series of pictures.

To make this technically feasible on a world-wide basis, a standard has been reached which all SSTV amateurs use, as follows:

Number of lines	120
Time per frame	8 seconds
Modulation (white)	2300 Hz Modulation FM
Modulation (black)	1500 Hz
Sync.	1200 Hz
Sync duration	
Horizontal	5 milliseconds
Vertical	30 milliseconds

Normally after transmitting video signals, the same frequency is used for sound to announce the fact that you are looking for slow scan contacts. Although technically it is possible to use vision and sound simultaneously on either sideband, I have not heard of this method in use yet. For reception of the pictures, all that is necessary is for the output from your communication receiver speaker terminals to be fed into a cathode ray assembly called the monitor.

The cathode ray tube is the special long-persistence type, usually P-7 phosphor. The incoming signal is truly slow scan and, unlike commercial television which appears to be instantaneous due to the high line and frame rate, appears to *paint* the picture from the top left to the bottom right of the cathode ray tube, taking a total of eight seconds to complete the picture on the tube. That is why you have to use a P-7 phosphor. When this eight second period reaches the bottom of the tube, the sync signal starts the process over again. The normal practice is to transmit each picture for three or more frames, enabling the receiving amateur to get a full picture and tape record. Intensity of the picture is frequency – modulated according to the standards already listed, i.e. for highest brightness, 2300 Hz, for black, 1500 Hz, and for line and frame synchronization by 1200 Hz blacker than black pulses at the line and frame rates. The bandwidth is thus limited to the normal voice grade communication frequencies into the transmitter microphone socket for transmitting and into the receiver circuits for reception.

Now don't think that this is too complex for you. I only commenced operating in this mode on April 22, 1971, and have already had over 80 two-way television contacts with Greece, Sweden, Italy, Alaska, U.S.A., Puerto Rico and Guadeloupe Island. I have received short-wave viewers' reports from Norway, Russia, Czechoslovakia, Singapore, Austria and Australia. This should prove to the doubters what a great deal of activity

Typical logo used by SSTV hams.

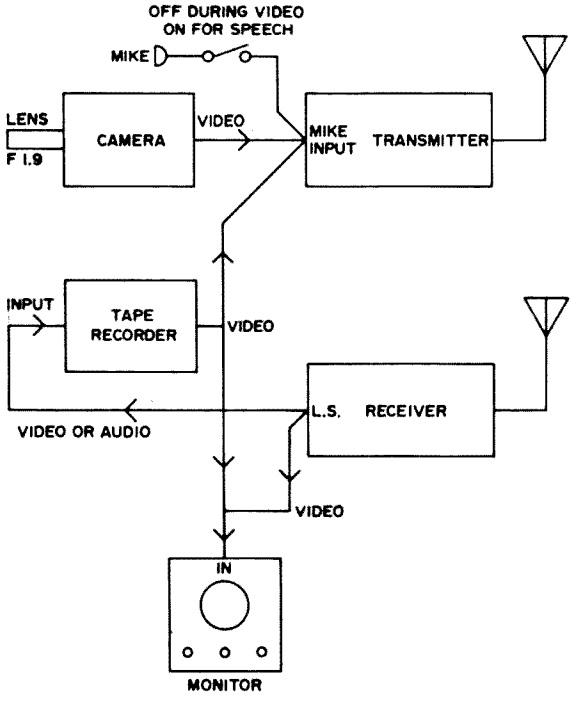

Fig. 3. SSTV interconnections at G5ZT.

there is; it is increasing daily. I understand that there are over 30 countries using SSTV and that some amateurs already have over 20 C. to their credit. I predict that by 1975 the first DX/CC/SSTV certificate will have been issued.

It is a pleasure to find the slow scan amateurs such a friendly bunch, with no rush to get rid of you for the next QSO. Contact for an hour or more is quite normal and the experts are always willing to give you every assistance and advice. The most popular frequencies in use are 3845, 3740, 7050, 14230, 21100, 21430, 28100 and 28600 kHz, the two main long distance frequencies being 14230 and 21430 kHz.

All you have to do is to tune your receiver to the signal which sounds similar to RTTY or high speed Morse with a noticeable "pip" every eight seconds. If you hear the station on sound then that is the correct tuning position to receive the picture.

A tape recorder is almost a "must," since you should tape all signals. Then you can play them back at leisure for checking purposes, proving reception to your friends or taking photographs of the pictures.

For transmitting you can use any of the following methods to feed the picture into your transmitter microphone socket:

1. Use a video tape recorder. Get an SSTV amateur to make a video tape of your call sign, photographs, etc. All you do is feed recorder output into your transmitter microphone socket.
2. Use a Flying Spot Scanner. With this, you can make up your own version of your call sign to feed into the transmitter.
3. Use a video camera. This is the ultimate for SSTV. You can have a target stand in front of the camera on which to place any writing or photographs or you can turn the camera on yourself, your shack, etc. Camera output again is fed into the transmitter as in the other methods.

The video signal is adjusted to give the same transmitter rf output level as your voice peaks, or just slightly lower, being careful on SSB not to go beyond the specified carrier insertion levels or, if using an AM or FM transmitter, the same levels. If, for example, your SSB transmitter instructions say speech peaks of 150 mA, then I would adjust the video level to around 100 mA.

If you build your own equipment, see the appendix for numerous articles on equipment. If you want to get on the air quickly by purchasing commercial equipment, there are three firms that I know of producing equipment:

Robot Research Inc., 7591 Convoy Court, San Diego CA 92111. Camera and monitor.

The ID picture of FG7XT, as received in England by G5ZT.

This is how SM4AMM must look after receiving TVI complaints.

L.E. Babcock & Company, Inc., P.O. Box 281, Acton MA. SSB transceiver with SSTV add-on units. See 73 magazine May 71.

E.K.Y. Video Vision Co., Box 15, Stockholm NJ. Monitors, monitor kit sets. See 73 magazine April 71.

It will take you no more than one hour after receiving the ready-made equipment to be on the air . . . as simple as that! Reception is remarkably good since even signals as low as S3 will provide a picture and S7 signals will take a lot of QRM punishment. Various simple cabling connections for the viewer and transmitting amateur are shown in Figs. 1 and 2.

The big advantage of taping all contacts is that you can edit the tape, keeping the best pictures and sound reception as a permanent record to photograph at your leisure. I used a standard Philips tape recorder which cost me $10 secondhand, and I bought an ordinary camera for $20. Having set up the camera for correct aperture and focal length, give the film an eight second time exposure when the picture on the monitor starts at the top. It will take eight seconds to reach the bottom. The photographs in this article were taken by this method. Times for long distance communication will be the same as for phone contacts mainly operating on 14230 kHz or 21430 kHz. It is just a question of being on the air at the right time to catch the DX – often 0300 GMT for me!

BEAMING the VERTICAL ANTENNA

The user of a groundplane or trap-vertical type antenna experiences the limitations of its omnidirectional characteristics. Heavier QRM during reception and reduced radiation in a desired direction are inherent to this type of antenna, despite the low vertical angle of propagation which is favorable for DX work.

One classic solution is to utilize two identical verticals, spaced ¼-wavelength apart, and phase driven with an appropriate length of interconnecting feedline. Such arrays will exhibit a cardioid or "figure-8" horizontal pattern, dependent upon the phasing-line length and feedpoint. This arrangement is suitable only for single band operation due to the phasing requirements, and in the case of trap verticals may involve the significant expense of the duplicate antenna. The directional pattern is broad, fixed to the plane of the twin antennas, and can only be reversed by somewhat complex coaxial switching of the phasing line.

The fact that verticals lend themselves to the application of parasitic elements in Yagi-type configurations, seems to have been somewhat neglected. The purpose here is not to give detailed construction of such an array, but rather to present some ideas which I have found to accomplish effective directional characteristics for my commercial trap vertical. These are equally applicable to any ¼-wave vertical, and may be adapted to the needs and space availability of the individual. The final section describes how such parasitic elements may be fabricated from readily available materials at very modest cost.

Vertical Reflector

The simplest application of a parasitic element is a vertical reflector spaced 0.25 wavelengths from the groundplane driven element. The photograph shows a 21 MHz reflector used in conjunction with a popular trap vertical. Figure 1 illustrates the arrangement of the reflector with a single band groundplane antenna.

0.25 wavelength spacing between elements is suggested for several reasons: (a) It affords the optimum gain for a single parasitic element. (b) The reflector length is an electrical ¼-wave at this spacing to achieve correct phase relationship. (c) The base of the reflector should be connected to the same electrical ground as the antenna. This may be achieved by

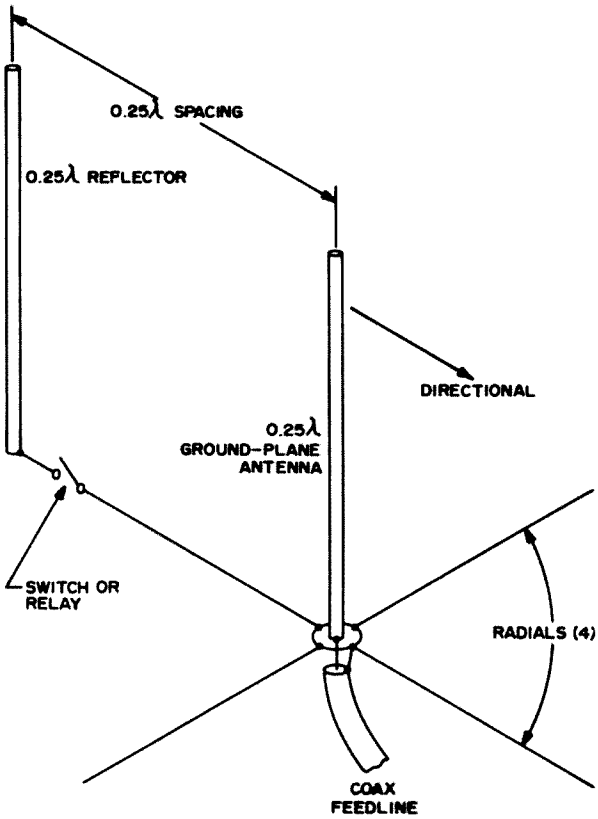

Fig. 1. Simple reflector for ground plane antenna.

connecting it directly to the end of one radial used with a groundplane. (If the vertical antenna is ground mounted without radials, a ¼-wave wire should be run from the base of the reflector to the antenna feedpoint ground.) (d) 0.25 wave spacing has the minimum effect on the antenna's radiation resistance, and thus minimum change to feedline matching and SWR.

If the base of the reflector is otherwise insulated, the element may be made non-functional by breaking the connection to the radial wire. This can be done by inserting a switch, or remote operated relay, close to the reflector base. Directional or omnidirectional operation may then be selected at will.

True, the single, fixed position vertical reflector is constrained to "beaming" in one direction. But when some added punch to a particular part of the world is desired, the 5 dB gain from this simple expedient is well worth a few dollars for the aluminum tubing used. The equivalent increase of x4 power would cost up to one hundred times as much.

Director elements may be added in-line for improved gain and front-to-back ratio. However, to achieve worthwhile results directors must be spaced 0.1 to 0.15 wavelengths from the antenna (and each other). This requires that they be adjusted to an electrical length shorter than 0.25 (dependent on actual spacing) for correct phasing. The additional elements and close spacing will significantly reduce the antenna feedpoint impedance, requiring special matching arrangements if SWR is to be kept low on the feedline. This is not conducive to switching out the parasitic elements for omnidirectional operation, unless a complex relay system is acceptable. For the 2–3 dB extra gain, the cost and effort increases out of proportion, and the single reflector offers the most for the least.

For those who desire it, formulas for deriving the proper length to spacing of directors are the same as those used for horizontal Yagi-beams, divided by 2.

Variable Directivity

While the single fixed reflector provides an easy method of fixed direction beaming, the ability to vary directivity may be ultimately desirable. Figure 2 depicts an array utilizing four fixed directors arranged around the vertical antenna at 90° intervals. The eight-position switching system shown operates relays at the base of each reflector, so that one or two reflectors are activated for a given switch position. This effectively allows 360° rotation in 45° steps. Since the beam width with a single reflector, at ½ power points, is approximately 60°, the rotational capability is pretty adequate.

A simpler version can be made using a four position switch, and accomplishing electrical "rotation" in 90° steps. However the difference in cost is just that of the switch.Another method of beam rotation, applicable to the 28 and 21 MHz bands, is shown in Fig. 3. Here the reflector (and if desired, director) are mounted on a rotatable boom. The boom is attached to a bearing and bracket assembly, clamped to the mast which supports the vertical antenna, and is at "ground" potential. The boom can be rotated by the "armstrong" method, and incorporate a means of locking in a

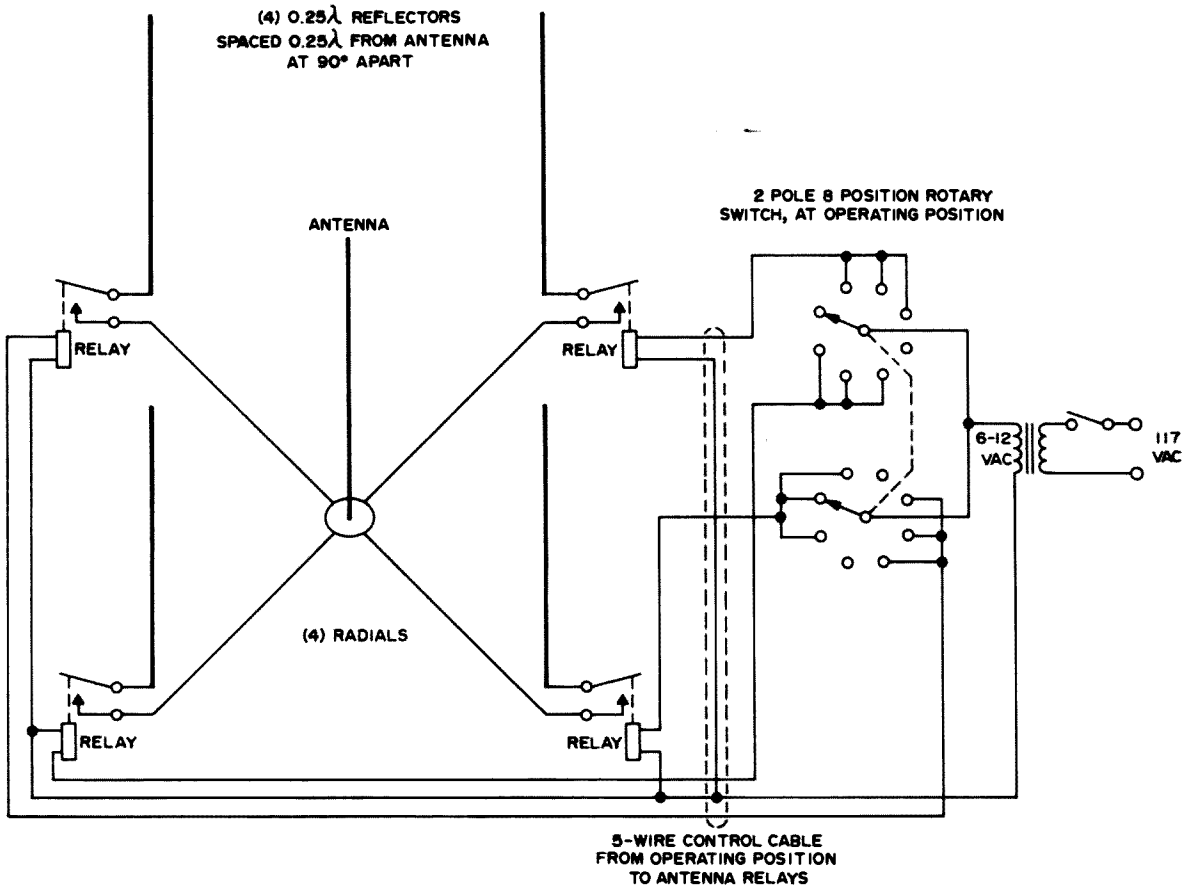

Fig. 2. Four reflector array for variable directivity.

prescribed direction. Or a suitable motor drive will permit remote operation from the shack.

The parasitic elements may be clamped directly to the boom, in which case the permanent electrical connection will not allow for omnidirectional use of the antenna. If the latter is desired, the parasitic elements must be insulated from the boom and connected by relay switching for beam application. Detailed methods appear under the constructional section below.

A single boom may incorporate parasitic elements for both 28 and 21 MHz, either by using separate elements of the right length and spacing or, alternatively by using a method described under the "Multi-Band" section that follows. In the latter case a compromise in spacing will be necessary.

Multi-Band Applications

So far we have considered using parasitic elements basically for a single band. For those who have a favorite DX band, this may prove adequate. But for the man who has a five band trap vertical, and wants to benefit from DX on more than one band, the problems multiply.

If you have a lot of real estate, or a very large flat roof and complacent neighbors, you can extend on the method of Fig. 2. All it takes is four more reflectors and relays for each band, suitably spaced from the trap vertical. This is possible for 28 through 14 MHz. For lower frequencies, full length ¼-wave reflectors get to be big and cumbersome, and a full 5-band array with 20 assorted elements is an unlikely prospect for the majority.

The situation can be compacted by using a 3/8-wave reflector on the upper of two bands; say 14 and 7 MHz. The reflector will be long on the higher frequency band and display inductive reactance. This may be adjusted by incorporating the correct value of capacitve reactance between the base of the reflector and the groundplane (radial wire). Similarly, the reflector will be short for the

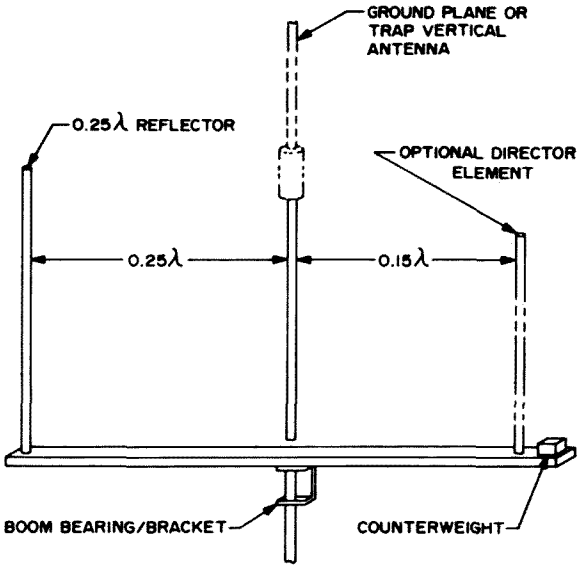

Fig. 3. Rotatable reflector for vertical antenna.

lower frequency band, with capacitive reactance which can be tuned with a series inductance.

The 3/8th wave reflector for 14/7 MHz will be approximately 24 feet high; probably the practical maximum for most installations. However the principle can be applied for 7 and 3.5 MHz where space permits, and strong enough material is used for the 50 foot height.

A 3/8th wave reflector for 28 MHz can be resonated with a series inductance on 14 MHz. Since the reflector length is about 12 ft, it can be resonated both on 21 and 28 MHz with different values of series capacitance, permitting triband operation with a single parasitic element. Figure 4 illustrates the triband reflector, using two relays to insert the appropriate values of capacitance or inductance. Omnidirection is obtained by switching to one of the bands not being used.

In all cases the 3/8th wavelength reflector will require a compromise in spacing from the antenna. 0.25 wavelength at the highest frequency is recommended. This will result in 0.125 spacing at half frequency with inductive loading, and less than optimum gain. About 3 to 4 dB gain should be attainable with careful adjustment. In the case of the triband version, spacing at 21 MHz will be about 0.18 wavelength when the reflector is spaced 8 feet from the antenna for 0.25 wave spacing at 28 MHz. A gain of 5 dB can be achieved on both 28 and 21 MHz.

It should be noted, however, that the closer spacing on the lower bands will have more effect on the antenna impedance, matching, and transmission line SWR.

For the lower frequency bands of 7 and 3.5 MHz, a more compact single reflector may be constructed utilizing the same trap principle applied to multi-band vertical antennas. The reflector is split into two sections, insulated from each other. The lower section is made a resonant length for the higher frequency band (7 MHz). A parallel tuned circuit is connected between the two sections, and resonated to the higher frequency band to function as a high impedance at this frequency. The upper section is adjusted to a length that, in conjunction with the lower section and inductance of the tuned circuit, will function as a tuned reflector at the lower frequency (3.5 MHz).

Figure 5 shows a typical trap assembly which may be made from 2½ in. diameter standard coil stock. The parallel capacitor is a mica type, rated at 2,500V. Resonance is accomplished by removing coil turns while checking with a grid-dip meter, until the tuned circuit is adjusted to the middle of the 7 MHz band.

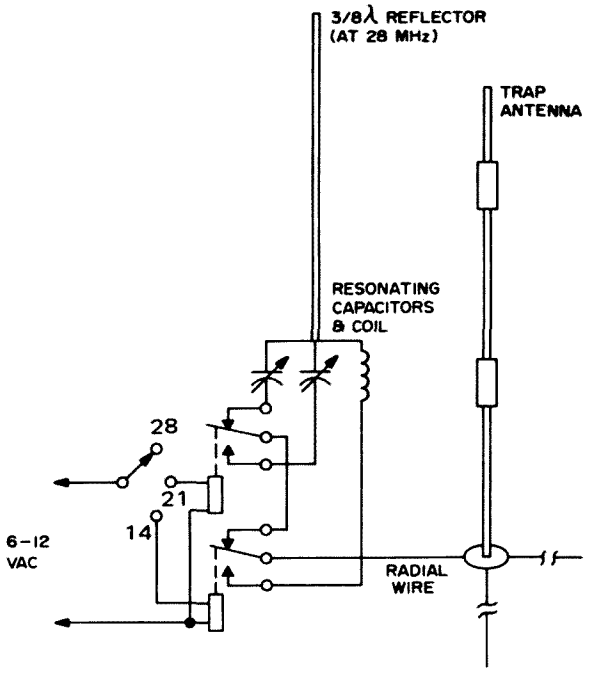

Fig. 4. 3/8th wave reflector for tri-band operation.

Appropriate values for a 7 MHz trap are: Capacitor – 50 pF. Inductance – 9 microhenrys.

Using Barker and Williamson type 3905-1 coil stock, approximately 18 turns will be required.

The trap-type reflector should also be spaced 0.25 wavelength at the higher frequency (7 MHz), from the antenna.

Construction

Previously I mentioned that parasitic elements could be inexpensively fabricated from readily available material. My source of such material is the "do-it-yourself" aluminum rack of the better hardware stores. Practically all such stores carry a supply of aluminum tubing of various diameters and lengths; the larger the store, the better the variety.

For handy reference the following table lists the standard sizes of aluminum stock which are distributed for consumer use, and are suitable for construction of parasitic elements.

Type	Outer Diameter	Wall Thickness	Length
Solid rod	3/8 in.		72 and 96 in.
Round tube	5/8 in.	0.093 in.	72 and 96 in.
Round tube	3/4 in.	0.055 in.	72 and 96 in.
Round tube	7/8 in.	0.055 in.	72 and 96 in.
Round tube	1.0 in.	0.055 in.	72 and 96 in.
Round tube	1 1/4 in.	0.055 in.	72 and 96 in.
Square stock	1 x 1 in.	0.062 in.	72 and 96 in.

The 96 in. lengths are convenient for 28 MHz use. For other bands it will be necessary to assemble elements from two or more telescoping sections. Diameters listed above that provide snug telesocping fits are as follows:

3/8 in. OD rod into 5/8 in. OD tube
5/8 in. OD tube into 3/4 in. OD tube
3/4 in. OD tube into 7/8 in. OD tube
7/8 in. OD tube into 1 in. OD tube

I assemble two telescoping sections by cutting a 1½ in. long, lengthwise slit in both walls of the larger diameter of the mating tubing. A stainless steel hose clamp around the slitted end will securely clamp the inner section after adjusting to the total required length.

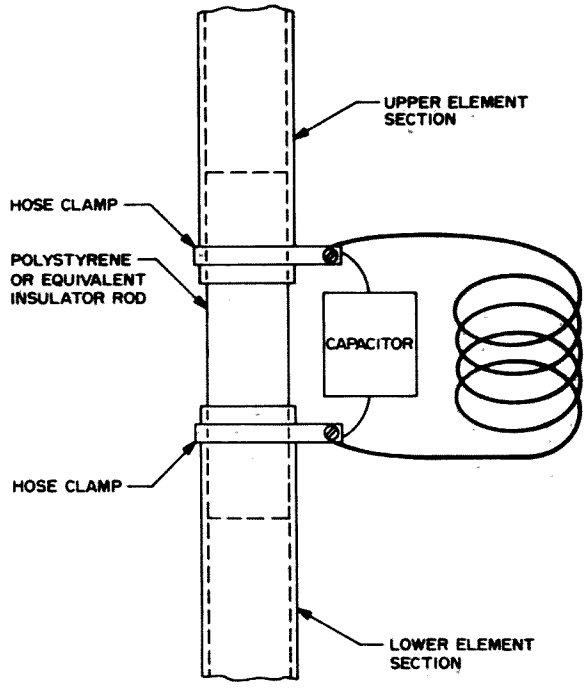

Fig. 5. Trap assembly.

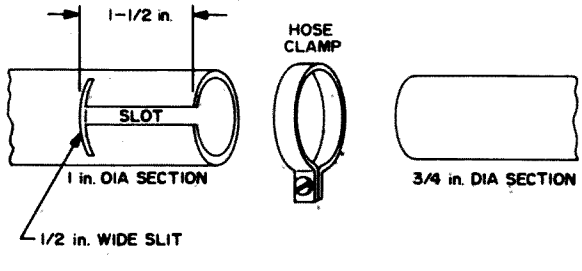
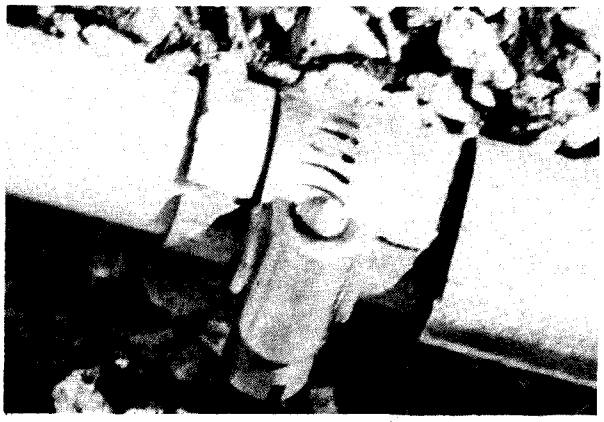
Unfortunately the 1 and 1¼ in. tubing do not fit snugly. Also you may not be lucky in finding all the mating sizes at your local hardware store. In such cases undersized inner sections may be clamped to outer sections using the trick shown in Fig. 6. I cut a 1½ in. lengthwise slot in one side of the outer tubing. At the termination of the slot the tubing is cut crosswise for half of its diameter. The slot must be wide enough that the resulting two ears can be compressed with a suitable size hose clamp to securely grip the inner section. The photograph shows such an assembly for a 15m reflector, using 1 in. and ¾ in. OD tubing.

The consumer-available hardware store tubing is made of a relatively soft alloy.





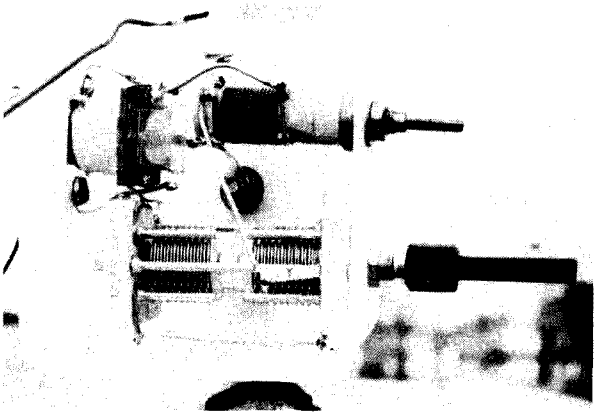


Fig. 6. Method for joining unmatched sections.

Typical joint of unmatched sections of tubing.

Weatherproof tuning box assembly.

While convenient for elements up to 20 ft in height, longer lengths are not recommended without guying. Three telescoping sections of 72 in. lengths is preferable to two of 96 in. Telescoping reinforces and reduces top weight.

Referencing Fig. 3; the rotatable boom can be constructed from a 96 in. length of 1 x 1 in. square stock, joined to a 72 in. length of the same stock with two short sections of 1 in. angle stock, bolted to the square stock to make a reinforced joint. Parasitic elements are made from 5/8 in. lower and 3/8 in. upper sections. The elements may be attached to the boom by drilling a snug fitting hole through both sides of the square stock. The element is inserted through both holes and secured on each side with a small diameter clamp. If the element is to be insulated from the boom for switching purposes, a 2 in. length of 3/8 in *ID* plastic hose or tubing should be slipped over the lower end of the element. The holes in the boom will have to be increased to accept the larger diameter of the insulating sleeve.

Weatherproof housings for accommodating relays, coils and capacitors are also available from your neighborhood hardware store. These are better known as "freezer boxes," and are made from soft polyethelyne material. The square ½ and 1 pint sizes are most suitable for protecting antenna components. The soft material compresses under hardware, forming a natural moisture-tight gasket for mounting and terminal screws.

Figure 7 illustrates a typical installation, with a DPDT relay switching a reflector tuning inductance or capacitor. The mast mounting clamp shown also serves as the electrical connection to the reflector element. The lid of the box is attached after assembly and the joint sealed with polystyrene cement. Alternatively the joint may be covered with a couple of layers of plastic insulating tape.

Conclusions

I said at the beginning that this was an idea-provoking article. Obviously it requires complementary imagination for the individual to suit his own requirements. The fellow with a vertical mounted on a roof peak will be hard put to install multiple reflectors. But a short boom (even of wood) will enable him to install a 28 or 21 MHz reflector.

Some of the techniques suggested may be combined. For example, the 3/8th wave

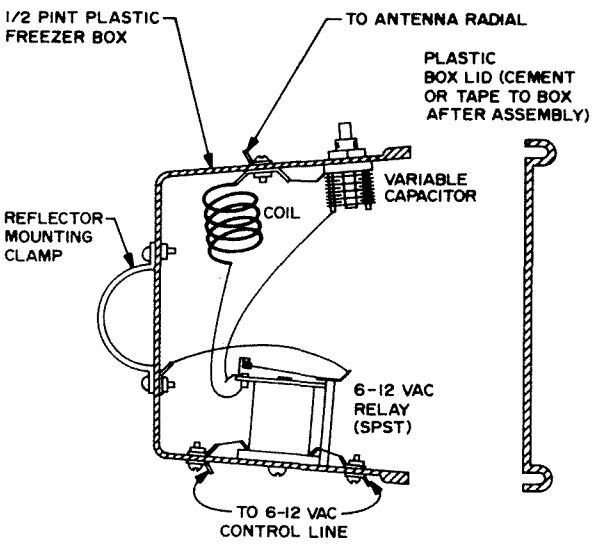

Fig. 7. Typical weatherproof box assembly for reflector tuning components.

reflector shown in Fig. 4 can be used with the rotatable boom in Fig. 3.

No formulas for element lengths on various bands have been included, as these are well covered in the regular amateur radio handbooks which should be in every shack . . . for convenience a reference guide is included.

While the hardware store aluminum stock is suggested for most applications, it must be emphasized that for heights exceeding 20 ft, or where severe wind or icing conditions prevail, precautionary measures must be taken to avoid collapse of the rather soft alloy. If in doubt, structural tubing of the 61ST variety, available from large metal supply houses, is the best bet.

ACTIVE FILTER DESIGN AND USE PART 1

If you have ever tried to "homebrew" an i-f bandpass filter, or incorporate a variable notch filter or Q-multiplier in your receiver's existing circuitry, you have an idea of many of the problems associated with passive RLC filters. Imagine being able to build a filter not only lossless, but with gain; one capable of matching different input/output impedances, without bulky and inaccurate coils, and all in less space and with better performance than the old iron core, resistance-coupled black box. Active filters, constructed both from transistors and integrated circuits, offer all of the above advantages in addition to ease of altering performance without rewinding coils or utilizing taps.

Figures 1 through 4 show simple filters with specific functions. Digging back into filter design theory for a short while will help us to see how the component values and their placement in the filter is determined. Every filter may be primarily identified by the number of branches containing L or C components. Thus, Figs. 1 through 3 all show two-pole filters of the second order; Fig. 4 a six-pole design. Resistance normally shown in RLC filters as input/output impedance is not considered part of the passive network, although other values of resistance such as that found in the coils and the value of conductance in capacitors, together known as dissipation, cause insertion loss and a degraded response shape at the band edges. Naturally, the tighter the specifications for a filter, the more complex the design must be, five- and six-pole types being common.

The design of passive filters is mostly accomplished with the help of tables containing constant values for the desired components necessary for a particular shape factor. These constant figures are then scaled to real component values. Designing RLC filters "from scratch" is a

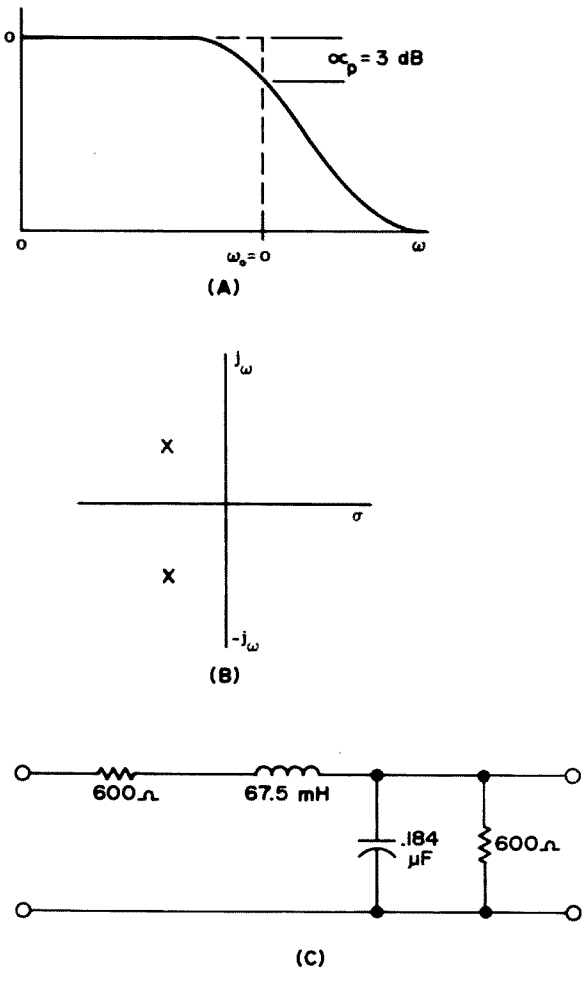

Fig. 1. Low-pass Butterworth (ideal response).

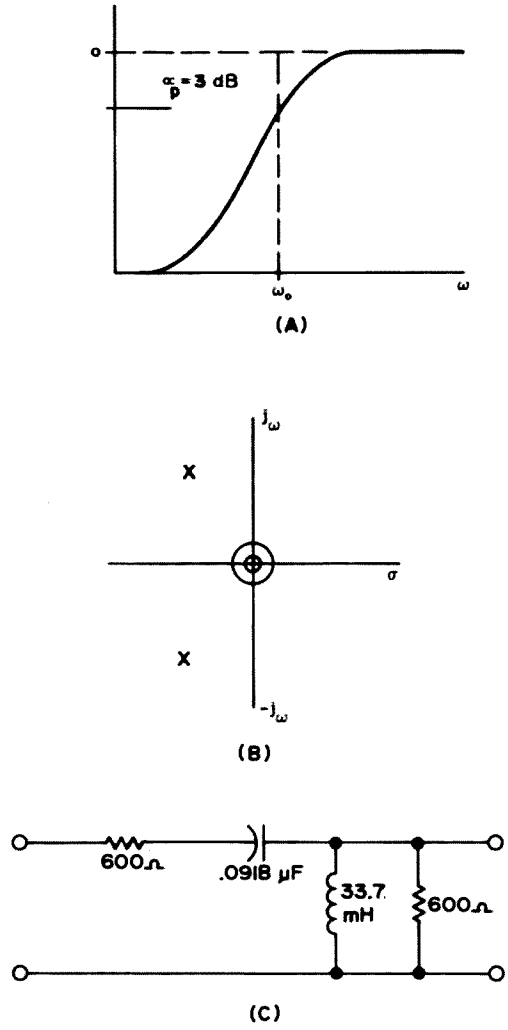

Fig. 2. High-pass filter.

task of great complexity and more suited to computer analysis. By utilizing a complex plane with theoretical component values plotted in complex impedance form, a pole-zero plot of the filter is made. Figures 1A through 4A show the pole-zero plots for four simple filters of different types. Since current/voltage node values are necessary to determine the resulting waveform, this design procedure does not lend itself to amateur filter construction.

Although active filters do away with inductances, in order to simulate the desired response, they must provide the same basic parameters as the coils in the passive filters. The main difference in operation is the ability to increase the Q, or gain of the active filter. In addition, the active filter can be designed so that changing input/output impedances, as a result of tuning internal or external circuits, has little or no effect on filter response. To better understand how filter design is fitted to the desired frequency response, we should begin with basic passive filter types.

In the design of the low-pass filter shown in Fig. 1, we begin by specifying the desired parameters. If we desire a filter with less than 1 dB attenuation from 0 to 2 kHz, and more than 20 dB attenuation above 7 kHz, with 600Ω input/output impedances, we must first determine the bandwidth ratio:

$$y = \frac{7\ \text{kHz}}{2\ \text{kHz}} = 3.5$$

The attenuation ratio of Butterworth response filters is given as:

$$A = \sqrt{1 + \omega^{2n}}$$

Where $\omega = 1$ radian per second, any value of n, or number of poles, will give an atten-

uation ratio equal to $\sqrt{2}$. Naturally, substituting other values of frequency for ω will provide a passband attenuation for Butterworth filters. By computing these various frequencies with different values of n, we can obtain a simulated response shape for filters with various numbers of poles. A two-pole Butterworth filter provides 0.93 dB attenuation at 0.7 of the cutoff frequency of 2 kHz.

As the frequency component of ω becomes higher, the attenuation increases. Similarly, as the number of poles increases, so does the filter attenuation, thus creating a sharper stop-band cutoff. At 3.15 of the cutoff frequency, the stop-band attenuation of a two-pole Butterworth filter approaches 20 dB. A reevaluation of the bandwidth ratios gives:

$$y = \frac{3.15}{0.93} = 3.39$$

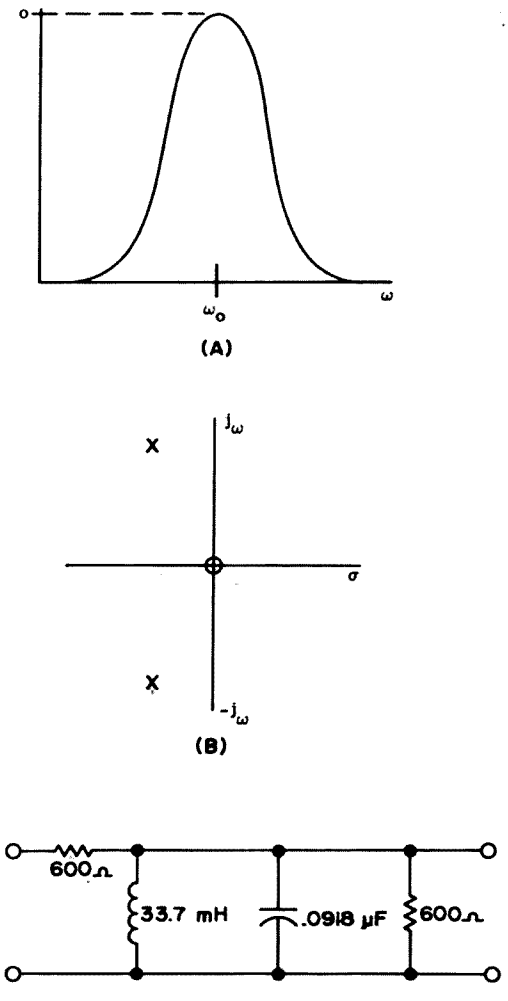

Fig. 3. Bandpass filter.

Since this performance is better than our specified ratio, all requirements can be met with a two-pole Butterworth design. To preclude otherwise necessary computations involving resonant frequencies and cutoff formulas, we can design by means of a normalized prototype. A low-pass prototype is normalized for 1Ω terminations and a cutoff of 1 radian per second. From these values, as shown in Fig. 5, the resistances/impedances and cutoff frequency must be altered to fit our specifications. By means of impedance scaling, we can alter the resistances to allow the filter to operate between terminations of any value. Impedance scaling does not affect filter response, and is accomplished by simply multiplying

all resistances by the desired impedance value, 600Ω in this case. In order to adapt the normalized cutoff frequency to 2 kHz, we employ frequency scaling. Frequency scaling leaves all impedances unchanged but applies a constant to the reactive elements. In scaling the inductance to the required filter value, the following formula is used:

$$L' = \left(\frac{R'}{R}\right)\left(\frac{\omega}{\omega'}\right) L$$

Where the primes denote values after impedance scaling.

Substituting the filter values in this formula gives an inductance constant of:

$$= \frac{(600)\quad(1)}{(1)\ (2\pi \times 2\text{x}10^3)}\ L$$

$$= 47.71\text{Lx}10^{-3}$$

This computed value is the inductance constant in millihenrys. Applying this constant to the prototype gives:

$$(47.7\text{x}10^{-3})\,(1.414) = 67.5\ \text{mH}$$

In scaling the capacitance to the required filter value, the following formula is used:

$$C' = \left(\frac{R}{R'}\right)\left(\frac{\omega'}{\omega}\right) C$$

Substituting the filter values in this formula gives a capacitance constant of:

$$= \frac{(1)\quad(1)}{(600)\ (2\pi \times 2\text{x}10^3)}\ C$$

$$= 0.13\text{Cx}10^{-6}$$

This computed value is the capacitance constant in microfarads. Applying the constant to the prototype gives:

$$(0.13\text{x}10^{-6})\,(1.414) = 0.184\ \mu\text{F}$$

The completed filter is shown in Fig. 1C.

Highpass filter design is simplified to the extent that the response requirements can be applied to low-pass filters by inversion of the high-pass requirements. Thus, if we change the positions of the inductor and

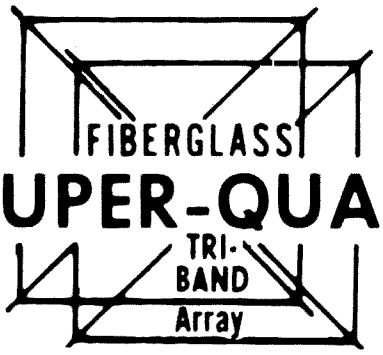
capacitor in the low-pass filter just completed, and replace the element values by their reciprocals, we have a prototype for the high-pass filter. By utilizing the same specifications, the low-pass response can be used as high-pass response by allowing the attenuation to remain as is and treating the frequencies as reciprocals. Figure 6 shows the resulting prototype for specifications similar to the low-pass filter, and Fig. 2C gives the end values.

Normal bandpass filters are symmetrical about a center frequency. Figure 7 shows the bandpass response with shape parameters. Once again the design process is simplified by utilizing a suitable low-pass design. If the value of Q is correct, the bandwidth will be the same for the low-pass and bandpass filter. The required value of Q is given as

$$Q_C = \frac{f_o}{B_3}$$

If, for simplicity, we use the original low-pass requirements, we obtain a value of Q_C:

$$Q_C = \frac{1 \times 10^3}{2 \times 10^3} = 0.5$$



This low value of Q is not typical for a bandpass filter, but is due to the simple requirements on the original low-pass filter and serves to show the necessary calculations.

Having chosen a suitable low-pass prototype, it must be frequency scaled to the cutoff frequency ω_C:

$$\omega_C = \frac{1}{Q_C} = \frac{1}{0.5} = 2$$

Due to the fact that the bandpass filter will be resonated at $\omega_O = 1$, the LC components must have reciprocal numbers. Referring to the calculations for the high-pass filter, it will be noted that the prototype element values for this filter were also reciprocals of the low-pass elements. In designing the high-pass filter, we need only transform the values of the low and high-pass filters. The cutoff frequency (the highest frequency at which maximum attenuation occurs in the passband) of ω_C in the low-pass filter becomes f_2 (Fig. 7) of

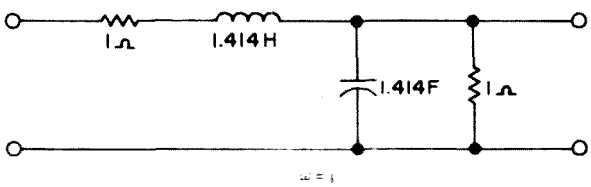

Fig. 5. Low-pass filter prototype.

the bandpass waveform. Similarly, the cutoff frequency of ω_c for the high-pass filter becomes f_1 of the bandpass waveform. In order to maximize the waveform at f_0, we need the least amount of attenuation at this frequency. The simple bandpass of Fig. 3C will be recognized as nothing more than a parallel resonant circuit at f_0. To increase the attenuation on either side of f_0 (narrow the passband), we must either increase the gain or the Q. When using RLC circuits, we can only decrease R as far as possible and increase Q to maximum. As the frequency of interest becomes lower, higher values of Q become increasingly more difficult to achieve.

In order to achieve a smaller bandwidth in passive circuits, we must increase the number of filter sections used. When such an increase is necessary, the insertion loss is raised. Designing with active RC filters solves these problems by first of all removing the inductance. This solves the problem of stray coil capacitance, low Q at low frequencies, and mutual coupling between coils.

The bandstop filter of Fig. 4 can also be considered as a combination of the low-pass and high-pass designs, with the transformation utilizing the reciprocals of the bandwidth ratios used for the bandpass design. If we remove L_2 and C_1 from the design of Fig. 4C, we are left with a low-pass filter and a high-pass filter. As noted, transformations of an adequate low-pass design are possible; however, to

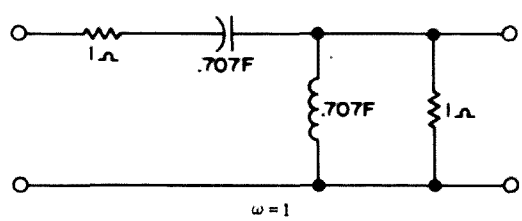

Fig. 6. High-pass filter prototype.

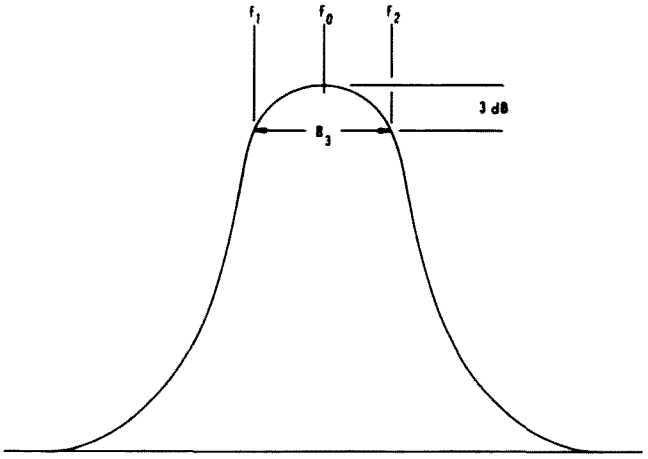

Fig. 7. Bandpass response parameters.

preclude degradation of performance, additional measures are sometimes necessary. In the bandstop design we have paralleled a high-pass and a low-pass filter. Once the input and output terminals of these filters are common, the impedance value of the original filters is no longer 600Ω. Consequently, the response shape of the filter is nearly unrecognizable. To prohibit loading of the circuit, each filter must have a high impedance in that portion of the circuit which produces an overlapping response with the other filter. Otherwise, the best response that could be expected would appear like the dotted line in Fig. 4A. Inserting a component presenting a high impedance in the series branch of the input or output of each network will serve to separate the filter responses. In the case of the low-pass section, we already have an inductor in the series branch of the input, so another coil is added to the output branch. In the high-pass section, the output branch is already coupled by a capacitor, so we add a capacitor to the series input branch.

Since we will be working with amplifier stages in the design of active filters, the same requirements to asssure stable operation at needed gain are valid. Consequently, the first parameter to be specified for an active filter should be necessary gain. Unfortunately, we cannot simply say a gain of 10 dB is necessary between input and output terminals, as we might be able to do with a normal amplifier stage. Because we have removed the inductors from the passive network, we must substitute a method of obtaining complex values for poles and zeros in order to simulate the required waveform. Phase shifts become more important and feedback is necessary to match impedance, stabilize the filter, increase gain, or a combination of these. As in the design of any circuit, tradeoffs must be made for optimum operation. The overall active network exhibits a value of sensitivity which affects its operation. Networks employing positive feedback are subject to oscillation, which might be created by element variations in a Q-sensitive circuit. Negative feedback tends to decrease the gain to unity, but nearly eliminates the Q sensitivity. Gain is directly related to the input/output impedance ratio. This level may be changed by appropriate resistance; however, the optimum dc current value must not be lowered in the process. Choosing high-gain transistors (minimum beta of 150) will allow maximum circuit alteration to achieve the desired response without making the circuit unstable.

Figure 8 shows a two-pole active filter incorporating positive feedback. In addition to the fact that C1 provides positive signal feedback to the first amplifier, it also acts as a complex zero function without a direct ground reference. Consequently, a change in device parameters caused by temperature or impedance may allow this "floating" zero function to alter its position in the frequency plane, thus distorting the desired filter waveshape. If we consider Amplifiers A1 and A2 as transistor stages, Fig. 8 would show them them connected in a common emitter configuration. However, changing the output points of each stage to the emitter will provide a network with unity gain, low Q and freedom from

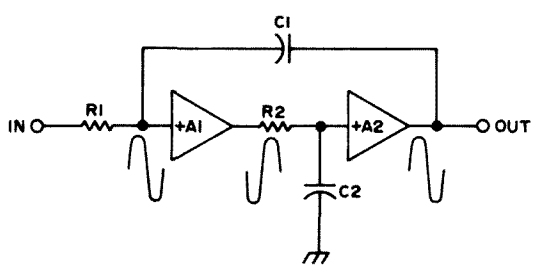

Fig. 8. Active filter with positive feedback.

possible oscillation. In such a configuration, a large ratio of component values will be required and the source must be a current amplifier.

Figure 9 shows a high-gain operational amplifier utilizing a twin-tee network to provide negative feedback. This network operates as a bandpass filter, thus requiring high Q and gain. The inherent high gain of the operational amplifier allows the filter shape, or Q, to remain insensitive to changes in amplifier level. The required ratio of network values in this design is low, but the parameters are difficult to adjust due to the number of elements required. Figure 10 shows the same type of active filter using two operational amplifiers. This circuit incorporates resistive damping to preclude operation as an oscillator. A minimum number of components are necessary and the filter adjusts easily. A constant-current source assures freedom from impedance loading which might affect the filter response.

An additional advantage of inductorless RC networks is the possibility of temperature compensation. A positive temperature coefficient exhibited by a resistor can be offset by a negative temperature coefficient capacitor.

There is virtually no comparison in physical size between the passive and active networks. This becomes most evident when comparing low frequency filters using large iron core inductors, to integrated circuit networks. The small size is further enhanced due to the fact that shielding and physical separation of components to preclude mutual coupling is of minimum importance in most active filter designs.

Component specification problems are considerably eased without having to worry about coil problems. Depending on the circuitry chosen, Q and bandwidth are varied by either resistors or capacitors. The tolerance of these components is usually within 10% and the capacitors should have reasonably good thermal stability. Active networks utilizing transistors will require biasing resistors in addition to the frequency compensating components. Operational amplifiers will require a minimum of outboard components for frequency compensation. An overall comparison of cost between the passive and active networks is hard to make. At the lower frequencies, the active networks are much cheaper to design and construct due to the cost of heavy inductors used in the LC circuits. At the higher frequencies, cost is somewhat dependent on performance, but there is never a time when cost is prohibitive. Normally, component costs for the active filter more than compensate for the problems and labor required in design and construction of inductor filters.

Performance of the active filters surpasses that of the passive networks at the lower frequencies, and more than equals them at the higher frequencies, all with the main advantage of doing away with the many problems associated with inductors.

ANTENNA PARTY

Or, raise your own antenna and eat the goodies yourself.

As soon as I can afford a tower, I'm going to put up a beam." How often have you heard or said that very thing? Pull up a shovel and sit down and relax a moment, while I describe an economical antenna tower you would be proud to erect.

First, scout around the community for a tall telephone pole . . . then at night . . . no, that won't work. On second thought, go to the telephone or power company and ask if they are planning to take down any poles in the near future. Tell them you would like to have one so you can erect an antenna to assist in disasters or tracking tornadoes – public service, you know. For a small fee they may deliver, dig a hole, and set the pole for you. We have dreamed long enough, so let's get down to copper tacks and go to work.

Prepare the pole before setting it by sawing the top off straight so the saddle (Fig. 4) will bolt on properly. Drill the holes for the saddle and install it. Drill pilot holes alternately on each side of the pole for large lag screws to be installed for steps. You may have a desire to climb it for one reason or another. The view is certainly nice from up there. Be sure the steps are positioned so they will not interfere with the drive shaft.

Set the pole so the top of the saddle is as level as possible. To accomplish this you can eyeball it, use a plumb bob or a level. A 40 or 50 ft pole should be set in the ground approximately 8 ft. Install 5/8 in. lag screws for steps, and now you're ready to do some measuring and locating of components on the pole.

Saddle Construction

To determine the length of U-channel required and how much overhang is needed, one must first determine how far the drive shaft will be from the pole. This will be dependent upon the rotator and mount

position. A piece of 4 or 6 in. iron U-channel may be utilized for the saddle. Cut the end on each side as shown in Fig. 1, and then bend the end down and weld as shown in Fig. 2.

Fig. 1.

Fig. 2.

Obtain two narrow sturdy pulleys and a steel rod for axles. Cut the slots for the sled and pulleys as shown in Fig. 3. Install pulleys in the slots and weld or bolt axles to the underside of the U-channel. Drill a ½ in. hole near the center of the U-channel for lag screwing into the top of the pole.

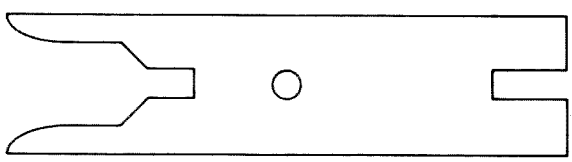

Fig. 3.

Weld a short piece of ¼ in. steel rod next to the pulleys and bend them over the pulleys to prevent the steel cable, when installed, from jumping out of the pulley grooves. Cut and weld a 16 in. piece of U-channel to fit inside of the saddle as shown in Fig. 4, so the center of the sled slot is the same distance from the pole as the center of the rotator drive assembly. The taper of the pole may have to be considered so the drive shaft will be perpendicular when installed. Drill a 5/8 in. hole approximately 6 in. down from the top and another hole approximately 14 in. from the top. Before installing the saddle, make the sled to fit the saddle-sled slot without binding.

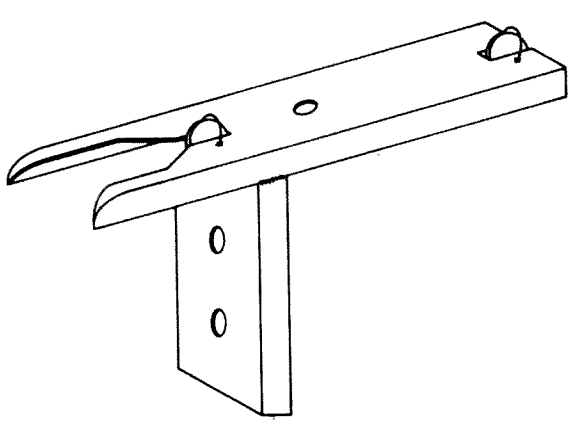

Fig. 4. Saddle assembly.

Sled Construction

The base of the sled is constructed from 1/8 in. steel approximately 7 in. long and approximately as wide as the U-channel. Cut a 2 in. hole near the center and bend the front as shown in Fig. 5. Drill a 3/8 in. hole in the center at each end approximately ½ in. from the edge.

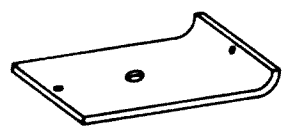

Fig. 5. Sled.

Using 1 in. strap iron, bend it to fit the shape of the slot in the saddle as shown in Fig. 6.. Weld this guide to the bottom of the sled as shown in Fig. 7. Be sure it is positioned so the drive shaft will be vertical.

Visit a salvage yard and purchase a thrust bearing that will slip over a 1¼ in. pipe. The thrust bearing is used to carry the weight of the antenna system on the saddle and not on the rotator, plus allowing ease of rotation. The thrust bearing is not required if these features are not desired. Position the thrust bearing on top of the sled and over the hole so the drive shaft can be inserted through both assemblies. Weld the outer race of the bearing to the sled so that when a load is placed on top of the bearing it will be free to rotate. This completes the sled construction.

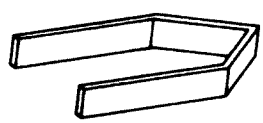

Fig. 6. Guide.

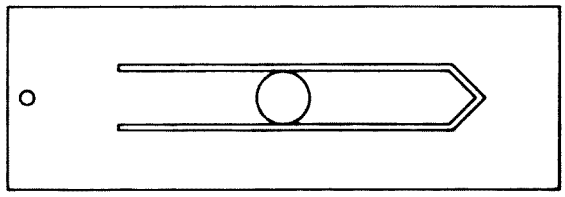

Fig. 7.

Drive Shaft Bracket

The drive shaft L-bracket stabilizes the hinge point during rotation and lowering of the antenna. A 4 in. wide and approximately 12 in. long piece of 1/8 in. steel should be bent into an "L" shape. The hole in the bracket for the drive shaft can be measured and cut after the drive shaft is temporarily installed, to make it easier to locate the exact position for the hole. The drive shaft is then placed through the hole of the bracket. The bracket is positioned just below the hinge point and then lag screws are used to fasten it to the pole. The hinge point cannot be determined until the antenna height above the pole is known. The antenna height above the pole can be 10 ft or greater depending upon weight and wind load of the antenna. The hinge point will be approximately halfway between the antenna and the ground. The length of the lower portion of the 1½ in. drive shaft is from the rotator to the hinge point and the upper portion from the hinge point to the antenna.

Hinge Construction

Cut two pieces of 1½ in. pipe, 24 in. long. Drill a half-inch hole, 3 in. from one end, through each piece. Drill another half-inch hole, 9 in. from the same end. These holes have to be drilled accurately, so half-inch bolts can be inserted through both pieces. It is suggested that when one hole is drilled through each, they be bolted together before drilling the second hole. This will assure alignment of the two pieces. Two similar holes must be drilled in the lower drive shaft and these must be drilled accurately so all three pieces can be bolted together as shown in Fig. 8.

Weld the two pieces to the upper portion of the drive shaft or bolt them together if desired. In either case, keep the lower section bolted together to assure alignment

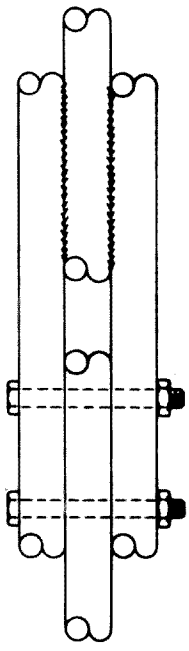

Fig. 8. Hinge assembly.

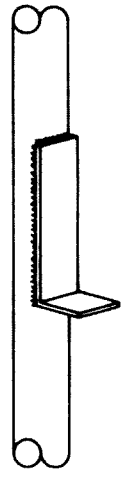
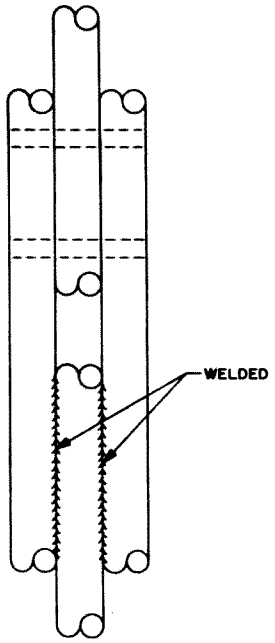
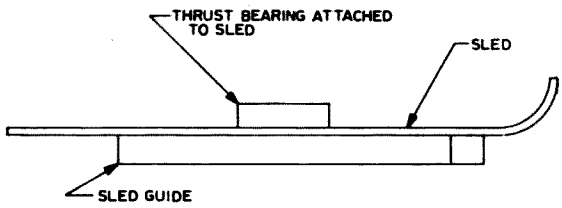
when completed. It is suggested that a washer be installed to allow ease of removal of the lower drive shaft after the welding operation. Removal of one bolt will allow the drive shaft to hinge on the other bolt. Two bolts are used for added strength.

The upper drive shaft is inserted through the sled assembly, winch installed on the pole, and ¼ in. steel cable run from the winch up over the two pulleys on the saddle and down to the ground, where it is attached to the front of the sled. Insert the lower drive shaft through the center bracket and attach the other end of the drive shaft to the rotator. Hoist the upper drive shaft so the







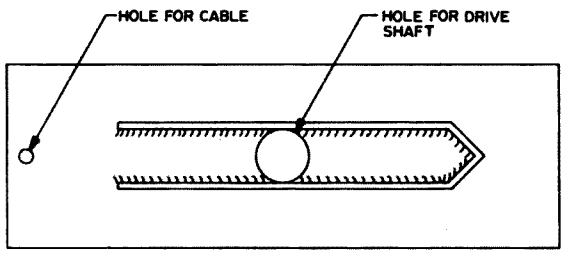


Fig. 9.

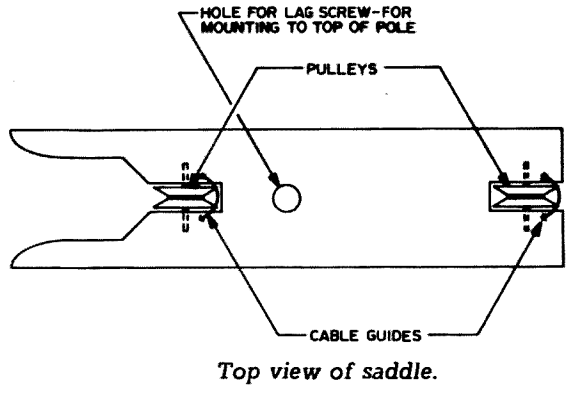
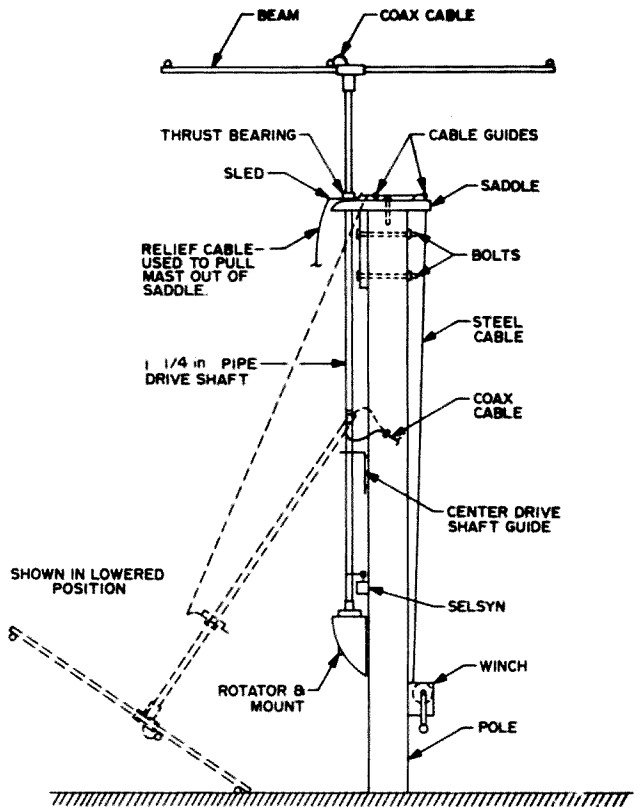


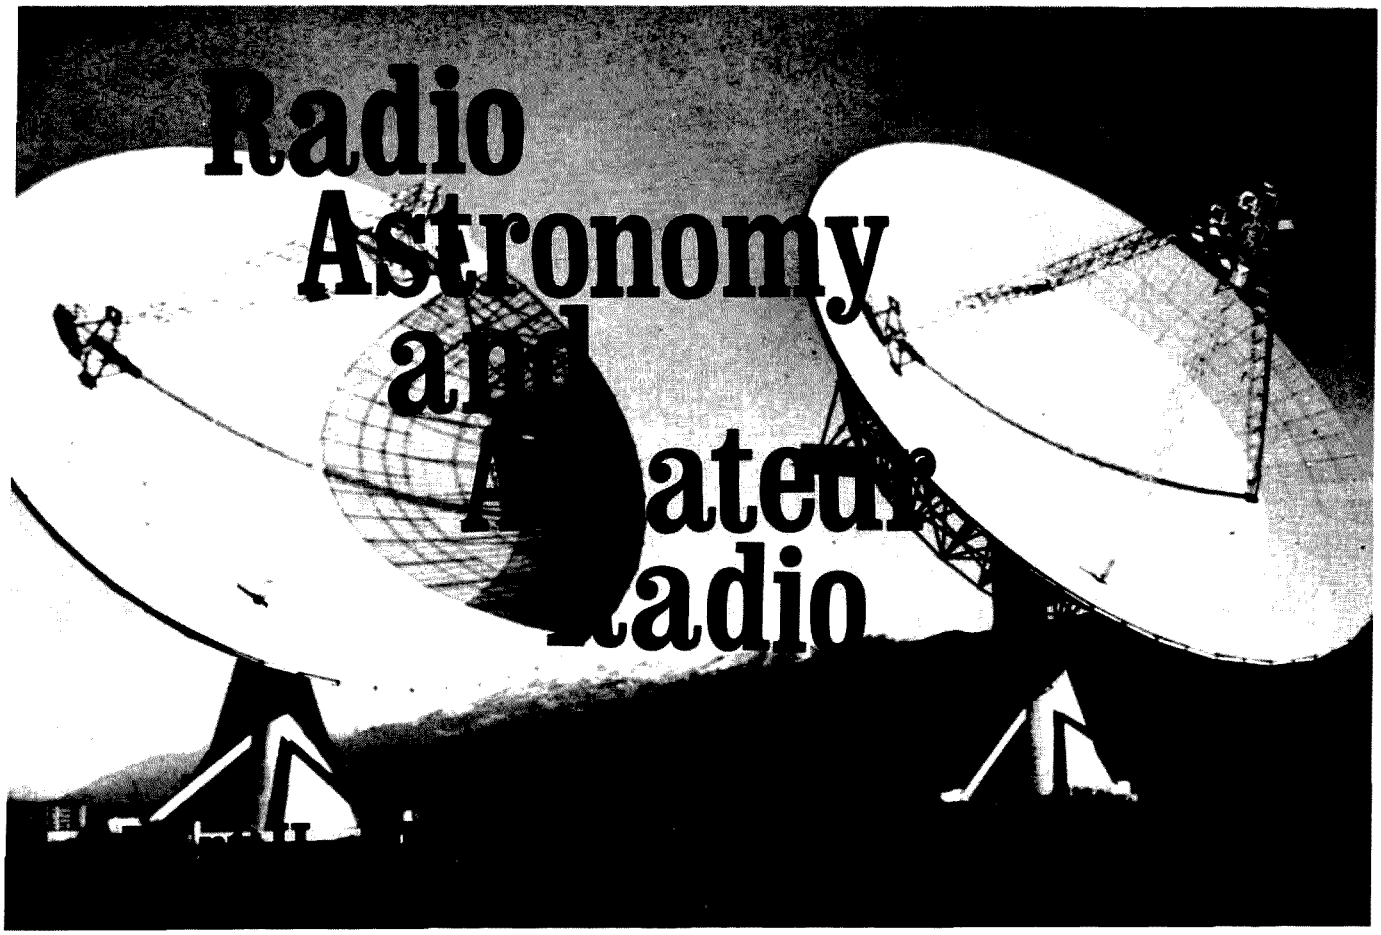
Hinge portion of driveshaft.



Side view of sled.

Bottom view of sled.

Top view of saddle.



The whole shebang.

Fig. 10.

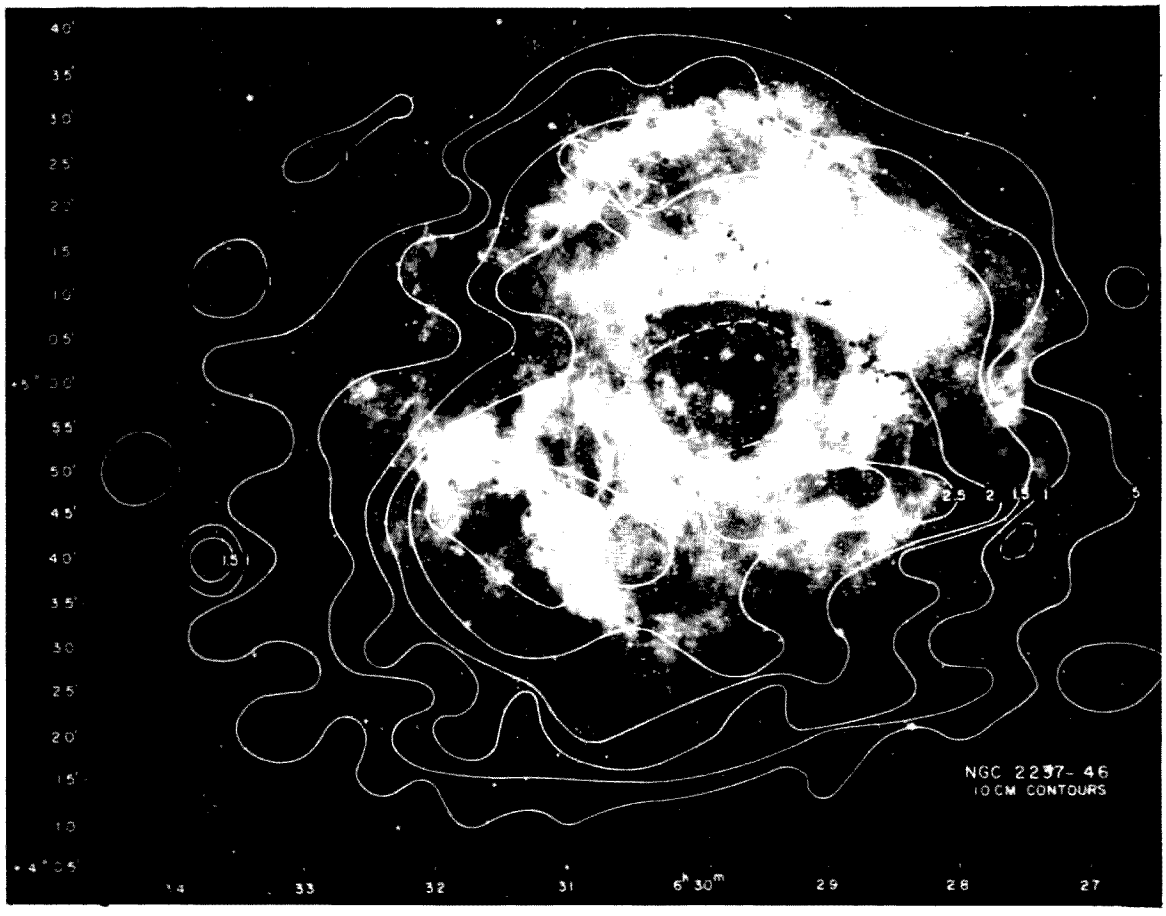
hinge section can be mated by inserting a bolt. After drive shaft and sled are hoisted to the operating position, install center bracket and mark the pipe even with the top of the thrust bearing. Lower upper section and weld inner race of thrust bearing to the pipe a small fraction of an inch below the mark, so the weight will be carried by the bearing and not the rotator when in operating position. Attach antenna and route cable down center of pipe and out of the hinge. Provide sufficient slack in cable to allow for more than 360° of antenna rotation. A reversing switch can also be installed, or a limit switch, if desired. Be sure to install a good ground system. I have used this type of system for over ten years at two different locations without one speck of trouble. More recently a Cliff Dweller antenna was installed above the TA-33 Tri-band Mosley beam with excellent results. No guy wires clutter up the yard, and antennas can be lowered and raised single-handedly. It is suggested that a piece of strap iron as shown in Fig. 9 be welded to the pipe where the antenna attaches with U-clamps. This will prevent the antenna from rotating on the pipe or slipping down the pipe if it should loosen.

. . .WØBMW

Radio Astronomy and Amateur Radio

Ed. Note: The first half of this two-part series contained figures numbered 1–4. Hence, in this section, which is a logical continuation from Part I, the figures are numbered sequentially from 5 to 8.

The radio spectrum extends up to about 40,000 MHz, and is grouped into seven classifications because of the vast differences throughout the total radio frequency spectrum.



10–30 kHz Very low freq.
30–300 kHz Low freq.
300–3000 kHz Medium freq.
3–30 MHz High freq.
30–300 MHz Very high freq.
300–3000 MHz Ultrahigh freq.
3–30 GHz Superhigh freq.

If the radio spectrum were a yardstick, the first 10 in. would contain 98% of all radio communications used for military, aviation, radar, two-way radio, ship-to-shore, ham radio operations, mobile telephone, AM broadcasting, FM broadcasting, international broadcasting, VHF television, and UHF television broadcasting.

It would seem that the last 25 or 30 in. of the yardstick or 25–30,000 MHz would be the best place for observing with the radio telescope. But at frequencies above 3000 MHz it becomes a major problem to reduce noise coming from the source in space.

While the problem at superhigh frequencies is atmospheric absorption, at lower frequencies the ionosphere reduces the signal level of waves passing through the charged layer. In addition, this layer in the upper atmosphere can cause signals at low angles to skip back into space just as radio signals on the reverse side are bounced back toward the earth.

The upper layers of the atmosphere (Fig. 5) form thick layers or bands of ionized particles when these atoms are excited by ultraviolet energy from the sun. Obviously, while thick bands of ionization are formed during the day this same upper

The Rosette nebula – a radio stellar source observed at the 10 cm wavelength or about 3000 MHz. The white lines outline the radio contours and are superimposed on an optical telescope photograph of the Rosette nebula. Numbers along the base of the photograph are known as right ascension (RA), which together with the declination angle along the left side of the photograph give the astronomer the exact position of the source on the celestial sphere. NGC-2237-46 located in the lower right corner indicates the new general catalog number of the source. This was a list of optical star clusters, nebulae, and galaxies compiled in 1888. The cataloging of sources is a must in order to let astronomers locate sources quickly. This particular nebula is relatively young and hot; notice how the areas of intense radio energy correspond to areas of intense visual light. (National Radio Astronomy Observatory.)

rather than an audio signal varying at an audio rate. This varying dc drives a pen which is set in a movement very similar to a meter movement. A change in voltage causes the pen to swing in the same manner as the needle of a voltmeter.

If the variations of the pen follow each small change of input, the final product will end up being a mass of confusion so some way must be used to smooth out the rate of pen movement. The exact rate depends on the type of observation being made. Normally a capacitor and resistor are placed in the pen circuit to even out the fluctuations. (See Fig. 8.)

Another important stage in the telescope is the noise generator, which provides a calibration source of a known intensity, for plotting relative intensity and actual intensity at the receiver.

Types of Radio Telescopes

Telescopes may be either of the radiometer type or of the interferometer type.

The radiometer is a simple single radio telescope used to observe radio sources much like an optical telescope.

An interferometer consists of two or more antennas which are used in conjunction with each other. If two antennas are used they both feed a single receiver.

The use of two antennas as in Fig. 8 actually increases the effective aperture of the telescope; thus much more resolution can be built into a receiver without making it physically larger.

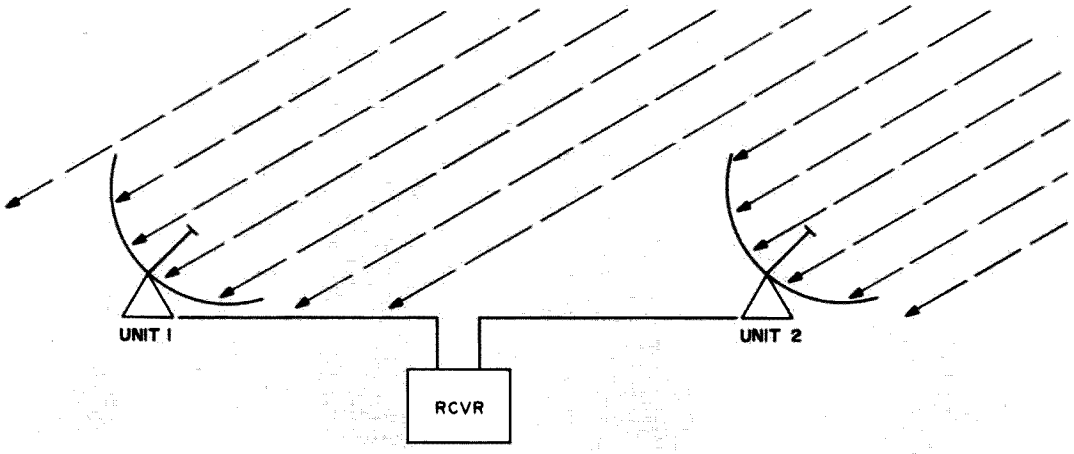


Fig. 8. Energy from space arrives at telescope 2 first, causing a phase differential between the two antennas; this "difference" is useful in determining astronomical data.

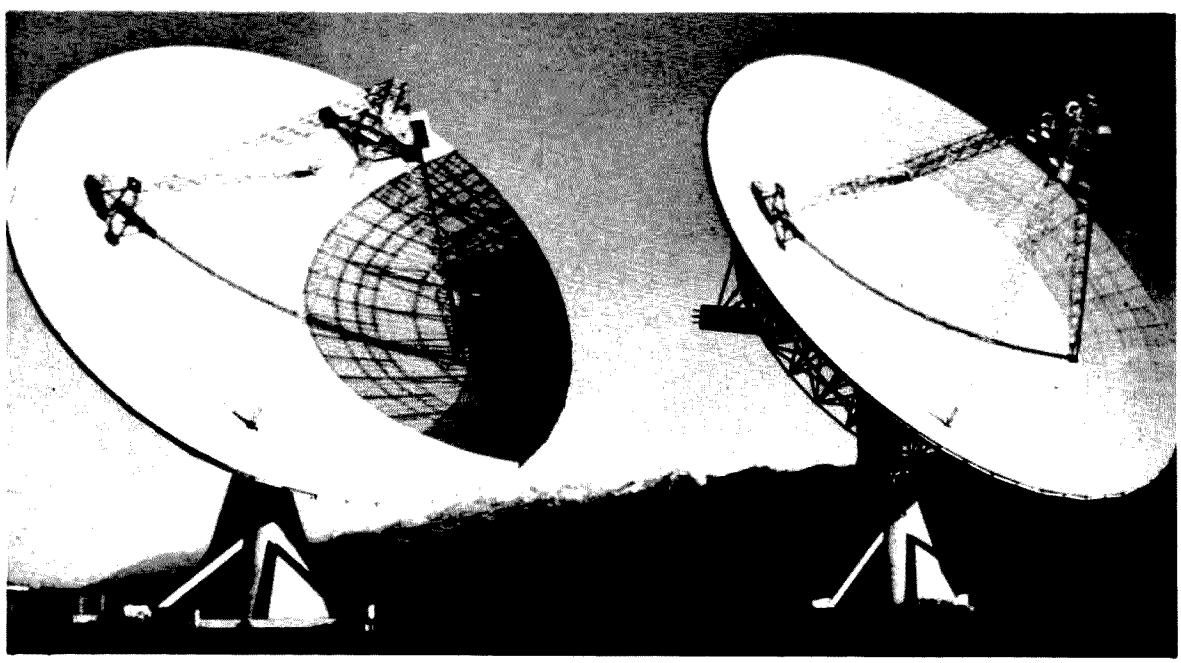

Antennas

One of the most important factors in the performance of a telescope is the antenna. The antenna of a dish type telescope does the exact same job as a mirror of a reflecting-type optical telescope. It gathers energy and focuses it to a specific point.

Parabolic. The dish is not the only antenna being used for radio astronomy; in many cases the dish is the most inefficient antenna which might be selected. For example, because a dish needs to be at least 10 wavelengths in diameter, at wavelengths longer than 20 meters a movable antenna becomes almost impossible even for the professional with unlimited funds.

The dish is a broadband device with a rather flat gain curve over several megahertz. It is important to be broadbanded for most radio astronomy applications. It does no good to have a broad intermediate frequency if the antenna has a sharp gain response.

The higher in frequency one goes with the same size dish antenna the more efficient the antenna will perform. This is because the higher the frequency the shorter the wavelength: The wavelength (λ)

Twin 90 ft telescopes at Owens Valley Observatory operated by the California Institute of Technology through funds provided by the Office of Naval Research. (Office of Naval Research.)

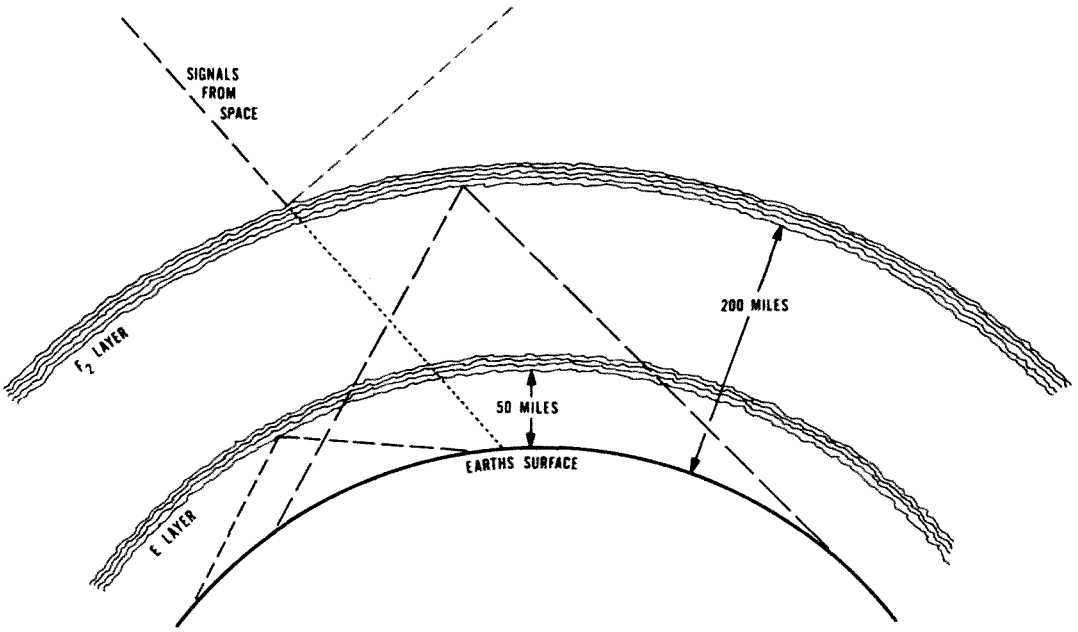

Fig. 5. The E and F ionosphere layers reflect signals from space as well as signals from earth.

atmosphere is transparent to medium and high radio frequencies during the night.

The ionosphere is not one solid layer but consists of a series of layers at different heights above the earth's surface.

At a height of about 70 miles, the first ionized layer (E) exists. The second layer consists of a single layer of ions during the night but splits into two separate layers during the day. The average height of the F layer is 175 miles.

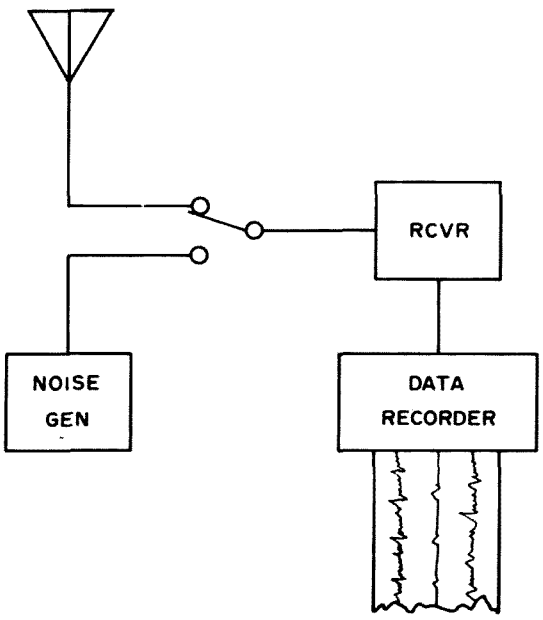

Fig. 6. Simplified data gathering system consists of a noise source, receivers and antenna, and a method for recording the incoming information.

The Basic System

Almost all radio telescopes in use today consist of an antenna, receiver, data recorder, and noise generator for calibration.

Figure 6 shows a block diagram of a simple system.

The receiver operates on the standard superheterodyne principle not too unlike a standard home television set.

An expanded telescope is diagrammed in Fig. 7. Note that the various stages of the receiver portions are displayed in greater detail.

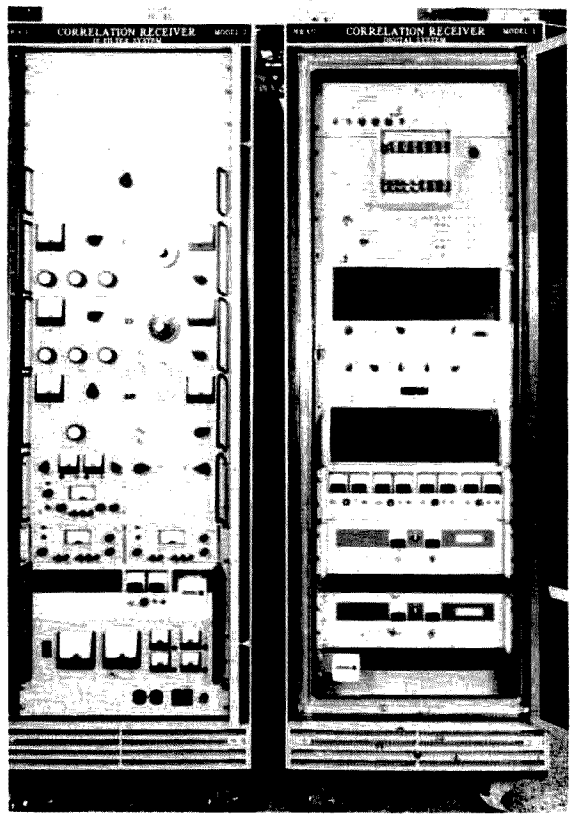
A signal is induced into the antenna and is transferred to the input of the rf amplifier stage via a coaxial transmission line. The rf amplifier is usually a broadband device with a low internal noise and 10–30 dB of overall gain. The most important function of the rf amplifier is to establish a low noise level throughout the system. It is obvious that excess noise generated in this stage will be fed back and amplified along with the desired signal in each of the succeeding amplifier stages of the receiver.

The next stage after the rf amplifier is the mixer. This stage along with the oscillator combine to lower the output frequency to the intermediate frequency.

The oscillator is removed in frequency from the carrier frequency by a difference

of the intermediate frequency. The oscillator can be made to operate either above or below the carrier frequency but always the difference must be that of the intermediate frequency.

This stepdown in frequency is the heart of the superheterodyne principle for it is easier to attain high sensitivity, selectivity, and stability at the lower frequencies than at the higher ones.



Just as the rf amplifier determines the noise level of the entire receiver, the i-f amplifier determines the sensitivity and selectivity of the entire telescope. The i-f amplifier is usually made up of at least 2 or 3 amplifiers; and 30 to 120 dB in total gain is the norm. The bandwidth depends on the type of signal the observer wishes to receive. If some discrete narrowband signal is being received the bandpass of the i-f amplifier must also be narrow. Such a signal might come from a spacecraft or satellite.

For natural radio noise a wide bandpass must be used, on the order of 3–6 MHz. At lower frequencies it is almost impossible to find 3 MHz with no other man-made radio signals which would interfere with the observation. As a consequence, the radio astronomer must be content with only a few kilohertz of bandpass at frequencies below 100 MHz.

After the i-f stage has amplified the signal and established the receiver's bandpass, the signal is sent to the detector stage, where the i-f is blocked by a diode, leaving only the variations which appeared on the original frequency.

After the detector, the signal is sent to either an audio frequency amplifier if the receiver output is a speaker or a dc amplifier if the final output is to be a pen recorder.

If a pen recorder is used a dc amplifier is needed to convert the signal to a varying dc

This unique receiver was designed and built at the NRAO and is used for receiving spectral lines of elements which fall within the radio spectrum. The i-f amplifier is contained within the rack on the left. The i-f stage is the first stage inside the "shack"; this is because the rf amplifier and mixer stages are mounted out at the antenna. Several narrowband filters are located in the i-f stage to allow for a very accurate determination of frequency. The rack on the left contains the digital switching system, a memory bank, and various power supplies. (National Radio Astronomy Observatory.)

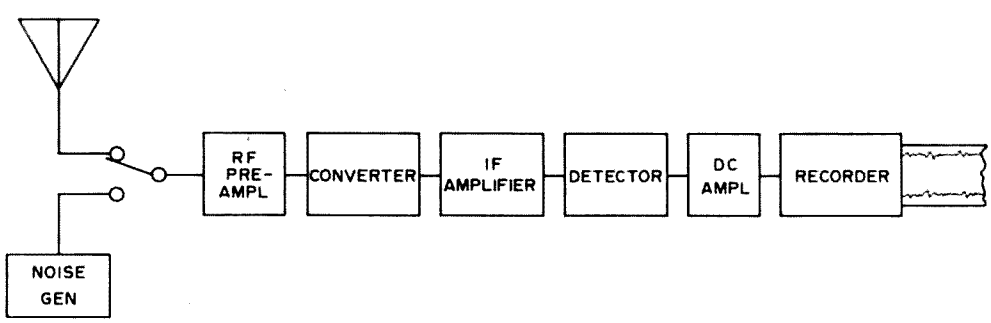


Fig. 7. Block diagram of a complete radio telescope system.

THE VANGUARD FREQUENCY SYNTHESIZER

- 1000 channels from one crystal (yes, that's one thousand) selectable every 10 KHz. from 140.00 to 149.99 MHz.
- Better than .0005% (5 parts per million) from −10° to +60° C down to −30° C with accessory heater available later.
- Thumbwheel switches with digital readout for fast selection.
- Uses a super precision crystal reference source operating at 5 MHz. for easy checking with WWV. RF output is obtained from a VCO tightly locked to the reference source in a digital phase-locked loop circuit.
- Present model is available with output in the 6, 12 or 18 MHz. band (corresponding to 144 MHz.) for direct substitution of transmitting crystals. Built-in computer selects the appropriate frequency when you set the readout to the transmitter output you want.
- Changes frequency almost as fast as you can switch. Settling time is in milliseconds even when switching from one band limit to the other. No hunting or false locks as with some other synthesizers.

"YOU'LL NEVER HAVE TO BUY CRYSTALS AGAIN"

MODEL ST-140. Size: 1 3/8" high x 3 5/8" wide x 8" long.
PRICE: $119.95 ppd.
NOTE: NY State residents add sales tax.

- Operates from 10 to 15 VDC. Includes 3 precision IC voltage regulators (one for each major circuit function) to prevent interaction and to take care of those wide voltage swings in mobile installations. Can also be used on 110 volts AC with a small 12 volt 1/2 amp power supply. 50 ohm output for remote operation.

COMING SOON: A frequency synthesizer for 45 MHz. receive crystals, a combination transmit and receive synthesizer, a synthesizer with direct output in the 144 and 220 MHz. band, and a whole series of synthesizers to cover from sub-audio to microwave frequencies.

IMPORTANT: When ordering be sure to state if you want the 6, 12 or 18 MHz. output.

VANGUARD LABS

196-23 Jamaica Ave.
Hollis, N.Y. 11423

is equal to the frequency (f) divided by the speed of light (c).

Collinear. The collinear (phased array) antenna is definitely an "up and coming" antenna. The need for phased-array antennas has come about as a result of the need to track high speed missiles at close range, where it becomes impractical to turn the antenna mechanically. Many satellite tracking antennas as well as the ABM radars are of the phased-array type. During the 1950s and 1960s parabolic (and parabolic derivative) antennas were used. The first radar signals bounced off of the moon were made using a phased-array radar antenna.

Phased arrays like the parabolics are broadband antennas. Unlike the parabolic, which must be built to close tolerances, the phased array is not particularly critical.

Yagi Beams. Very high gains can be had with this antenna; however, it has one serious drawback: As the elements are added to achieve more gain, the frequency response is narrowed. This is not a real problem at frequencies below 30 MHz; however, at VHF and higher a yagi with the same gain as a collinear or parabolic would have a bandwidth of less than 1 MHz, which would impose serious limitations on performance. A parallel would be an optical telescope with both ends of the visible light spectrum filtered out.

If one specific narrowband signal were to be observed, such as a weather satellite, a yagi would be a superior antenna because interference several megahertz removed would be partially filtered out by the inefficiency of the yagis at those frequencies.

The yagi itself consists of one driven element and several parasitic elements. A longer element in back of the dipole serves as a reflector. Shorter elements in front of the driven element serve as "directors."

Helix Antennas. A quite popular antenna for telemetry and weather satellite acquisition is the helix. The helix is a compromise antenna. For a given size and cost the helix is slightly less efficient than the other antennas already described. However, it is extremely broadbanded and will receive signals polarized horizontal, vertical, or circular.

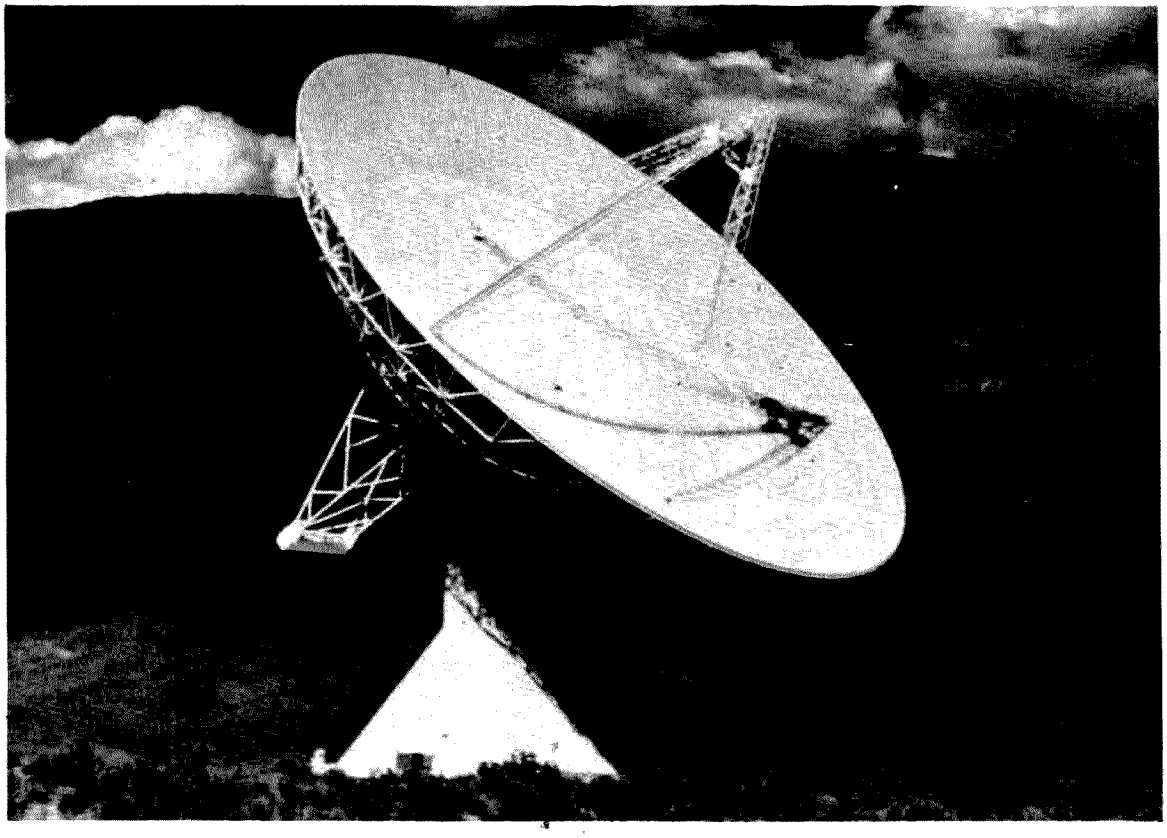
In a yagi which is polarized vertical or horizontal (depending on the position of the dipole), a loss of 2 dB occurs when a signal is received which is opposite in polarity from the receiving antenna.

A helix overcomes this loss even if the antenna itself does not have as much total gain as the yagi.

Problems the Amateur Can Work On

In this day of massive government spending what chance has the amateur in making a significant breakthrough? Actually, the chances are fairly good if the ham is willing to put forth some extra effort. Much listening can be done with standard ham gear; most communications receivers that cover 15 meters are capable of receiving noise from Jupiter and the sun and of hearing general galactic noise.

Some of the unknowns are:



1) How does the planet Jupiter produce its strong radio noise? Does it have something to do with the famous red spot on Jupiter?

2) How and why do sunspots usually appear on the surface of the sun at about the same time that ultraviolet energy causes changes in the ionosphere?

3) The radio observation of sun flares.

These unknowns still exist even though jovian noise, general sun noise, and sun flares may be received with relatively simple equipment; and many books, articles, and papers have been written about the subjects. Maybe, if *you* are not afraid to adventure into the unknown, it might be *you* who discovers the origin of jovian noise or the mechanics of a solar flare. The public library in section 522 has numerous books on astronomy and radio astronomy. You as an individual have the tools and much of the knowledge to again let ham radio make a meaningful contribution to science and technology.

Owens Valley Observatory 130 ft telescope operated by the California Institute of Technology through funds provided by the Office of Naval Research and the National Science Foundation. (Owens Valley Observatory.)

PATENTING YOUR INVENTION

Henry Hunter (the name is a *nom de plume*) is a lawyer and registered patent attorney. He holds degrees in both engineering and law and is a licensed amateur radio operator. **Requests for additional information cannot be answered by the author and should be addressed instead to a registered patent attorney or agent of the inquirer's own selection. See the *Directory of Registered Patent Attorneys and Agents* cited in the bibliography accompanying this article.**

Amateurs have contributed much to the advancement of the radio and electronic arts. Notwithstanding the dominance of research and development in recent years by the technical and scientific staffs of institutions, universities, and large corporations, the independent inventor has not become obsolete or even less effective. Large organizations have the advantage of funds with which to purchase equipment and the pooled talent required to utilize such most effectively, but true inventiveness – which is a more modest term for genius – is born, not bought. When God wishes man to discover more – or utilize one of – His wonders, He does not form a corporation, float a bond issue, or build a laboratory. Instead a child is born: a Marconi, a Morse, a Fleming, an Edison, or a Tesla. Although research groups and large laboratories will probably continue to pour forth discoveries and inventions, not all men of inventive talent will necessarily join their staffs, and individual inventors in small laboratories, basement workshops, and university carrels will also continue to conceive and discover a significant proportion of the inventions of the future.

While large research organizations and laboratories usually have patent counsel on their staffs or on retainer, individual inventors and smaller organizations usually do not. This article is not intended to serve that need, however, but merely to provide some general orientation and answers to certain common, general questions, and to point out the necessity of seeking competent professional advice immediately when needed.

Is Your Invention Patentable?

A United States patent may be obtained by any person who has invented or discovered any new and useful art, machine, manufacture, or composition of matter, or any new and useful improvement thereof, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any publication in this or any foreign country before his invention or discovery thereof, or more than one year prior to his application.

Patents are not granted for inventions that are useless or inoperable, for the literary content of printed matter, or for methods of doing business. Patents may be obtained, however, for designs and for certain types of plants.

Public use or sale of an invention in this country more than one year before filing a patent application, whether by or with the consent of the inventor or by another person, perhaps an independent inventor of the same idea, or perhaps one who has taken the idea without authority, will bar the grant of a patent. Additionally, use or publication of the invention in this country, before a patent application has been filed, may prevent the inventor from later obtaining foreign patents. Since it usually takes several weeks, at least, to prepare the drawings and specifications of a patent application, if an inventor wishes to apply for a patent on his invention he is usually well advised to consult his patent attorney as soon as possible after first making his invention.

In order that your patent attorney may give you an opinion as to the patentability of your idea and the probable costs of preparing a patent application, it is usually necessary that a preliminary search first be made on the patents previously issued by the United States Patent Office. This search usually takes three to four weeks to complete. Only a registered patent attorney or agent is qualified to render a professional opinion as to the patentability of an invention.

Will A Patent Guarantee a Profit?

A patent is a document issued by the United States granting to an inventor the right to exclude all other persons within the United States from making, using and selling his invention within the scope of the patent claims for 17 years from the date the patent issues. The patentee can manufacture, use, and sell his invention within the United States so long as he does not infringe on someone else's patent (although he can also do these things without a patent). He can sue and recover damages and an injunction against those who infringe his patent. He can also assign all or part of his patent to others or license others to manufacture, use or sell his invention in all or certain parts of the United States. These are the usual ways in which patentees may profit from their invention. A patent is a badge of the inventive ability of the inventor and may afford him a measure of personal satisfaction in addition to whatever monetary reward it may bring to him.

The commercial value of a patent to a patentee is extremely difficult to appraise. Where the inventor is "ahead of his time," the invention may not achieve commercial success for a considerable length of time. Sometimes the invention may have its most successful application in a field of use quite dissimilar from that in which the inventor first sought to market it. Sometimes, too, due to high manufacturing costs, firmly established competition, failure of the public to accept the invention, or for other reasons, the inventor is unable to realize any financial reward from his patent, no matter how ingenious and useful it may be.

The final test of commercial value lies in the market place. Until a patent issues to the inventor, however, or at least until a patent application has been filed with the Patent Office, an inventor who reveals his invention to a prospective purchaser does so at the risk of losing it. An expressly confidential disclosure can reduce this risk, but many manufacturers will refuse to examine an invention revealed to them in confidence for fear of subsequent claims against them in the event that they, themselves, have invented or are working on the same idea. On the other hand, if one to whom an inventor discloses his invention, even in confidence, steals it, the inventor's remedy in the courts may be extremely expensive, time-consuming, and uncertain. If the invention is believed to

have any substantial value, it should be worth protecting by the filing of a patent application at the earliest possible date. The filing of a patent application establishes with the Patent Office a date of invention for the applicant and gives him some practical protection for his claim of priority and exclusive ownership of his invention so that he can thereafter state that there is a "Patent Pending" on his invention and reveal it to others with more security. Consideration should also be given by the inventor to the desirability of filing foreign applications in those countries in which the invention may have commercial value within one year of the United States filing.

There is no objective test of the personal value of a patent. For some, the prestige of having a patented invention can result in advancement or job security. For others, personal satisfaction alone may, or may not, be worth the expense of seeking a patent. This is an individual matter which the inventor alone can decide. A patent will, however, give your invention legal protection, and hence make it a more saleable commodity, but it will not guarantee a sale nor a profit.

Cost of a Patent

First of all, there is no guarantee that the Patent Office will grant you a patent on your idea. If you apply for a patent, your patent attorney will prepare a patent application for you: a technical document containing an oath, a specification precisely and fully describing your invention in certain form, and a number of claims "staking out" your invention. In preparing and prosecuting your patent application your patent attorney is striving to obtain the broadest possible claims for your invention, so as to reduce the risk of some other inventor "inventing around" your invention, and to give you the strongest possible patent. It usually takes upwards of a month or six weeks to properly prepare the application. The Patent Office, after an extensive search of its records, allows the claims or, more frequently, objects to one or more of them as claiming too much. Your patent attorney may then respond by amendment of the application and by argument. This is called prosecution of the application. This process is repeated until the Patent Office decides to take final action, at which time it may either refuse to issue a patent at all or may issue a grant with only those claims which it has decided to allow. Your patent attorney may, if you elect to do so, appeal any rejection first to the Board of Appeals of the Patent Office and then to either the Court of Customs and Patent Appeals or to the United States District Court.

There is an additional proceeding known as an interference in which a patent application can become involved in the Patent Office. This proceeding is held to determine which of two or more applicants for patent, or an applicant and a patentee whose patent has been issued less than one year, is entitled to patent certain claims. While the prosecution of a patent application may take from six months to several years, if an application becomes involved in an interference proceeding the prosecution period may necessarily be extended an additional year or more.

It is thus impossible to foretell how much, in all, it will cost to seek a patent on a particular idea. However, your patent attorney can usually give you an estimate, in advance, of the cost of preparing and filing a patent application on your invention. Also, after the position of the Patent Office on your case is revealed by the first "Office Action," if prosecution is needed he will be able to give an estimate of the cost of preparing and filing a response thereto. The cost of further responses to Office Actions can be similarly estimated by him, in advance, after each Office Action is received. These services, and the charges therefor, are usually spread over several years. Further, you are at liberty to abandon your application at any time, if you should wish to do so.

The Patent Office minimum filing fee for filing a patent application is $65.00, but, depending upon the number and type of claims, can be $100.00 or more. If an assignment is to be recorded at the time of filing the application, the Patent Office requires an additional $20.00 recording fee for this purpose. There is in adition a final fee required by the Patent Office when a patent is issued. This charge varies with the

nature of the case, but usually approximates $124.00 to $135.00. Drawings required to accompany the application must be made by an experienced patent draftsman and cost from $40.00 to $45.00 per sheet. The Patent Office has special requirements which drawings must meet or be rejected and with which only an experienced patent draftsman is familiar. The number of sheets of drawings required will be determined by your patent attorney and depends upon the complexity of the invention and the particular views thereof necessary to supplement the specification.

The fee of the patent attorney for preparing the application depends upon the amount of time which must be spent in preparing the specification and claims and conferring with the patent draftsman plus, if not billed separately, time spent in conference with the inventor relative to the application. Separate statements are customarily rendered for consulations when no application is filed, and for consultations concerning matters not germane to the filing of a United States application.

It might be said that an inventor should be prepared to expend a total of at least $650.00 to $800.00 to file and prosecute through to final Office Action a United States patent application covering a simple mechanical invention, and from $800.00 to $900.00 on a moderately complex mechanical invention or a simple chemical or electrical invention. The cost of seeking a patent in more complex cases increases proportionately. These estimates are in addition to the cost of the usual preliminary patentability search and opinion, which is usually from $100.00 to $200.00, depending upon a number of factors. Of course, if the patent application becomes involved in an interference proceeding or if an appeal is taken, considerably more expense may be involved. All of these quoted figures can be expected to change from time to time, in step with changes in the required government fees and the fees for other kinds of professional services. The expense of filing foreign patent applications depends upon the country and in many cases must include the cost of translations.

Before investing in a patent application and its probable subsequent prosecution, an inventor or his financial backer is almost invariably well advised to obtain the opinion of his patent attorney as to the patentability of the invention, based upon a preliminary search of the Patent Office records made by an experienced patent searcher selected by the patent attorney.

If the inventor wishes to assign an interest in the invention to another person – as, for example, to a financial backer in return for financial assistance in preparing and prosecuting the patent application – such an assignment may be made at the time the patent application is filed, without the necessity of waiting for a patent to issue.

How to Apply for a Patent

Step 1. Reduce your idea to written form, describing it completely in writing and also preparing a simple sketch or sketches to illustrate it.

Step 2. Show and explain your invention to two people whom you trust and who are technically capable of fully understanding the structure and operation of your invention. Have them sign and date a statement to this effect. Keep this.

Step 3. Show your sketches, written description, and any model you may have (though a model is not essential) to a registered patent attorney or agent. This can often be done initially be mail, but it is usually desirable for the proper protection of your invention that he be able to discuss the invention with you directly, in person, before preparing the application. Complete communication relative to the invention is essential to one seeking the broadest possible patent protection thereof. For this reason it is usually best to consult a registered patent attorney or agent in your state in preference to one with whom you can communicate only by mail.

Step 4. If your patent attorney or agent recommends a preliminary patentability search, advance the expense thereof, allow him to obtain such a search from a patent searcher selected by him, and request him to render his opinion thereon.

Only a patent attorney or agent registered by the United States Patent Office is qualified or licensed to give you a professional

opinion as to the patentability of your invention, and registered patent attorneys and agents cannot ethically, and do not, advertise. Registered patent attorneys and agents are subject to the Rules of the United States Patent Office and must conform to the standards of ethical and professional conduct generally applicable to attorneys before the courts of the United States. Further, registered patent attorneys must conform to the Canons of Ethics of their respective Bar Associations.

Step 5. On the basis of examination of the prior patents revealed by the search and the professional opinion of your patent attorney or agent as to the patentability of your invention, you will then be in a position to decide whether or not you wish to file a patent application. If so, your patent attorney or agent will be able to quote you the cost of preparing and filing the drawings, specification, claims, petition and oath which constitute your application for United States Letters Patent on your invention.

20 dB BEAMS

In times past in order to make an extended expanded beam with both vertical and horizontal spacing greater than a half wave, I have gone to great trouble and expended lots of time on impedance matching leads from antenna elements to a common fifty ohm point, like with the 32 elements on two meters in the following paragraph.

Two 50 ohm leads from two 2-element yagis brought together makes a 25 ohm point, and then a coaxial quarter wave transformer is needed to bring it back up to fifty ohms again. When these two yagis were matched and phased together, another four elements had to be matched, and then go through the whole affair again. I did this eight times, plus a lot more like 4 and 4 (four times!), then 8 and 8 and then 16 and 16, and finally got a beautiful 32 element job with exciting gain, but *heavy*!

There were so darn many quarter wave transformers, pieces of RG8/U, connectors, etc., that I couldn't even haul my regular mast up with this heavyweight on top. For about one day and night I did get it up on a "jury-rig" out by the barn and started operating and working areas I never knew about before, on strictly ground wave without an opening. The second day a high wind started the mast swaying, and with the weight of all those matching sections and cables it was too much.

Another Wrong Path

You can profit by my mistakes and save *your* time. In any Read and Do program it is easy to make a false start with an idea that looks fine from a distance but soon bogs down in "details, details."

This is what happened with the projected use of the new 300 ohm shielded antenna cable. The idea here was to wire up six small yagis with this cable, join them together at one 50 ohm point, and proceed. Here's what happened.

1. The cable proved particularly difficult to handle. It is quite stiff, and the 300 ohm wires are quite small and get cut off easily. This probably could have been overcome.

2. The problem develops. Most TV antennas are designed for 300 ohm cable, so that is no problem for the TV people, but most amateurs need 50 ohms.

3. The problem gets worse. This new cable is designed to be 300 ohms under *balanced* conditions. When *not* balanced, it no longer is 300 ohms because those two wires are close to the shield. And I certainly wasn't ready to put 432 mhz baluns on 16 small yagis (on each one!) much less on 32 of them if a second 32 element was needed for that last 3 db of gain.

4. It also looked now as though it would need a balun for each cable at the distribution box end also. That did it. Crossing off the use of that nice new shielded 300 ohm cable (anybody for 100 feet at half price?), I went to the 50 ohm unbalanced line box you see detailed later in this article,

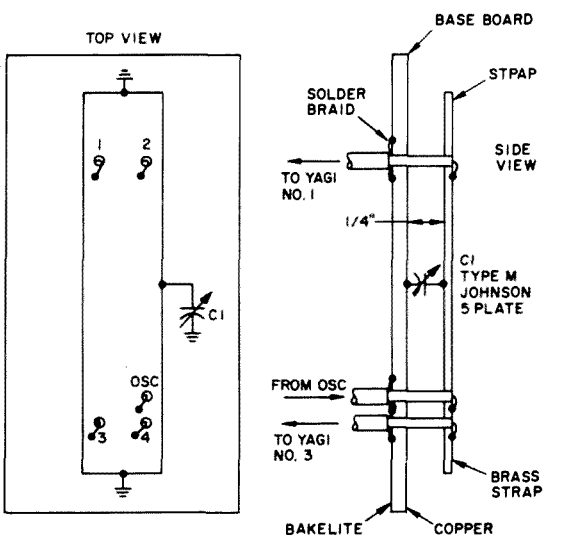

Fig. 1. Strap line rf distribution box.

which not only did a fine job, but removed the limitation of having exactly six, no more and no less, small beams to add together. Several days were lost on *that* one. Be my guest.

A Right Way To Do It

The making up of big beams of an arbitrary number of elements by adding one or more 2 element yagis at a time is accomplished by the use of a distribution box. We will start with the simple strap line type of unit and work on the basic 2, 4, and 8 elements first.

This strap line rf distribution box is shown in **Fig. 1**. With this little gem you can add on an uneven number of 2 element yagis if you want, and have them matched and phased properly. I have just finished checking this. Not that you would normally be attracted by a combination of 3, 5, or 7 small yagis, but there can be times when it might be convenient. This can come about on six or ten meters when you have a two-over-two and want to add another two, as in **Fig. 2**.

Overall Beam Size

As always in vhf beam work, mechanical considerations creep in, especially in a mid-winter blizzard! "If the beam stayed up over the winter, it was too small," is the old-time vhf man's slogan.

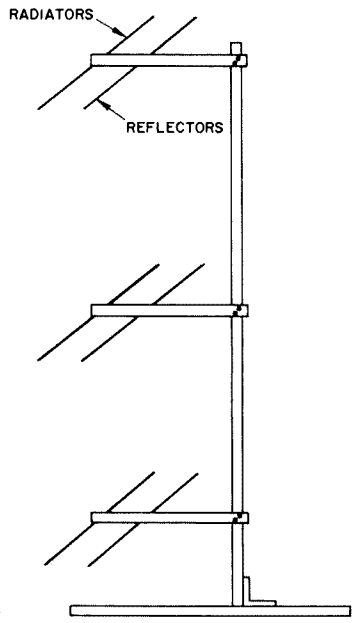

Fig. 2. 3 yagi beam.

Instead of using two-element yagis, you can increase your total power by using more than two elements per yagi. Your inter-element yagi spacing will change then, so watch that item. Some examples will be shown later. I just checked again yesterday for maximum-gain interspacing on 432 with the "standard" 2 element yagis described herein. Maximum gain side spacing radiator tip to tip is 10 inches. Vertical spacing is 18½", CC (center to center of elements).

This outlines the useful capture area and shows the fallacy of the half wave type of spacing, if you want to get the maximum gain from all that aluminum you bought, put together, and are trying to keep way up there.

Details of the "Standard" Two-Element Yagi to Get You Started

I have had good luck with aluminum clothesline material, especially for indoor

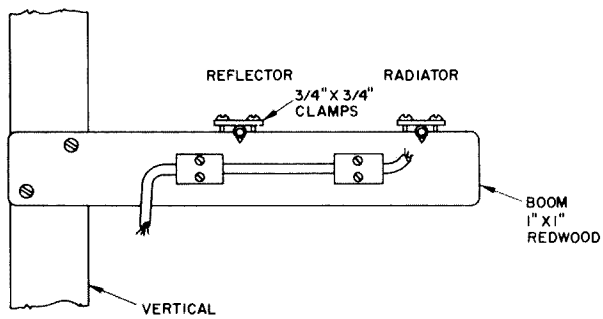

Fig. 3a. Side view, basic 2 element detail.

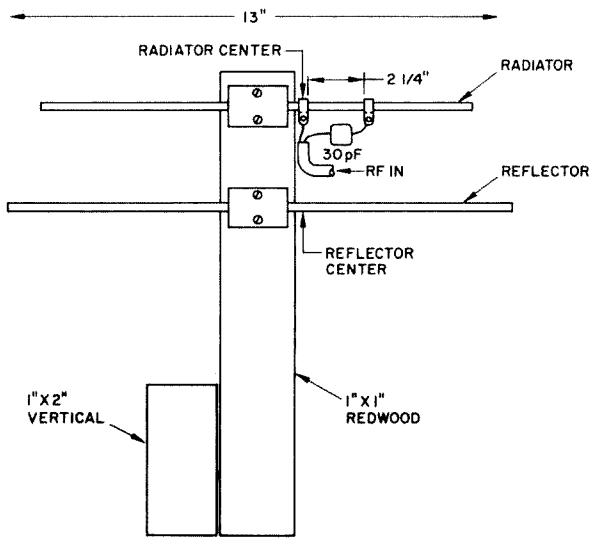

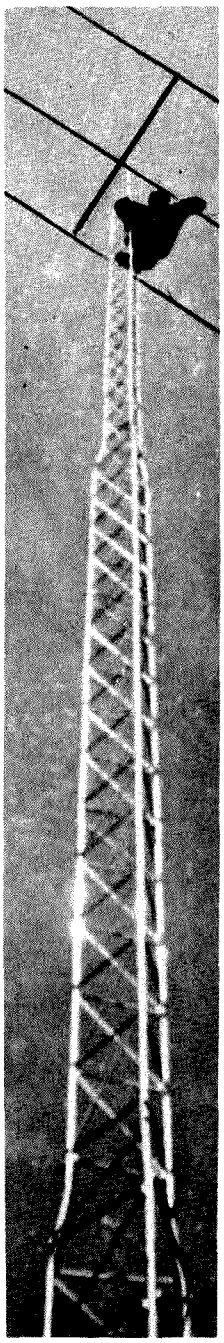

Fig. 3b. Top view, basic 2 element yagi, 432 mhz.

The "STANDARD"

72' ALUMINUM Tower FOR DX'ing

Strong, Light, No Upkeep

Self-Supporting

Easy to Assemble & Erect

All towers mounted on hinged bases

Complete Telescoping and Fold-Over Series available

*so light you can put it up all by yourself! No climbing, no jin poles, no heart attacks.

And now, with motorized options, you can crank it up or down, or fold it over, from the operating position in the house.

See your local distributor, or write for 12 page brochure giving dozens of combinations of height, weight and wind load.

HEIGHTS MANUFACTURING CO.

NOW In New Larger Facilities
In Almont Heights Industrial Park
Almont, Michigan 48003

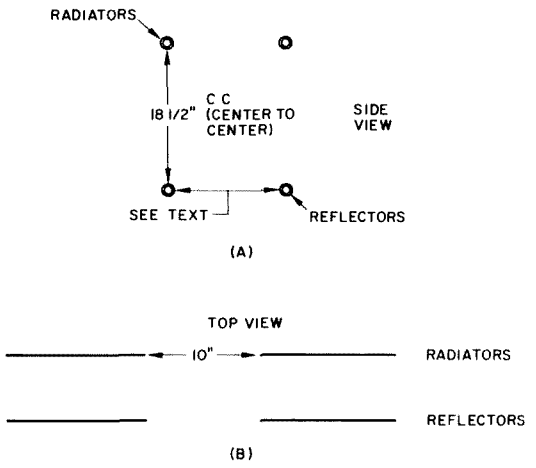

Fig. 4a. Element spacings, basic 2 element yagi.

and mobile work. If you accidently snag it on something, no harm done, just straighten it out and keep calling! It also can be found in almost every hardware store.

Fig. 3a shows some details and the use of the 1 by 1 redwood, also handy in most lumber company stocks.

You can make up lots of linen-base or fiberglass-base bakelite ¾" x ¾" cable and element holders, if you're shooting for the big beam. Remember, as far as booms are concerned, you have a choice between a large number of 2 element yagis or a smaller number of 5 element ones. I hope to find a good balance for you on this matter before I'm through.

Fig. 3b is the top view of the same basic two element job. All this work is done on 432 mhz, which can be translated to other bands by scaling up or down. However, my advice is not to trust this scaling implicity. Check it out with a small antenna range yourself. I even do this on twenty meters, and find that I can light a bulb in an aluminum dipole *five hundred feet* in front of a good 20 meter 3 element beam (the kind I used to make an sell at UHF Resonator Co., Rye, NY). I'll admit there was a good kw behind that beam at the time.

The basic 2 element described is inexpensive, but not "cheap." By the time you're all done and get that still-far-ahead 20 db gain, there will be lots of time and work spent by you.

The joint between the cable, center, C1 and its mechanical support can be improved for outside work. I have snarled this item on

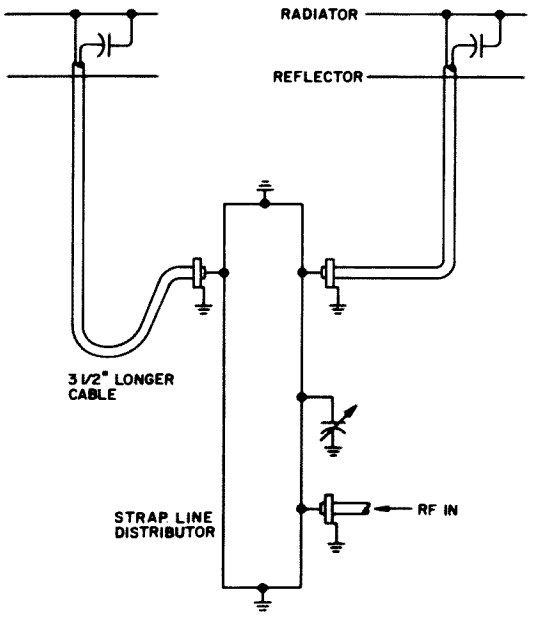

Fig. 5. Unequal cable length set up.

branches and been off the air on top of a mountain more than once! One of those little plastic boxes will do the trick for an enclosure.

The 3 DB Gain of the Second Yagi

Just finished the second one and hooked it up using the half wave distribution box (rf that is) shown in **Fig. 1**. Wow, the old meter sure climbed! Haven't checked yet for sure by the distance method, but it looks like at least 3 db, providing the diode is in a portion of its curve which is reasonably linear.

Figs. 4a and **4b** show the maximum gain spacings found, as mentioned before.

Effect of Unequal Cable Length Feeding the Small Yagis

Using the test setup shown in **Fig.5**, a 3½" cable was added to cable no. 2 to check the effect on the phasing using unequal cable lengths. It worked out exactly as it is supposed to, causing the placement of yagi no. 2 to move forward several inches for maximum gain. The added cable length causes a delay, which is compensated by putting yagi no. 2 nearer the receiver. This points up the desirability of possibly slotting the boom bolt holes to allow a final phase tune-up. So far I do not intend to do this, as I am counting on reasonably equal cable lengths to put the individual yagis in phase, but it is interesting to make it check and be sure of the effect. And then, you might just need it.

The "Parasitic" Colinear Effect

While tuning up a four element job as in **Fig. 5** and comparing gains with and without yagi no. 1 plugged in, I found that the *presence alone* of yagi no. 1, without being attached to anything, caused an increase from 10 to 13 on the meter dial, while plugging it in again jumped the meter to 15 or 16, where it should be for the full four element system. Unplugging it and removing it from the vicinity of the test stand caused the meter to register ten, which it should be for the test set-up involved when using only one yagi. So, for a gain check, remove the whole yagi, not just the plug!

This is the first time I have observed parasitic effects from colinear type elements out on the side. Might be some possibilities there.

"Insertion Loss" of the RF Distribution Box.

This business of insertion loss, a favorite term of precision engineers, only becomes important for you when it is large enough to be measured with your home-brew equipment. Naturally enough, when an engineer is handed a ten or twenty page specification from a military agency, and it says "insertion loss shall not be greater than 5 db," he's got to get crackin' on account of a little item called "Source Inspection" where some Civil Service lad from the military agency involved comes to the plant trying to ship some of those contracted items and says, "What about the insertion loss?"

With the four element beam being worked on, the insertion loss of the rf

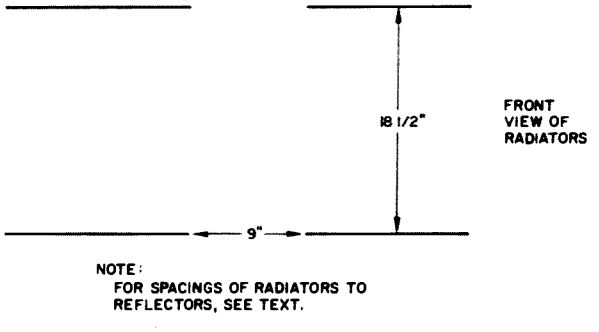

Fig. 6. 8 element spacings.

distribution box being used (**Fig. 1**) cannot be found to any great exactness because it is so small. As a matter of fact, checking the 2 element beam with and without the distribution box, at times it even shows a gain with it. There is a possibility that it is acting like a 'secondary" cavity sometimes used with certain microwave oscillators to stabilize and increase the total Q of the system and raise the output. At any rate, it is certain that good rf distribution boxes can be made for amateur uhf at low cost.

Six and Eight Elements

Just for fun I tried out the gain from the addition of only one 2 element yagi to an existing 4 element beam, and sure enough, it had lots of gain.

A word of caution for indoor, table-top antenna work. If your receiving antenna is too close, (example, only six feet) it is possible that its main cone of reception (10 db points in this case) will be too narrow to see the additional third yagi in question. In this case you will not register the real gain on the meter.

Series Coupling Capacitors and the Strap Line Resonator

The use of the strap line resonator only a quarter of an inch from the ground plane evidently has a further advantage. Looking at **Fig. 1**, series capacitors can be added between the strap line and the ends of each cable center-conductor. However, in all the

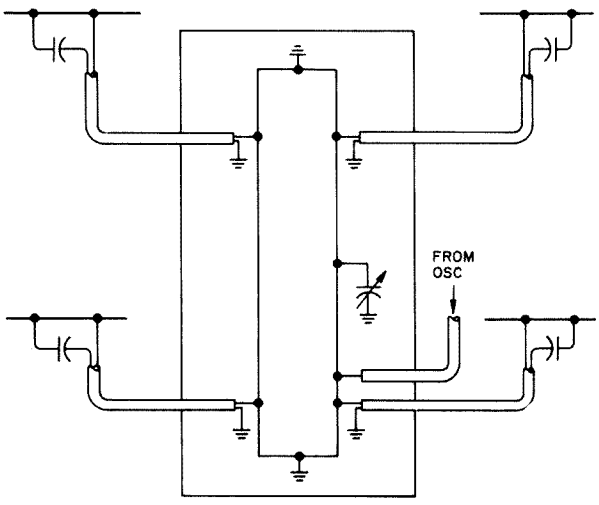

Fig. 7. Cabling diagram, 8 element.

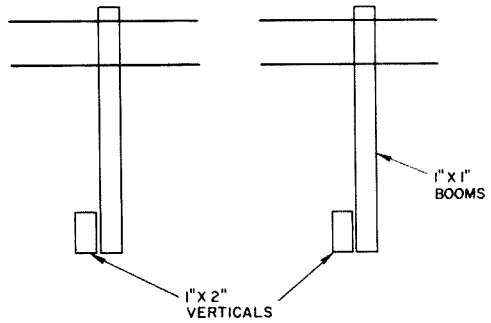

Fig. 8. Mounting detail, top view.

checks run so far, these are not needed. Theory says that when the center-conductor leaves the confines of the coaxial cable, as at the connection to the strap, inductive reactance begins to build up and requires the use of a series capacitor to cancel the inductance. Evidently the distance of ¼ inch is too small to notice at 432 mhz. As you can see in **Figs. 1** and **7** the four 50 ohm individual yagi cables are soldered directly to the strap.

Basic 8 Element Beam

Fig. 6 shows the basic 8 element beam with the final spacings of the elements and yagis. D, the spacing between radiators and reflectors, is a little controversial at present. D1 equals 2¼ inches, D2 equals 2½, and D3 and D4 equal 3 inches. This is probably due to the Gamma match capacitors, in which case one percenters may be called for. Will see what the answer is with the "Big Beam." Maybe a final tune-up point of this kind will give you that last db you're looking for.

Fig. 7 is the schematic of the 8 element, and **Fig. 8** shows boom mounting detail.

The gain of this basic 8 element beam looks very good. In the second part of this "20 DB Beam" article careful gain measurements using the distance method will be given.

The dipole; 2 element; 8 element; a 14 element yagi tuned up for maximum gain; and the 16 and 32 element beams being designed at present will be measured. Several other combinations may be tried as well, such as four 5 element yagis, four 10 element yagis, etc. *Another* 32 element may be added to the first for that last needed additional 3 db. This article may run into *three* parts, so just keep reading!

IDENTIFYING AND CONVERTING G.E. PROGRESS LINE EQUIPMENT

In the surplus commercial FM equipment market, the General Electric Progress Line equipment has often been overlooked in favor of the somewhat more popular, and possibly more available Motorola gear. The lack of good conversion information basic enough for the FM newcomer, such as has been available on the Motorola gear, has undoubtedly contributed to the lack of interest in GE equipment. I hope to provide some basic information to the ham who has or may acquire a 150 MHz Progress Line unit and would like to use it on 2 meters.

The Progress line has gone through the usual adaptations and improvements right up to the present fully transistorized models. With the exception of the transistorized versions, and some later MTS combinations, they all contain similar and interchangeable transmitter and receiver strips with all the standard features incorporated that the average ham would require. Because it is more likely that you will come upon one of the earlier Progress Line units we will direct our discussion toward them.

Equipment Identification

As a means of describing the complete unit GE employs a combination nomenclature which tells us three things; the type of housing or application, the type of power supply and its voltage, and finally, the series designation. Table 1 will explain what each designation means. While the information given may not be an exact interpretation as might come from the factory, it is adequate

Table 1
Station Combination Identification

FIRST LETTER - Cabinet Designation
- M Trunk mount
- F Front mount
- T Table top
- W Trunk mount mobile telephone application
- WT Table top mobile telephone application

SECOND LETTER - Power Supply Designation
- A 6 volt vibrator
- E 12 volt vibrator
- A/E Dual vibrator type
- T 12 volt transistor
- U 24 volt
- O 117 VAC continuous duty
- I 117 VAC intermittent duty

NUMBERS - Station Combination Series
- 33 20–25W
- 36 40–50W
- 37 100W
- 38 250W

Note: Other designations may be found from time to time, but those included here are the most prevalent. This is not intended to be an all-inclusive list.

Example:

M A/E - 36 X X
- M — Cabinet designation
- A/E — Power Supply
- 36 — Series combination
- X — Receiver bandwidth (W or N)
- X — Control designation

for our purposes and covers most station combinations in the 144 to 174 MHz band. One or two letters may follow the combinations series number to indicate receiver bandwidth and the type of control. Where the station is locally controlled, no designation is used.

Unlike the Motorola designations, the GE combination nomenclatures do not tell exactly what kind of transmitter and receiver strips are employed in a particular unit. In most cases the strips are interchangeable, as mentioned above, and you may actually find most anything inside the case. The only way to be sure is to look. Type numbers are found on the top of the chassis along the rear edge and will look something like: *4ET20A1 Rev. B.* A quick look at Table 2 will tell you just what each strip is. In the example you will note that the type number is followed by an additional set of letters indicating the particular revision of the basic strip. GE, like all the other manufacturers, have a penchant for changing a resistor value somewhere along the line or possibly adding a capacitor to improve the performance. Don't worry too much about this because the strips are essentially the same regardless of the revisions.

It is possible that you may come across a unit that was used originally as a mobile telephone. These should not be confused with the later mobile telephone versions which were called *"MTS Mobiles."* The earlier Progress Line units which were used for mobile telephone service are generally distinctive by their somewhat longer cases, usually 20 in., required by the special accessory deck needed to make it operate as a telephone. These units will have a designation like *WTA-33-W* or *WI-33* and are basically MA/E-33 units which were manufactured to Western Electric specifications. All the standard functions of a straight two-way radio are incorporated in these units and appear at the 21 pin control cable jack.

Inside the unit the strips are connected by a wiring harness that originates in the power supply chassis and terminates in several color-coded plug-ended branches and the 21 pin control cable jack. In early mobile telephone combinations the VS1 Selector panel can be removed without affecting the normal functions. If the multifrequency deck is missing, single channel, and possibly two channel, operation can be accomplished by plugging the crystals into the appropriate sockets on the transmitter and receiver strips. Just let the two plugs, the black and the blue ones, which connected the Selector panel and the multifrequency deck hang loose, as they will not hinder the operation. Someday you may acquire a multifrequency deck and all you will have to do is plug it in and do a bit of minor retuning.

All tube type 150 MHz Progress Line combinations employ 4ER25 model receiver strips with the suffix A through F. If yours is an E or F, look for a lot more work, as

Table 2

Transmitters

Frequency Range	144–152 MHz		152–174 MHz	
Nominal Power	1 Freq.	2 Freq.	1 Freq.	2 Freq.
20–25W	4ET20A1	4ET20A11	4ET20A2	4ET20A12
40–50W	4ET21A1	4ET21A11	4ET21A2	4ET21A12

All transmitters are continuously adjustable for 0–15 kHz deviation for narrow or wide band operation.

Receivers

Frequency Range	144–152 MHz		152–174 MHz	
	1 Freq.	2 Freq.	1 Freq.	2 Freq.
Narrow Band	4ER25A1	4ER25A11	4ER25A2	4ER25A12
Wide Band	4ER25B1	4ER25B11	4ER25B2	4ER25B12
Narrow Band[1]	4ER25C1	4ER25C11	4ER25C2	4ER25C12
Wide Band[1,2]	4ER25D1	4ER25D11	4ER25D2	4ER25D12

[1] These receivers are later versions and employ fewer tuned stages to attain the same rated performance.

[2] Models 4ER25D03 and 13 are 130–150.8 versions.

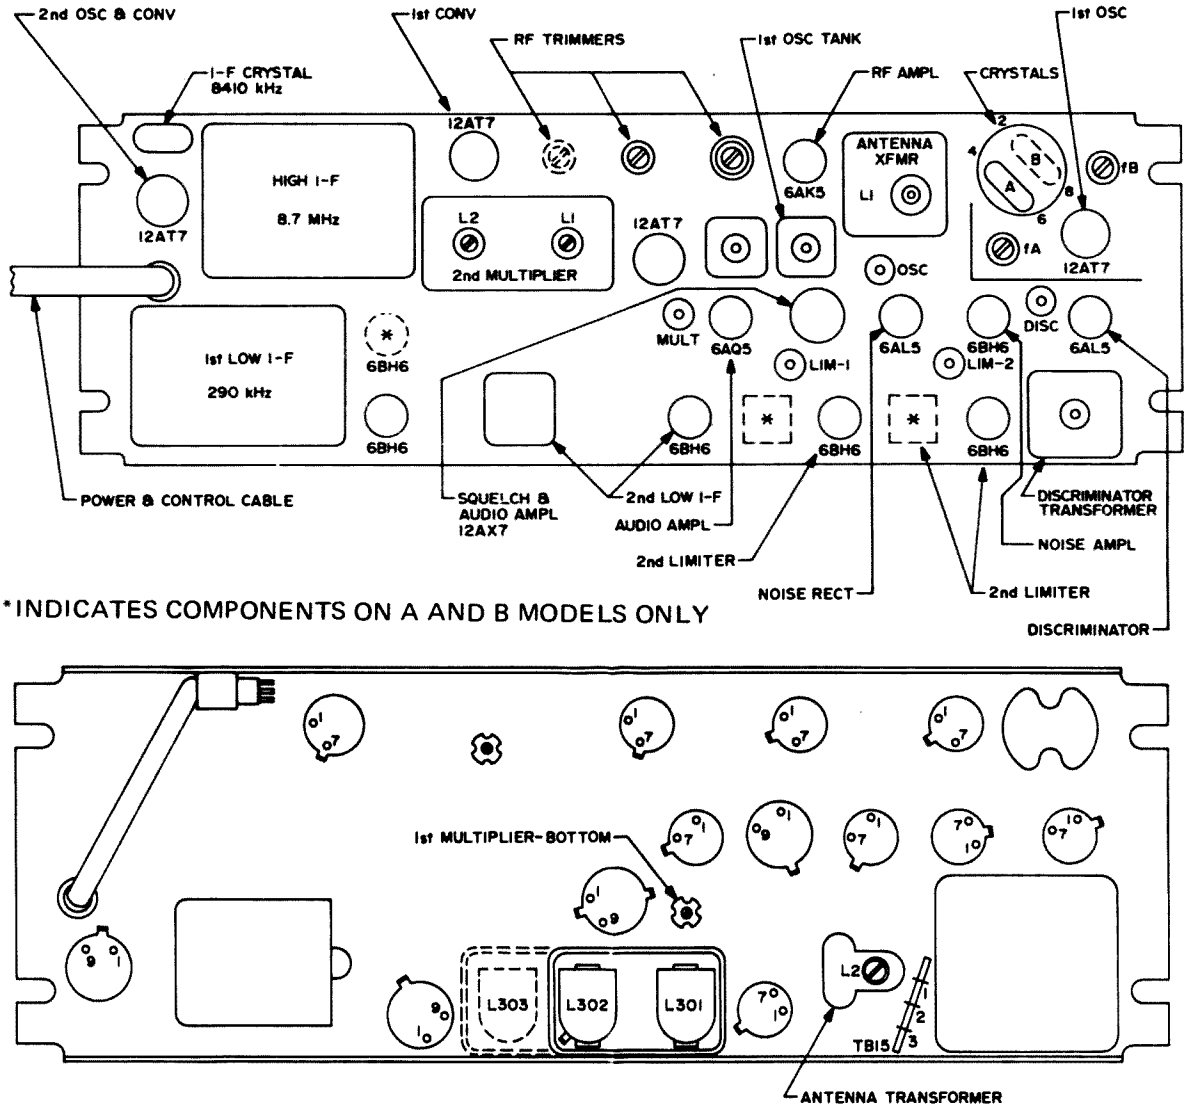

Fig. 1. Location of components on receiver chassis.

these are used in later duplex combinations and will require external modification to provide squelch and volume controls. You can also expect to rework or replace the power supply as it will be delivering power to both the transmitter and receiver at the same time. You will also find that your Progress Line unit will have either a 4ET20 or 4ET21 transmitter strip in it, even in the duplex combinations, although the duplex versions utilize a duplexer which will have to be replaced by an antenna relay or a TR switch. A recent article (*QST*, June 1971) may help in converting from duplex to simplex operation in the later MTS Progress Line units.

Now let's get down to the business of the actual conversion. More than likely you will find that your unit will be for the 152 to 154 MHz portion of the band. A few simple steps will bring the unit into the FM portion of the 2 meter band.

Crystals

For best results and ease of ordering, commercial standard crystals are the easiest. All you have to do is specify the type number of the strip you are ordering the crystals for, the crystal frequency, the channel frequency and whether you intend to use it in an oven. Check your favorite crystal catalog for the specific information they require.

The transmitters have a multiplication factor of 24, so just divide the desired operating frequency by 24 to determine the crystal frequency. The first oscillator crystal frequency for the receiver can be determined by subtracting 8.700 MHz from the channel frequency and dividing the results by 12. If

you are lucky the receiver will have the i-f crystal in it; if not, order one for 8.410 MHz. While you are waiting for your crystals to come in the mail, you can start on the next steps.

Receiver Conversion

To obtain at least rated sensitivity[1] it is necessary to pad several places in the receiver. The trimmers used in these receivers can be turned a full 360° and will give the impression of being fully peaked when actually you are only passing through the maximum capacitance point of the trimmer. You can approach the padding in one of two ways: install a new capacitor of the correct value at each point to be padded or get a handful of 4 pF capacitors and parallel the existing capacitors with them. The purists among us will undoubtedly use the first way, the rest of us the second way. Either way use good quality 500 wvdc tubular ceramics with −80° temperature coefficient.

In the A and B models there are seven places to be padded and six places in the C and D models. Start by removing the strip from the unit to facilitate handling as you will be turning the chassis over several times. Refer to Fig. 1 to locate the coils that are to be padded. Be sure to check Table 2 to determine if padding is necessary in the receiver you have.

A quick inspection of the antenna transformer and the rf trimmer cans will tell you what is required to remove them so the coils can be reached. L1 will come off with the can and can be removed by taking out the three screws on the side of the can near the antenna input jack. Note the position of the screws in the slots so that L1 can be replaced in essentiallly the same place, although you may want to slide it up or down for best results as indicated by the LIM-1 meter reading when you tune up.

The can which contains the second multiplier coils is far more difficult to remove and care must be exercised to prevent damage to the components inside. When the receiver was manufactured the components were installed in the loose can and then wired. The can was positioned on the chassis and the leads fed through to the bottom side and soldered in place. Reversing this procedure, while difficult, is probably better than trying to remove the can without unsoldering, although I have done it in this way. Remember to tag the leads. The following list indicates the required padding capacitor values.

	Coil	Existing Capacitor Value	Change To
Antenna	L1	10 pF (C2)	14 pF
Transformer	L2	6 pF (C4)	10 pF
Rf Trimmers	L301	3 pF (C309)	7 pF
(see note	L302	9 pF (C306)	13 pF
below)	L303	None	4 pF
Multi-2	L1	7 pF (C2)	11 pF
Transformer	L2	10 pF (C3)	14 pF

Note: In the C and D models L303 has been eliminated. However, use the values given for L303 for L302 in these receivers.

If the receiver strip is equipped with a trimmer below the opening marked fB, the receiver is capable of two frequency operation. However, upon inspection you may find that pin 3 of the first oscillator tube socket had been permanently soldered to ground, which makes channel A operative continuously. Assuming you want two frequency operation, unsolder pin 3 from ground and add a short length of hookup wire between pin 3 and lug 1 of TB15 (lug 1 is the one with the green braid covered wire leading directly to it from the cable). TB15 is directly below the antenna transformer (see Fig. 1). If it is not already in place, add a wire similarly between pin 8 and lug 2 of TB15. Leave both of the 0.02 uF disk capacitors in place on TB15. Also solder a short piece of hookup wire between pins 1 and 6 to complete the plate circuit of the section of the oscillator. You should now be able to select channel A or B from the channel selector switch on the control head.

If the control head is not equipped with a channel selector switch one can be added easily. Install an spdt toggle switch in a convenient location on the control head and ground the common terminal. If the control cable leads are marked, connect wire #12 to one side of the switch for channel A and wire #13 to the opposite side for channel B. If you are adapting a control cable that is not numbered, simply ring out for conti-

[1] Rated sensitivity: 0.5 μV (20 dB quieting method).

nuity between pins 4 (channel A) and 5 (channel B) of the 21 pin control cable plug and connect the loose ends to the control switch as described above.

All 4ER25 type receivers can be converted to two frequency operation by adding a 39K, ½W, 10% resistor and a 3 to 12 pF ceramic trimmer as shown in Fig. 3 and making the changes described above for frequency selection.

Tuning the Receiver

With the appropriate crystals in their sockets, apply power to the receiver and let it warm up. Using a 20K ohms/volt vom with a 2½–3V dc scale, ground the positive lead to the unit in the GND test jack on the power supply chassis. Insert the other lead into the OSC test jack. Tune the first oscillator tank to maximum and then back off on the gentle slope side until you have a reading of about 1.35V. If you are using commercial standard crystals cut specifically for the unit, you will generally get the greatest output from them at or very near the correct frequency. Adjust the oscillator trimmer (fA or fB) for maximum meter reading and then readjust the tank coil until you again have about a 1.35V meter reading. In multifrequency applications the oscillator must be tuned on the highest channel frequency.

Next, move the test lead to the MULT jack and tune the first multiplier coil, both top and bottom alternately, for maximum meter reading.

With the meter probe in the DISC jack, connect a signal generator to the antenna input jack and zero the generator to the discriminator. Move the meter probe to the LIM-1 jack and reduce the generator output to the lowest value that gives an indication on the meter. It is possible that you may not get a reading at this time. If this is the case, move the meter probe to the LIM-2 jack and with maximum signal generator output, adjust the antenna transformer top and bottom, the two trimmers of the MULT1-2 transformer and the two or three rf trimmers for maximum indication. Return the meter lead to the LIM-1 jack and repeat each of these steps. As the meter readings increase due to tuning, reduce the generator output to the minimum needed to give an indication. Too much signal will saturate the limiters and give a poor indication. Occasionally move the meter probe back to the DISC jack and zero the generator as necessary.

Finally, with an antenna connected to the receiver, listen for an on-the-air signal and adjust the OSC-1 trimmer so that you get a zero discriminator reading. Remember that the guy you hear may not be exactly on frequency, but if someone else can hear him

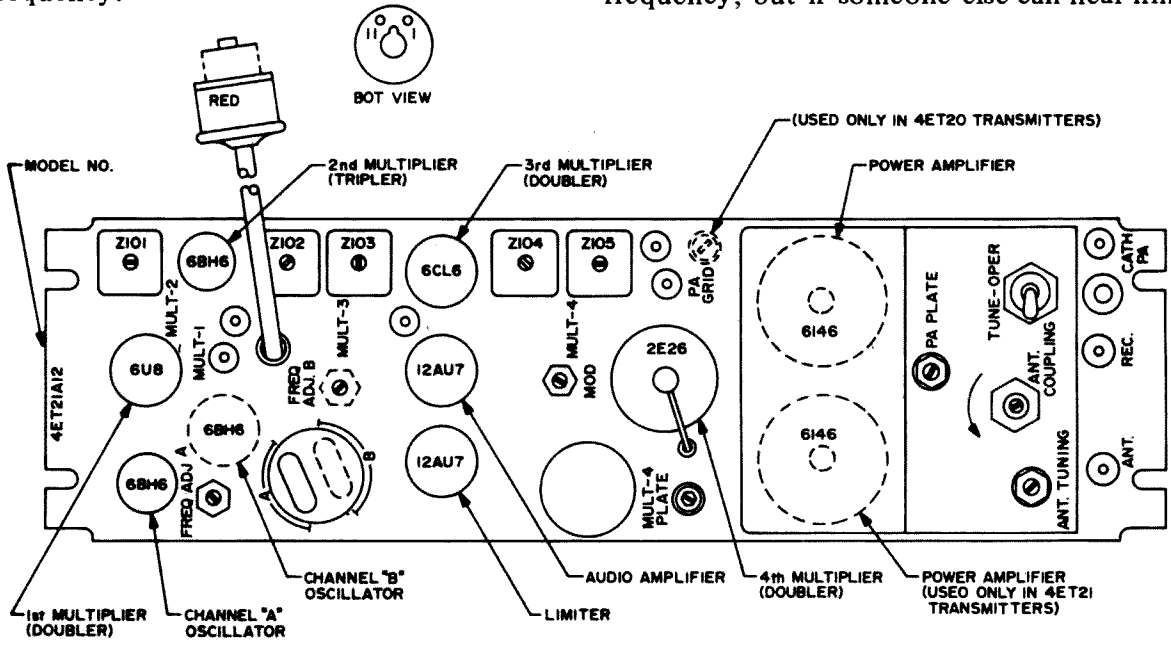

Fig. 2A. Location of components on transmitter chassis.

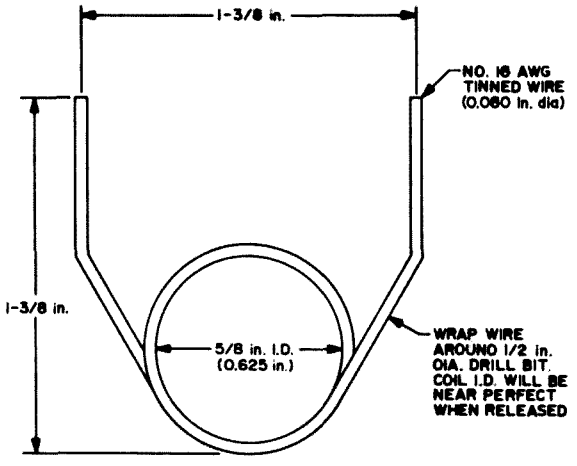

Fig. 2B. Power amplifier plate coil replacement.

it's a good bet that he is at least close. You can always touch it up a bit later on when you find someone known to be on frequency or when you acquire that secondary standard.

It is worthwhile to go back over all of the above adjustments while listening to a steady, clean signal that gives about 0.5 to 1.0V LIM-1 reading.

That's about all there is to getting your receiver to work reasonably well. Adjustment of the i-f, limiter and discriminator stages will usually not be necessary and should be avoided. If you must adjust these stages get a copy of the appropriate bench alignment procedure published by GE, if possible, before you attempt it. The coils in these stages are overcoupled and must be loaded with the proper load resistor to make them critically coupled and then tuned in the proper sequence for good results.

Transmitter Conversion

Only one relatively simple change is required to make the 152 to 174 MHz units work in the 2 meter band. The power amplifier plate coil (L113) must be replaced with a new coil made up as shown in Fig. 2B. The coil should be fabricated of tinned 16-gage wire (0.08 in. diameter) wound 1 1/3 turns at five turns per inch, to an internal coil diameter of 0.625 in. (5/8 in.).

Remove the perforated cover from the power amplifier housing, pull out the 2E26 drive tube and the PA tube so you can reach the coil to work on it. Carefully unsolder the rf choke attached to the bottom of the coil loop. To make coil removal and replacement easier, remove the nut holding the PA plate tuning capacitor and the two screws on either side of it and slip the coil, capacitor and the steatite posts out of the housing. Unsolder the large recetangular plate coil and remove it from the clips. It may be possible to make your new coil out of the old one,although I have never tried it. Insert the ends of the coil into the clips to the approximate position and solder one side. Reinstall the entire assembly into the housing. Adjust the coil up or down until it is even with the load coil by heating first one side, then the other, and making slight adjustments in the coil height until the correct position is reached.

With the loading coil turned fully counterclockwise, adjust the new plate coil so there is 1/16 in. between it and the loading coil. Solder the free end of the rf choke to the center bottom of the front loop of the new coil, i.e. as you look into the open end of the PA housing. Be sure that in soldering in the rf choke you have not shorted the plate coil. Recheck the coil turn spacing and the distance between the two coils, and if all is well replace the tubes, plate caps and the housing cover and proceed to tuning up the transmitter.

Tuning the Transmitter

Transmitter tuning is basically a matter of peaking and dipping the various stages and should present no formidable problems. With the proper crystal in its socket, apply power and let the transmitter warm up. Flip the TUNE-OPERATE switch to the tune position and turn the ANT COUPLING countrol fully clockwise (uncoupled). The transmitter must be in its case or resting on a metal plate while it is being tuned or it will be detuned when it is returned to the case. Connect the unit to a dummy load for the initial tuneup procedures.

Plug the positive meter lead into the GND jack on the power supply and the negative lead into the MULT-1 jack. The oscillator and modulator stages are working properly if the reading is 1.5V or more. Move the meter lead to the MULT-2 jack and tune Z101 for maximum meter reading. *Do not key the transmitter for longer than 30 seconds at a*

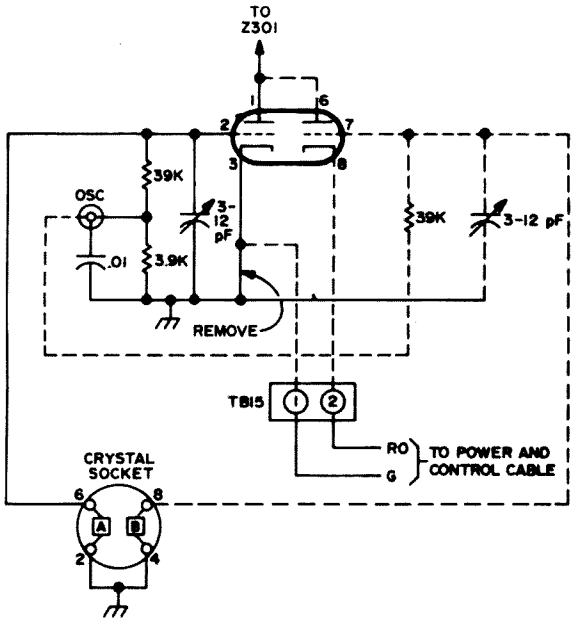

Fig. 3. First oscillator circuit of receiver. Add dotted wiring for two frequency operation.

time until after the MULT-4 plate has been tuned.

With the meter lead in the MULT-3 jack, alternately peak Z102 and Z103 for maximum meter reading. The best way to tune this stage is to turn the adjusting screws in about ¼ turn each alternately, until the maximum reading is reached. If a peak cannot be obtained, connect the meter to the screen (pin 6), using the 300V scale, of the 6BH6 second multiplier and tune Z102 for a slight dip in screen voltage. It is possible to tune Z102 and Z103 to the wrong harmonic of the crystal frequency. If this is suspected, turn both of the adjusting screws all the way out (counterclockwise) and retune to the first peak in the manner noted above.

Next, plug the meter into the MULT-4 jack and alternately tune Z104 and Z105 for maximum meter reading. If this stage is badly misaligned, pretuning can be accomplished by tuning Z104 for a slight dip with the meter lead plugged into the MULT-3 test jack.

Now move the meter lead to the PA GRID test jack and alternately tune MULT-4 PLATE and PA GRID controls for a peak (MULT-4 PLATE only in ET-21 type transmitters). A small voltage reading will be present at the start because of the fixed bias at this point.

For each of the following steps the negative meter lead must be plugged into the GND jack and the positive lead into the CATH PA jack.

Tune the PA PLATE for a dip. Dip MULT-4 PLATE and PA GRID (if it is present). Flip the TUNE-OPERATE switch to the operate position and quickly redip these controls. Alternately tune the PA PLATE and ANT TUNING controls until a lower reading cannot be obtained. When the minimum reading is reached, retune ANT TUNING for a peak. If there is no indication of a peak increase the coupling by turning the ANT COUPLING control slightly counterclockwise until a peak can be seen. Increase the ANT COUPLING until the meter reads 1.4V and again adjust the ANT TUNING for maximum indication. The ANT COUPLING should now be increased until a reading of 1.6V for ET-20 models and 1.5V for ET-21 models is obtained.

Move the negative meter lead back to the PA GRID jack and the positive lead to the GND jack and retune MULT-4 PLATE and PA GRID for maximum indication. Once this is done, and with an antenna connected, return the meter leads to the CATH PA and GND jacks as in the steps just above, and adjust the ANT TUNING control for maximum meter reading. The ANT COUPLING should be readjusted to 1.5 or 1.6V.

The transmitter should now be putting out at least its rated power of about 25W. Greater output can be obtained by increasing the ANT COUPLING or replacing the 6146 final with a 6146B in the ET-20 models. There is the danger of overloading the power supply, however, unless the unit is equipped with a high power supply (two transformers) which may be present, particularly if the unit had once been used as a mobile telephone. In this case it may be possible to obtain up to 40 or 45W from a single 6146B final. The modifications described above should result in performance at least equal to the manufacturer's ratings assuming all of the tubes are good. A gain antenna will help immensely and with a good preamp ahead of the receiver, sensitivities as low as 0.1 to 0.2 mV are possible.

PHASING MULTIBAND VERTICAL ANTENNAS

Most amateurs don't have the space for rotatable directional antennas for the 40 meter band—not to mention 80 meters—yet these are our most crowded bands under average conditions. Some sort of directional antenna is of tremendous value for stateside contacts and almost a must for DX. Many hams with limited space are using trapped multiband verticals. With a decent ground system, these are wonderful antennas, but they aggravate the QRM problem even more with their omnidirectional characteristics.

The use of two or more multiband trapped verticals and the proper phasing and switching setup provides an inoffensive (to the neighbors, I mean) and very effective method of obtaining directivity. This is essential for overcoming at least some of the QRM on receiving, and for giving that extra kick to your signal that can mean the difference between a solid QSO and none at all.

If you are presently using one trapped vertical, you already have almost half the system. I am sure every dedicated 40 meter operator will take pleasure in hearing Radio Moscow drop 20 to 30 db at the flip of a switch.

Some Theory

Since many handbooks barely mention phased verticals, a little theory is in order. For an example, let's use two identical verticals spaced one-half wave length apart (**Fig. 1**) and driven equally and in phase. The fields of the antennas are uniform in all directions in the horizontal plane and look like point sources of circular waves as viewed from above. Any point along the line W-E is a half wave length further from one vertical than the other. In other words, at any point along the W-E line, the two radiated waves are 180° out of phase and cancel. At any point along the N-S line (broadside) the

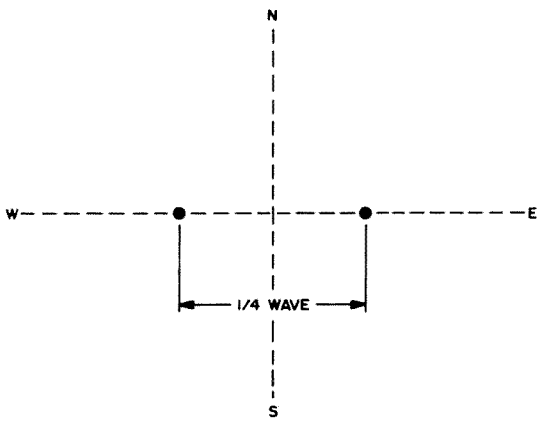

Fig. 1. Top view of 2 vertical antennas with ½ wave spacing.

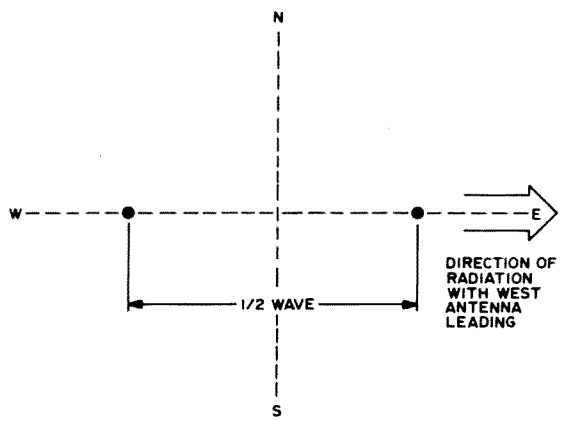

Fig. 2. Top view with ½ wave spacing.

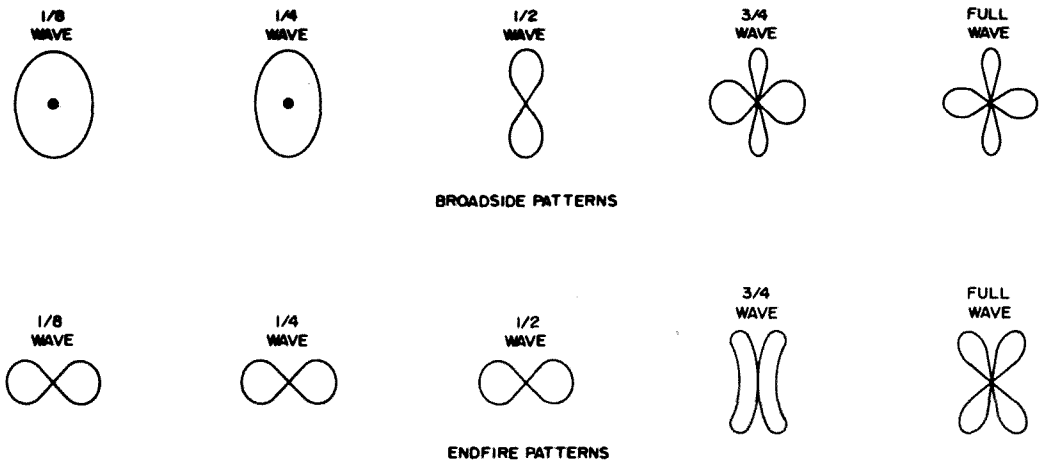

Fig. 3. Phased vertical radiation patterns for various spacings.

waves are in phase and reinforce. This then is a broadside array.

If the antennas in Fig. 1 were driven 180° out of phase, by feeding one antenna directly and inserting a 180° coax delay line in the other feeder, there would be reinforcement along the W-E line (endfire) and cancellation on the W-S line. So by using the same antennas and switching the appropriate length of coaxial cable in and out of the feedline, we have a choice of two directions, N-S or E-W.

If the verticals are spaced a quarter wave length apart (Fig. 2) and driven 90° out of phase with the west leading, the pattern will be a cardiod (heart-shaped) toward the east. Broadside gain for half-wave spacing is 3.86 db and 2.3 db for endfire with side attentuation around 20 db. A front to back radiation of up to 30 db can be achieved with quarter wave spacing for the cardiod pattern. Radiation patterns for various spacings are shown in Fig. 3.

As with any multiband system, there are some disadvantages. Definite endfire–broadside patterns are obtainable with eighth-wave, quarter-wave, and half-wave spacing. For full-wave and three-quarter-wave spacing, the patterns are not so cut and dried. A full-wave broadside pattern somewhat resembles a 4-bladed propeller, and the full-wave endfire pattern fills in the gaps between the 4 lobes (or blades). Even so, this directivity can be used to advantage by careful plotting on a great circle map or by the use of an "S" meter.

Practical Design

The first step in setting up a phased vertical system is to decide on the spacing. This will be determined by either physical limitations (how big your yard or roof top is) or by your choice of bands. For example, if you enjoy 40 meter DXing, quarter-wave spacing for 40 meters will result in very usuable eighth-wave and half-wave patterns for the 80 and 20 meter bands respectively. The antenna will be most effective on 40 because the quarter-wave spacing also yields a cardiod pattern on this band. The three-quarter and full-wave spacing result in the four lobed patterns on 15 and 10 meter bands.

The second step is deciding in which direction to beam the patterns. For instance, mounting the verticals on the N-E–S-W plane will put a 40 meter cardiod pattern towards Europe and another towards Australia and New Zealand. The broadside pattern will fall on Alaska and South or Central America. Reference to a great circle chart centered on your QTH will resolve this problem.

Step three is tougher: the physical mounting of the two radiators. As with any vertical antenna, success or failure lies in the ground system. There are too many hams who curse the vertical antenna that they

"tried back in 19 and Blah Blah" and took down the following spring because it didn't work. Almost invariably, further questioning reveals an inadequate ground system or attempts to use the antenna for consistent short range work. Having successfully used verticals at five different locations in four states, I would recommend a roof or mast mount with at least three drooping radials for each band. Multiconductor TV rotator cable can be used to avoid having your yard look like a giant spider's lair. Measure and cut each conductor to a quarter-wave for each band desired, as shown in **Fig. 4**. Tie and solder the antenna end to a lug and you've got a multiband radial. Three such radials drooping from the base of the vertical make a very effective counterpoise. A roof mount in the average location has the added advantage of allowing you to mount the radiators well clear of nearby objects, thus helping maintain identical radiation patterns. Bear in mind that the success of the phasing depends on the words "identical patterns." If you are fortunate and live in a swamp, it would, of course, be best to use buried radials.

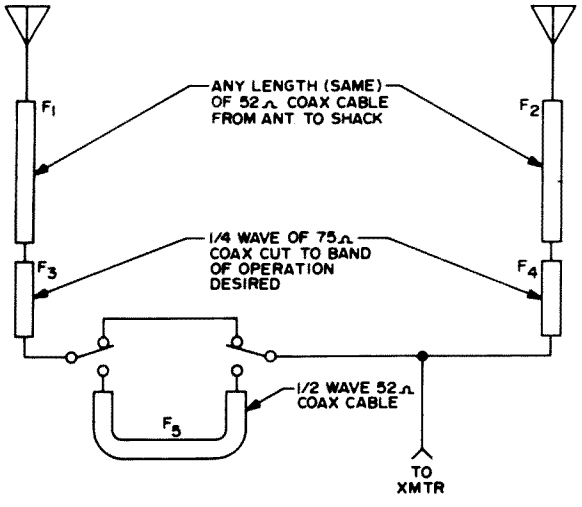

Fig. 5. Basic broadside-endfire switching.

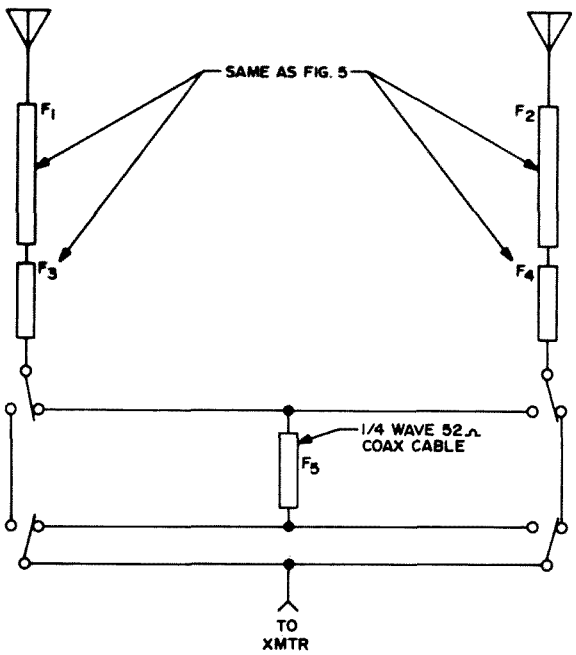
All directional and band switching can be done from inside the shack. Identical coax feeders of the same length are brought from the base of each antenna into the shack. The lengths of these lines can be ignored for the phasing line calculations because they are the same length.

Phasing Lines

Fig. 5 illustrates the basic endfire–broadside arrangement using full to one-eighth-

wave spacing. Feeders F1 and F2 are any equal length needed to bring the feeders to the switching point. F5 is shorted for broadside, and switched in the circuit for endfire. Fig. 6 shows a cardiod pattern setup for two directions. F5 in this case is one quarter-wave long, and the antennas are spaced a quarter-wave length apart. If F5 is switched out of both feed lines, the antennas are in phase and a broadside pattern results.

The phasing line lengths can be calculated from the formula: one-quarter wave x velocity factor frequency. The velocity factor for regular coax is .66, and for polyfoam it is .75. It is necessary to switch phasing lines F3, F4, and F5 for each band. This seems rather complicated at first glance, but it can be done with two switches. The switches can be mounted in a large minibox with coaxial connectors on the rear for all the phasing lines and antenna feeders. The use of coaxial switches would be the best approach although rather expensive. Excellent results can be obtained with good quality ceramic switches such as ones currently available on the surplus market. If the switch box is built using coaxial connectors for all the phasing lines, it might be wise to purchase these surplus also in order to keep costs down.



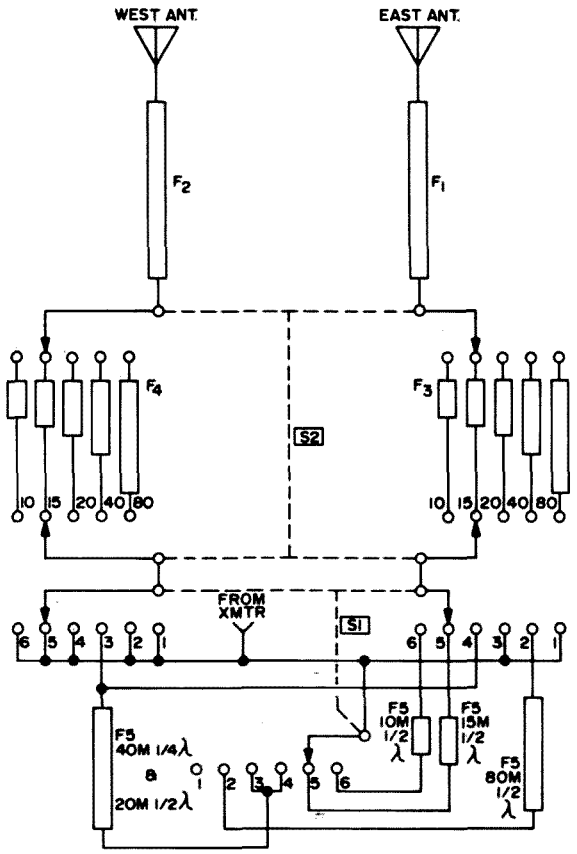


Fig. 6. Basic cardiod switching with quarter wave spacing.

4. 40M EAST CARDIOD AND 20M END-FIRE.
5. 15M END-FIRE.
6. 10M END-FIRE.

Fig. 7. Switching arrangement for 5 band trapped verticals.

Switch Box Construction

A practical example of a band switching system evolves from Fig. 5 and 6. This is shown in Fig. 7. Two switches are used: a 5 position, 4 pole and a 6 position, 5 pole. If the trapped verticals in your installation cover 40 through 10 meters, one position can be eliminated or terminated in your dummy load for tune-up purposes. Keep leads short and no problems with high SWR will be experienced.

To avoid confusion, both ends of each phasing line can be marked with adhesive tape and a ball point pen. The phasing lines can then be neatly coiled and stacked in a box (or perhaps a wastebasket) under the operating table. A lot of effort is involved in a good antenna system, and this one is no exception. I think you'll find, as I did, that the returns versus effort ratio is pretty high.

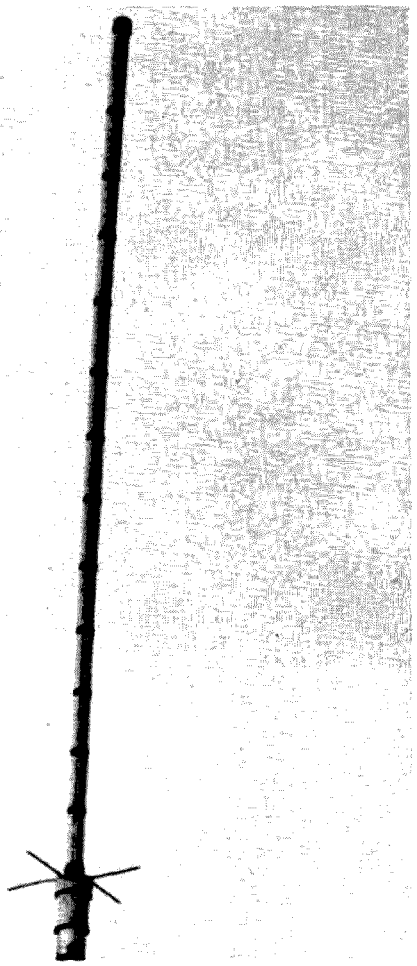
HAM TV: A Public Service

Ham radio has, since its inception, been permitted and sometimes tolerated by the federal government primarily because of its value to the nation in times of disaster. As a consequence of this, ham radio clubs have frequently allied themselves to the various Civil Defense programs around the country. Like many of these clubs, the Marshall County Amateur Radio Club of Plymouth, Indiana, has followed this route. Unfortunately (?), no calamity appeared to afford our club the opportunity to make use of our meticulous preparations. Our energies were channeled toward preparing for events whose possibility of coming about were remote.

Consequently, the club began looking for a service-type project to which the club could devote itself. Although some members put the project described here on a par with the above mentioned calamity in terms of actually reaching fruition, the club decided to give the project a try.

The motto that "amateur radio exists because of the service it renders," took on real meaning for our club. On September 6 (Labor Day), some 15,000 people viewed the annual Blueberry Parade in Plymouth, Indiana. Among these were 100 shut-in nursing home patients. The latter were provided with the televised coverage of the parade through the courtesy of the Marshall County Amateur Radio Club.

Shortly after an article on ham TV activity in this area appeared in the local newspaper I was approached by the publicity chairman for the parade. After considerable discussion with other active ham TV'ers, Wayne Zehner WA9INM and Bob Newcombe K9ZLM, who confirmed that the project was within the realm of technical capability even with our homebrew and sometimes downright crude equipment, it was decided to approach the club with the idea. After the question of legality was solved, the club decided to give it a try and preparations began in earnest.



Since the purchase of 432 MHz antennas was beyond our financial resources, an antenna construction fest was organized. These antennas were bow-tie types with a solid metal reflector constructed out of blocks of

wood and aluminum salvaged from discarded highway signs. To facilitate construction it was decided to not use gain antennas at the receiving end of the network with the exception of one nursing home which was located approximately 5 miles from the transmitting site. At this location a 16-element collinear coupled with a preamp was installed. The lack of gain at the receiving ends was offset by a 10-element vertically polarized collinear transmitting antenna (July 71 *73*) constructed by WA9INM and K9ZLM. Vertical polarization was mandatory since the nursing homes were scattered at all points of the compass.

WA9INM began converting a surplus ART-28 for an outboard on a Motorola T-44 strip. After exhausting the expletives in the English langauge, WA9INM found that the Motorola strip wouldn't develop enough drive for the theoretically half-gallon ART-28. Due to a lack of test equipment operating in the 430 MHz range, this fact was discovered too late to allow time to start over. It was decided to use an RCA CMU-15 bare-foot. The fact that it developed an adequate 20W in a test run two weeks prior to the actual parade proved this unit to be more than sufficient to insure completely snow-free pictures at all 5 receiving locations.

W9JER asking for a video check from WA9INM at the business end of the in line and off the air monitors. WA9TZP, club president, is at left next to the club TV idiot card.

Ten-element collinear transmitting antennas constructed according to description in the July issue of 73.

After the antennas were constructed, the only problem – equipment wise – was obtaining converters for each of the receiving locations. Somehow the club managed to scrape up a sufficient number of ultraverters of the type Americans used to use before the FCC required manufacturers make UHF tuners standard on all TV sets. These ultraverters were slugged to tune 432 MHz and used channel 3 for the i-f.

On the test day everything was set up as closely as possible in the same manner as it would be on festival day. The 10-element collinear transmitting antenna and transmitter was set up on top of the 60 ft Plymouth Building on Michigan Street next to the reviewing stand. The transmitting antenna was on top of a 30 ft portable mast which gave us a total of 90 ft. To achieve

WA9INM watches for parade as W9JER pans local scenery.

his height, it was necessary to run 400 ft of RG-59U video line from the TV camera at street level to the transmitter. In order to overcome the line loss the target on the camera had to be turned up to an undesirable level. Regardless of the negative effect this would have on the camera when operating continuously for at least 2 hours, the video information portion of the signal rose to almost or equal level as the sync pulses which made for considerable tearing of the picture. Dick Basham K9ILU solved this problem by procuring a video amp from our local telephone company and his employer. He also obtained five combination headset-microphone sets from them which were used for closed communications with the camera, transmitter site and camera spotters.

Realizing that the FCC might frown upon duplication of services provided by commercial concerns, it was necessary to use the audio portion of the telecast from WTCA, the local radio station. The local engineer cooperated fully by setting up the announcers' table directly across the street from our camera site. Each nursing home was then provided with an FM radio, and in effect had a description of each parade entry as it passed, because the cameraman was plugged into a portable radio and thus was able to keep the camera on the entry being described by the radio announcer.

The day of the parade itself finally arrived with – you guessed it – rain. However, since hams in general have always been amply blessed with optimism, the club assembled and began setting up the transmitter, camera and all other related paraphernalia. Just when we began to lose some of that optimism, Mother Nature cooperated and the moisture ceased. Despite being a little damp, everything worked, and the club members took up their stations; Dick Basham K9ILU and Dale Schrom K9KRT, transmitters; Bill Washburn WA9TZP (the club president) as camera spotter and public relations; Wayne Zehner WA9INM and Bob Newcombe K9ZLM as troubleshooters; Everett Easterday WB9GSI, Red Easterday WB9AHF, Carl Bovee W9DHF, Mildred Bovee K9ZLB, Clarence Shaffer WA9VRK and Fred Doss WA9VRV at the various nursing homes; and I was on the camera.

For ID purposes a test pattern containing WA9INM's call letters under whose call the televising was conducted – and who incidentally was the prime mover behind the whole project – was positioned so that it could be shot at 10 minute intervals.

Amazingly, everything proceeded as planned, with only one exception. The first time Jerry W9JER, the cameraman, tried to zoom in a well-endowed majorette, he got the full force of 100V. Somehow there was ac on the camera chassis. This coupled with wet feet made for a "shocking experience." Not wanting to interrupt the coverage, WA9INM, the chief engineer, declined to reverse the ac plug. The televising continued, but the situation eased as everything began drying out.

About midway through the parade the odor of burning insulation permeated the camera platform. The thought of a $1200 camera going up in smoke sent everyone scurrying to ascertain the source of the odor. The problem was solved by an untechnical bystander who pointed out the smoking brakes of a horse-drawn wagon. It seems that the old timers constructed their wagon brakes out of material similar to that used in today's wire insulation. At least they smelled the same.

Aside from a brief light shower, the remainder of the parade went off without a hitch and even the transmitter did not blow as expected, since a CMU-15 is not rated for continuous duty. As soon as the last parade

two or more cameras, coverage to all nursing homes in the county, a TV repeater so that mobile units could be utilized, and (get this) televising in *color*. Fortunately, Mother Nature interrupted these discussions before they got out of hand by providing a drenching downpour exactly 15 minutes after the parade ended.

Besides giving the small Marshall County Amateur Radio Club a project on which to work together, the project – more importantly – provided some of our senior citizens with a little happiness and a break in the daily routine.

Each of the nursing homes made formal comments to the local newspaer, and a representative from the National Nursing Home manned by WB9GSI sent in the following: "It was just fabulous! We were so glad we were included and it gave our employees a chance to see the parade also. The men coming in beforehand to set everything up gave the patients a great deal of enjoyment. If the club ever tries to do this again, we hope they think of us."

. . .W9JER

entry had disappeared down the street, everyone chipped in and began disassembling what to our mind was the greatest thing that ever happened to Marshall County. All reports from the nursing homes were superlative, not only from the hams stationed there, but also from the patients and staffs.

Even before the equipment was fully disassembled, talk turned to how we could improve the system next year . . . such as

Mystic CT 06355

THE MODIFIED SUCTION-CUP ANTENNA

A few simple modifications to the original suction-cup antenna provide greatly simplified tuning. The modifications also permit the antenna's tuning network to be used as an antenna coupler for random-length single-wire antennas, thus further extending the versatility of the unit as a simple, multiband, portable antenna.

The original suction-cup antenna consisted of a surplus folding whip antenna about 10 ft long with a loading coil at its base. It was intended for quick setup, particularly on an automobile, whenever a multiband antenna was desired for temporary operation. Apparently, the idea was appealing to many amateurs who wanted some portable operating capability while on vacation or some other trip but didn't want to install a regular mobile antenna installation. The whip and coil were wired together as shown in Fig. 1 (A).

The main objection that was heard about the antenna was the difficulty involved in finding the two correct coil tap positions, particularly when large frequency excursions were made. Although a procedure was outlined for finding the positions, many amateurs apparently found the procedure too time-consuming when they simply wanted to set up for portable operation for a short period of time. Various means were explored to simplify the tuning of the antenna. Details are given on one method that lends itself to simple modification of the original antenna and other methods are mentioned for the benefit of those who might like to construct a suction-cup antenna for the first time and, therefore, have more freedom in the placements of the tuning components. With the modification, tuning becomes a matter of simply tuning a variable capacitor instead of adjusting two coil tap positions. Generally a single coil tap position need only be changed when changing bands.

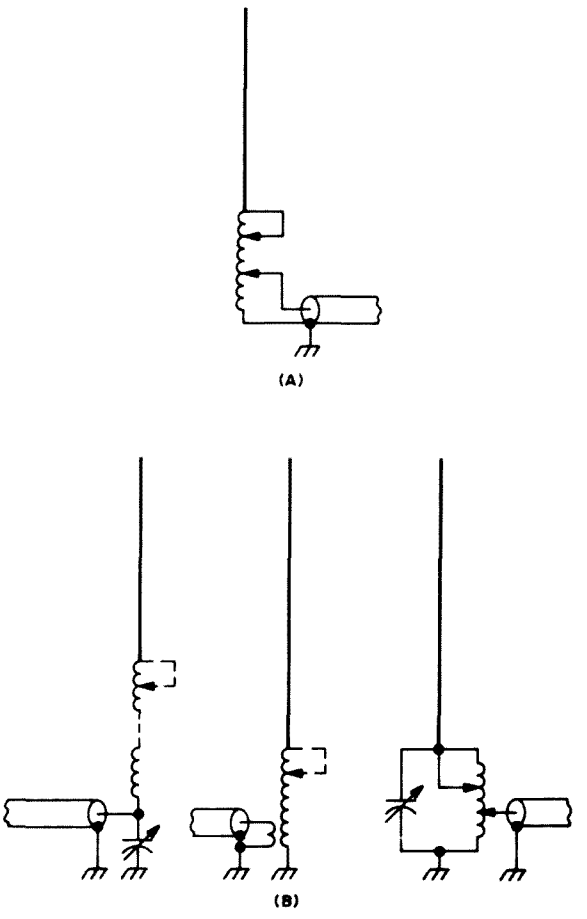

Fig. 1. The basic antenna loading scheme (A) and three networks which were considered in order to provide simplified single-band tuning (B).

Tuning Methods

There are several ways by which the coil taps shown in Fig. 1 (A) can be replaced for single band operation by a continuous tuning scheme. Some of these possibilities are illustrated in Fig. 1 (B). The simplest scheme is probably that there a variable capacitor is placed from the coax center conductor to ground and an extra inductor added to the basic whip loading coil. The extra inductor and the capacitor form an "L" network which can be tuned as desired to match the loaded whip. Although the scheme is generally simple for new construction, since only one inductor need be used which combines the loading and "L" network inductances, it does have a disadvantage in that the variable capacitor has to be fairly large. In fact, several thousand mmf may be required on 80 meters for a 10 ft whip. Fixed capacitors can, of course, be paralleled with a wide range variable capacitor. Another possible scheme is to leave the coil taps as in Fig. 1 (A) but use a 100–200 mmf variable capacitor across the entire coil. Such a scheme will eliminate the need to change the upper coil tap for operation over most of one band but the capacitor is subject to a fairly high voltage gradient and has to be a wide-spaced type for any appreciable transmitter power. The best compromise scheme seems to be that shown in the middle of Fig. 1 (B). Link coupling is used to couple to the loading coil in order to eliminate the transmission line coil tap. The series capacitor modifies the effective coil reactance so that adjustment of the one coil tap left is only needed for bandswitching. A capacitor of 250–325 mmf and medium spacing is sufficient for medium power transmitters.

Modified Antenna Construction

Figure 2 shows how the original suction-cup antenna was modified. Note that the ground end of the loading inductor is actually at the top of the inductor. As in the original, the coil is supported by two metal brackets (homemade of thin brass or copper strap) attached to the lower whip section. An additional bracket is added to support the variable capacitor (a Hammarlund RMC type unit). The capacitor has two threaded mounting holes on the bottom (not insulated from the frame or rotor). A screw is used directly to attach the lower whip bracket to the capacitor.

Since the middle bracket carries the mounting screw for one of the automobile top carrier-type suction cups, a small flat metal bracket about 1 in. long is used to offset the capacitor mounting from the bracket. Instead of depending solely upon the bracket's electrical contact to the whip, a No. 10 piece of wire is also run from a ground lug on the lower mounting hole on the capacitor to the terminal connection at the bottom of the whip. The lower end of the loading coil is connected to one of the stator terminals of the capacitor. About an 8 in. piece of wire with an alligator clip is connected to the other stator terminal in order to effect bandswitching by shorting out portions of the loading coil.

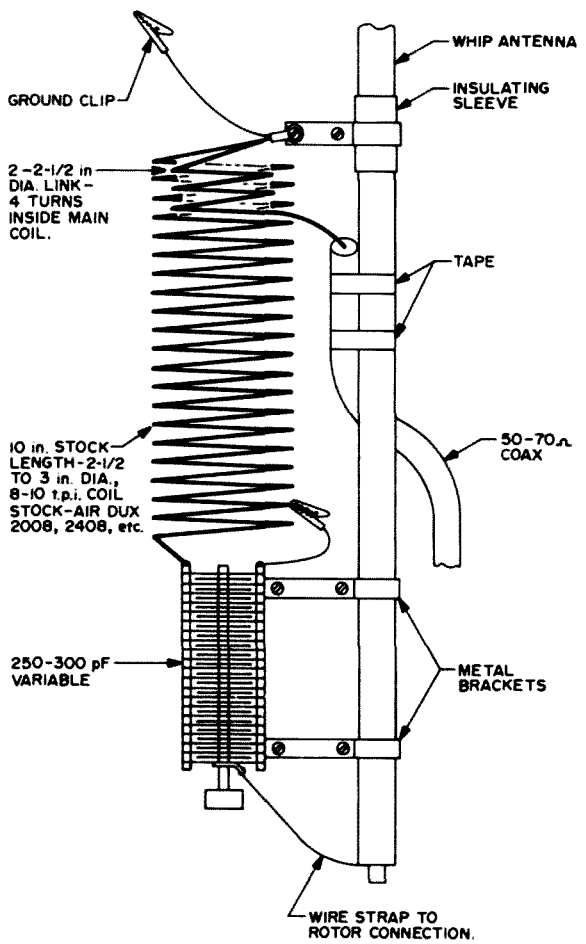

Fig. 2. Construction of the tuner components on the lower section of the whip. The suction cups, attached to the top two metal brackets, are not shown.

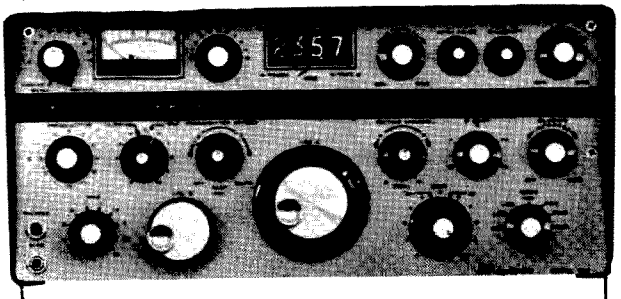
The coaxial transmission line coupling link is made of a piece of standard coil stock one diameter smaller than that of the loading coil. It fits easily within the top portion of the loading coil and is cemented in place by Duco cement used between the ribs of the two different diameter coil stocks. The coaxial transmission line is taped to the whip antenna rod, as shown in Fig. 2, with the inner conductor connected to the link coil and the shield to a lug on the upper whip bracket. Care must be taken that the shield of the transmission line is insulated from the whip antenna where it is taped to it for mechanical support.

The foregoing paragraphs were not intended to provide an extremely detailed description of the antenna's construction but mainly to highlight those areas which might require clarification. The use of components of widely different manufacture or construction will yield the same results but the same basic construction techniques should be observed.



Adjustment

Proper adjustment of the antenna requires, at least initially, the use of an swr meter placed in the transmission line as near to the antenna as possible. The capacitor should be set at its mid-scale value. On any selected frequency band, the band coil tap on the loading inductor is then experimentally determined to produce the lowest swr. Varying the capacitor setting will then allow operation with the same coil tap position over a major portion of any low-frequency amateur band. Once the correct coil tap position has been found for a band, it is not necessary to monitor the transmission line swr. The variable capacitor can simply be adjusted for maximum field-strength indication response using the coil tap determined to be correct for mid-band operation. If desired, once the correct coil tap position for a band has been determined, a pin and jack arrangement can be used for band-switching. Standard banana-type plugs and jacks, for instance, are very suitable. The jacks are soldered on the coil at the correct mid-band position, as determined by swr measurements, and the alligator clip shown in Fig. 2 replaced by a banana plug.

CX7A

by signal/one

Features:

- RELIABILITY IS NOW standard equipment. Every CX7A "burnt-in" and cycled more than 48 hours.
- QUALITY-PLUS. Every component is instrument grade. American-made, and individually tested.
- ALL MODES 10 thru 160 meters in full 1 MHZ bands with overlaps.
- BROAD-BAND TUNING. Instant band changes without tuning.
- TRUE BREAK-IN CW with T/R switching.
- IF SHIFT – deluxe QRM slicer.
- PRE-IF NOISE-BLANKER that really works.
- RF ENVELOPE CLIPPING – sounds like a Kw.
- TWO VFO'S Transceiver Plus receiver.
- BUILT-IN: Spotter, FSK shift, transmit offset, wattmeter, SWR meter, electronic CW Keyer.

Specifications:

- SENSITIVITY: Better than 10db signal-plus-noise-to-ratio for .25 microvolts at 28 MHZ.
- SELECTIVITY: 2.4 KHZ @–6db, 1.8:1 (6:60db) shape factor. (16 pole crystal lattice Filters) optional: CW-300 and 400 HZ. FSK-1200 HZ.
- CARRIER and unwanted sideband suppression. Minimum 60db.
- IMAGE and IF REJECTION: more than 60db.
- POWER LEVEL: 300 to 500 watts p.e.p. plus, continuous duty cycle.
- POWER AMPLIFIER: 8072 final completely broad-banded driver and final. 150 watts continuous dissipation rating.

It's Perfection for $2195

Typical installation of the modified suction-cup antenna. Placement of the tuning capacitor at the bottom facilitates ease of tuning. Use of a Mueller 63C insulated clip instead of the uninsulated type shown is preferred.

Summary

The suction-cup antenna can easily solve the antenna problem for many temporary or portable operating situations. With variable tuning, the basic antenna becomes even more versatile and easy to adjust. A very handy feature of the modified antenna is its ability to serve also as an antenna coupler. For instance, if one is in a portable situation where it is possible to erect a long-wire antenna for greater efficiency, the tuning network of the suction-cup antenna can be quickly converted into an antenna coupler for the long-wire antenna. A shorting connection (by means of clip-on leads) is made from the rotor terminal of the variable capacitor to the upper (ground end) terminal of the loading coil, thus forming a parallel resonant circuit. The long-wire antenna terminal is then tapped on the main coil at a point producing minimum swr in the coaxial transmission line with the parallel resonant circuit peaked for maximum transmitter loading. Almost any random length of long-wire antenna can be easily tuned in this manner.

300 MHz FREQUENCY SCALER

This summer 73 Magazine is publishing a three-part article on building an IC frequency counter good up through the VHF range. That design has a built-in frequency scaler, and is good through almost 300 MHz. For those who have a low-frequency counter and just need a scaler to extend the range, here is a simple design which can be built for about $20.

The heart of the unit is a Fairchild μ6B95H9059X divide-by-10 scaler IC, which costs about $16 in unit quantities; we call it a 95H90 for short, and it's IC1 in Fig. 1, the schematic diagram. The output of this IC is fed into a 2N5771 PNP transistor which amplifies the output and provides a voltage change. If you have a counter which will go up to about 15 MHz, then this part alone will extend your range to 150 MHz. But if you have a slower counter, then you will need IC2 as well. This is an inexpensive ($1.30 or so) SN7490N TTL decade counter, which does a second division by 10. Both IC's together will take a 150 MHz signal and divide it down to 1.5 MHz.

The IC's need a voltage between +5 and about +5.3 volts. While you could build a power supply, that only increases the cost. The easiest way to provide power is with four D cells or a 6-volt lantern battery, which provides +6 volts. The 1N4001 diode, or another silicon power diode, drops this to about +5.3 volts. The scaler needs about 150 mA, so a set of four D cells will last about 10 or 20 hours with intermittent use.

Figure 2 shows a printed circuit board layout which can be used to mount the scaler, and Fig. 3 shows the parts placement on the board. Leave the copper border around the board, to act as the ground connection for the board. Use phono jacks or rf connectors, and bypass the +6 volt lead. The purpose is to let rf into the box only via the input lead.

In use, avoid over-driving the scaler. Start with a low input level, and feed in just

73 REVIEWS THE SAVOY BASSET VACUUM TRAP ANTENNA SYSTEM MODEL DGA-4075

When you open the box of the DGA-4075 you know instantly that the new Savoy Basset Antenna is made of full commercial grade parts. Quickly reading through the instructions you find that no soldering is required during assembly. All you need is a screwdriver, pliers, diagonal cutters and a tape measure. In fact you don't even need end-insulators as the nylon support line supplied with the antenna works perfectly.

Savoy supplies two very simple charts that are used to determine the length of the two sections of wire. First you pick your 40 meter center frequency to get the "A" wire element dimension. Then use that same frequency on the vertical side of the 80 meter chart. Where the 40 meter frequency and 80 meter frequency intersect on the chart gives you the second dimension for the wire sections. Now you have the two dimensions for the wire on each side of the traps. There is only one trap on each leg. The wire that Savoy supplies with the antenna is not the usual stranded type but the heavy duty copperweld solid type. Also included is a center insulator that is a broadband balun. The lead-in coax that comes attached to the balun is a half wave length on 80 meters. The feed line can even be pruned to make it an exact half wavelength at your specific 80 meter frequency. After shorting each wire element the amount shown by the frequency chart, you simply place the wire ends into the clamps on the traps and balun and tighten down the set screws – and you don't even have to strip the wire! After you have all of the wire sections together, put a support rope through the center insulator and hoist it up to the support point. Find a place to secure the nylon support ropes at the ends and you are almost ready to go. Once you run the RG-59/U feed line into the shack, the only soldering you have to do is to put on a PL-259 male coax plug along with a UG-175/U reducing adapter. That's it – all you have to do now is fire up the rig and get on the air.

In the past I have had the unpleasant experience of trap failure on both dipoles and verticals. This usually occurred while running a full KW on RTTY. Not only would the trap go but usually the final tube, too, unless I happened to catch it very quickly. When you open the box in which the DGA-4075 was packed, you are immediately aware that the traps are quite a bit larger than the two-inch types usually found on most trap dipoles. The traps supplied by Savoy are a good four inches in diameter and are hermetically sealed in heavy, clear plastic containers. When the trap coils are placed in the containers at the factory the normal air is removed and replaced with helium. This prevents any chance of moisture getting into the traps and causing a breakdown or arc-over. The larger diameter trap coil design allows the traps to have a higher Q which means that the overall antenna performance is better.

The Savoy DGA-4075 easily withstood a full KW input on RTTY and with an SWR of 1.3 to 1 on 80 meters. In fact, I cranked the Heath SB-220 up to produce a *broadcast* type of KW and the antenna took it with no problem. The same thing was tried on phone on 40 meters with equally excellent results. In fact the antenna works so well I will probably get the conversion kit Savoy offers to convert it to be used on 20 meters as well. All you do is add two more traps and you have a high power tri-band trap dipole. Of course Savoy offers a DGA 204075 right from the factory if you want a tri-bander from the start.

I am very happy to see Savoy offer an antenna of this quality and performance – it has been long overdue for the ham who wants to run high power on the lower frequencies with one antenna. The assembly constructions are clear and concise and contain a number of examples of how the antenna can be installed in various configurations. Savoy even has reflector and director kits, should you want to make up a wire beam. The DGA-4075 is a mere $49.50 and the DGA-204075 only $79.50. Other band combinations are available. Write to *Savoy Electronics, Inc., P.O. Box 7127, Fort Lauderdale FL 33304.*

73 REVIEWS THE VANGUARD FS-160 FREQUENCY PRESCALER

In addition to the many solid state VHF/UHF preamplifiers and converters that Vanguard Laboratories make, they have entered into a new product line: a VHF prescaler. The model FS-160 is a prescaler or decade frequency divider that is guaranteed to operate up to 160 MHz. This means if you want to measure your 2m FM rig's frequency and have a counter that will read up to 15 MHz, all you need is the FS-160. The prescaler will divide your 146.340 MHz by ten and allow your counter to read 14.340 MHz. In the process of dividing you will lose the "ones" or Hertz digit resolution. It is impossible to *accurately* set a VHF transmitter to within ±10 Hz so you are not missing the performance of higher priced VHF counters. But you have gained a useful tool: you can now reset your transmitter frequency on 15, 10, 6 and 2 meters. Also the aircraft transmitter frequencies from 120 130 MHz and the business and marine frequencies from 150–158 MHz can be measured. The FCC requires your counter to be a high accuracy crystal time base so that you will meet the standards for these commercial frequencies. A first or second class radiotelephone license is required also.

By placing a short pick-up antenna to the input of the FS-160 prescaler and connecting the output to our Heath IB-101 counter, we have been able to read the frequency of hand-held portables up to a few feet away. Also, by placing the scaler and counter in the house pointing out the window to the driveway, we can very easily net the FM mobile rigs we have around. Receiver crystals can be netted on the bench by using a short piece of coax as an rf pickup by reading the local oscillator frequency in the 135–136 MHz range. This is usually 10.7 MHz below the desired receive channel frequency.

The FS-160 is all solid state with a two stage discrete wideband input amplifier and IC frequency dividers. The first IC is a high speed divide-by-two that feeds three more flip-flops arranged in a divide-by-five configuration. A discrete voltage level translator and buffer stage feed the signal to the counter after being divided by a final decade. The power supply is voltage regulated by an IC regulator controlling a series pass transistor. Input and output jacks are of the BNC style and there is a separate amplifier output jack provided. An ac power switch and pilot lamp are also on the front panel of this nice little package. Other prescalers for up to 500 MHz are also available. The FS-160 sells for $129.50. CARE AND FEEDING OF TAPE

Don Royer WA6PIR
16387 Mandalay Dr.
Encino CA 91316

For those who want to keep, store and retrieve tape, there seems to be several problems that are encountered. Having had these same problems for several years with about 25 RTTY picture tapes, a few tips may be in order.

Of the two types of punches, I prefer the chad type. Even though the little chads to get into things, the tapes are easier to wind, store, and to feed into the TD. But then, most of the punches are the chadless type, so I will try to cover both situations.

There are several types of commercial winders available. I have two of them – both motor driven. One is used for winding from the TD or reperf and the other for the necessary unwinding. On a long tape, I put the loose tape from the unwinder in a large wastebasket below the TD and then forget it, as it comes out fine. Chadless tapes may catch on themselves and require a bit of watching. In the absence of a winder, you can learn to wind the tape in a figure eight about your thumb and little finger with the start at the beginning of the bundle. In this way, the tape will not be twisted and will pull off the tape bundle with but a little help from you. To keep the ends free and windable, I usually pull about a foot of blank tape from the reperf at both ends. If you are thinking of building a winder, try to keep the center hub at least three inches in diameter as too tightly wound tape resets the chads in the chadless type back where they were and will not permit it to run properly in the TD. If you use the figure eight wind, tuck the free end into the bundle loop. With rolls from the winders, I like to use a small bit of solder to hold the roll together. If you have trouble learning to figure eight wind, get a local commercial Teletype gal to show you the simple technique.

Storage and retrieval are the real problems. I separate the tapes into subjects and store them in large plastic bags with ten or fifteen tapes to a bag. This keeps the tapes from drying out and lets me find any one tape without too much time. The title of the material on the tape, marked on the lead end with a heavy marking pen, also helps to speed identification. Making and keeping a list of the tapes in the same order as stored also helps and can be used to tell the others what you may have on hand that may be of interest to them. The marking pens will also write on the plastic bags that can then be stored in a drawer or cabinet.
